CONTROL OF ACCIDENTAL POISONING—A PROGRESS REPORT

Howard M. Cann, M.D., Dorothy S. Neyman
and
Henry L. Verhulst, M.S., Washington, D. C.

ALMOST five years have elapsed since the first poison control center in the United States was established in the city of Chicago. During this period a number of developments have contributed to progress against accidental poisoning.

Probably the most noteworthy of these developments is the realization by the medical profession, especially by pediatricians, that accidents constitute a major health problem. This recognition is shown by activity in research, clinical medicine, and public health. Progress in treatment of accidental poisoning, morbidity data from poison control centers, and prevention aspects of the problem will be presented in this paper.

Accidents constitute a major health problem, and the prevention of accidental poisoning is an important phase of it. There are now, in the United States, 200 centers actively working on the prevention of deaths from this cause. Their functioning is illustrated by three case histories. A total of 3,926 cases of actual or potential poisoning have been reported to the National Clearinghouse for Poison Control Centers and are here analyzed. Ingestion of medicine accounted for 55% of these cases, the most frequently ingested medicine being acetylsalicylic acid. Data on 7,023 deaths due to accidental poisoning have also been analyzed by the U. S. National Office of Vital Statistics; they show that the importance of salicylate as a poison declines in the older age groups and that in the national experience barbiturates caused 50% of all accidental deaths from drugs. Research has led to the development of new drugs and new methods of treatment. Poison control centers supply up-to-date information on treatment and toxicity to physicians and are in a position to encourage education and research as part of the program of prevention. The private physician must play an important role not only in the treatment of accidental poisoning but also in its prevention.

Research in Treatment

Better understanding, recognition, and management of poisoning have followed the increasing research in recent years. We wish to mention a few findings pertinent to accidental poisoning.

Artificial Kidney and Exchange Transfusion.—The artificial kidney has been used with promising results for treatment of severe poisoning from salicylates, barbiturates, and glutethimide (Doriden), as well as intoxication from bromides and thiocyanates, and for treatment of acute renal failure from poisoning by nephrotoxic substances, such as carbon tetrachloride and mercuric chloride.[1] Experience with hemodialysis in some centers has been such that specific indications for this procedure have been proposed. The lack of experienced hemodialysis teams limits the wider use of this procedure for the treatment of acute poison-

ings, especially for the management of children. More centers with personnel well trained in the use of the artificial kidney are developing, and we hope that this procedure will be applied more frequently to children and may be expanded to treat poisoning by many more toxic substances than those mentioned above.

Exchange transfusion also is being employed in the management of acute poisoning in children—especially in the treatment of severe salicylism.[2] The results seem promising, but more experience is needed for evaluation. In addition to salicylate intoxication, boric acid, isoniazid, sodium nitrite, and iron poisoning have been treated in this manner.

We would like to see further investigation with not only the artificial kidney and exchange transfusion but also intermittent peritoneal lavage[3] and the ion-exchange resin "kidney"[4] so that criteria for such therapy will become better established and factors for selecting the method of dialysis further defined.

Bemegride.—Continued search for antidotes has produced some drugs which must be mentioned. The controversy concerning the treatment of barbiturate intoxication—supportive and symptomatic treatment versus analeptic therapy—is well known. British workers have reported that bemegride (3-ethyl-3-methylglutarimide) has a seemingly direct antagonism to barbiturates,[5] but more recent studies have failed to confirm such action. The drug is apparently an analeptic with a high therapeutic index, the effects being more rapid in onset than those of picrotoxin.[6] British investigators now feel that the drug is safe and report clinical antagonism to not only barbiturates but also many nonbarbiturate hypnotics.[7] Schreiner and co-workers[8] have demonstrated functional antagonism of this drug to glutethimide clinically and recommend its use in moderate and severe glutethimide intoxication. Studies also have been carried out with bemegride incorporated into barbiturate capsules.

Whether or not this drug is as effective as its proponents believe, its introduction may have improved therapy of barbiturate poisoning by stimulating proponents of supportive and symptomatic management to action. Recent studies suggesting the superiority of supportive therapy, that is, support of depressed respiration and circulation, provision of maintenance fluids and electrolytes, and close observation and good nursing care, are impressive.[6]

Tranquilizer Intoxication.—The tranquilizers are in wide use today, and, as is to be expected with such a widely used group of drugs, the problem of poisoning from accidental or intentional overdosage has appeared. It now appears that large doses of chlorpromazine hydrochloride are capable of producing convulsions in certain individuals,[9] in addition to central nervous system depression. Methylphenidate (Ritalin) hydrochloride, a central nervous system stimulant, has been used in cases of coma caused by overdosage of chlorpromazine, meprobamate, or other tranquilizers.[10] Although we have reservations about using any central nervous system stimulant to treat intoxication by a drug capable of producing convulsions (such as chlorpromazine), further reports concerning the effectiveness of methylphenidate in treating acute tranquilizer-agent intoxication are to be awaited with interest.

Edathamil Calcium-Disodium.—The chelating agent, edathamil calcium-disodium, (Ca-EDTA) should be mentioned. To date this drug is the best agent against lead poisoning available, but its use has not significantly reduced mortality from lead poisoning in children.[11] A period of 48 to 72 hours of administration of this drug is usually required to reduce to less toxic levels potentially lethal concentrations of lead present in the tissues. It is in this period, after the onset of symptoms, that most deaths from acute lead encephalopathy occur.

It would appear that the incidence of neurological sequelae from lead poisoning may have been reduced by edathamil calcium-disodium therapy, but in children there is no substitute for prevention of exposure to lead and the early diagnosis of lead poisoning. Investigation for lead poisoning should be done in any child under the age of 5 years with a history of pica and present complaints of gastrointestinal symptoms, behavior change, or convulsions without a previous convulsive history.

Anticholinesterase Intoxication.—Possibly the most exciting work has taken place in the area of anticholinesterase intoxication. The anticholinesterase compounds are used as insecticides and in the treatment of myasthenia gravis. With the emergence of resistance to chlorinated hydrocarbon insecticides, the organophosphorus anticholinesterase compounds are being used with increasing frequency. Intoxication from improper use and from accidental ingestion has been reported. The development of quaternary ammonium anticholinesterase compounds with an intermediate duration of action has improved the treatment of myasthenia gravis, but again intoxication from these compounds occurs. Anticholinesterase poisoning produces muscarine-like, nicotine-like, and central nervous system effects. These occur from the accumulation of acetylcholine at postganglionic cholinergic nerve endings, at the myoneural junctions, and in the central nervous system.

Treatment includes maintaining a clear airway, artificial respiration because of paralysis of respiratory muscles, and atropine against the muscarine-like effects. Atropine has no effect on the muscular weakness or paralysis. It appears that a group of compounds known as oximes may reverse the neuromuscular block and the plasma and erythrocyte cholinesterase inhibition and decrease the generalized weakness seen in patients with anticholinesterase intoxication. The oximes do not seem to alter the muscarine-like effects.[12] Atropine plus an oxime compound (pyridine-2-aldoxime [PAM] or diacetyl monoxime [DAM]) may prove to be an effective combination and may diminish the need for or the duration of artificial respiration in the treatment of anticholinesterase poisoning. The oximes are still being investigated. Thus, they are not yet available for general use.

Research in Action of Poisons

We now turn from new possible antidotes to modes of action of particularly poisonous substances. Studies of hemolytic anemia resulting from poisoning by various agents have revealed erythrocyte enzymatic defects in "susceptible" individuals. The erythrocytes of those individuals who develop acute hemolysis subsequent to ingestion of naphthalene, ingestion of the fava bean or inhalation of pollen from the plant, or ingestion of primaquine phosphate have been found to have a deficit of glucose-6-phosphate dehydrogenase activity and a low level of glutathione.[13] Incubation of these erythrocytes with acetylphenylhydrazine results in a marked fall of reduced glutathione. Further studies show that the defect is genetically determined and probably transmitted by a sex-linked gene. This work explains the occurrence of acute hemolysis in only some of those individuals who have ingested naphthalene, the fava bean, or primaquine and may lead to a better understanding of other hemolytic anemias.

The recent development of a quantitative chemical analysis for the aromatic fraction of kerosene in venous blood [14] is important. It should give more information about the pathophysiology of kerosene poisoning and lead the way to a more effective and uniform therapeutic regimen for petroleum distillate ingestion.

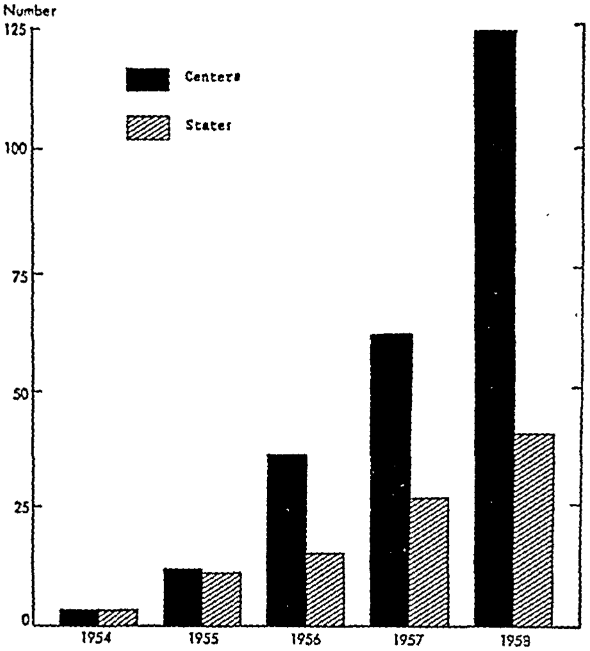
We have mentioned only a few of the more recent advances in the understanding and treatment of poisoning. It is gratifying that more work has been and is being carried out in this field. However, many problems remain unsolved. There is a need for the development of more inexpensive, less time-consuming analysis procedures for the detection of the more commonly involved poisonous substances. Certainly, more research into the pathophysiology produced by toxic substances is necessary so that rational and effective methods of therapy can be instituted.

Poison Control Centers

When, in 1953, the first poison control center was organized in the city of Chicago under the sponsorship of the Illinois chapter of the American Academy of Pediatrics, physicians, especially pediatricians, had long needed a central information agency where data on the toxicity, ingredients, and treatment of poisoning by potentially toxic trade-name products could be obtained. Cincinnati, Boston, Grand Rapids, Mich., and Washington, D. C., organized poison control centers thereafter.

The figure shows the growth of poison control centers in the United States. As of April, 1958, there were 128 poison control centers in 40 states and territories. There are now about 200 such centers operating in the United States.

These centers are active in the various phases of poison control. Information concerning the identity and toxicity of ingredients in trade-name products and other substances and current methods of treatment for various types of poisoning are available to physicians. If a nonmedical person calls for help, first-aid instructions are given, with advice to contact a physician. The centers receive an average of 18 calls per week. Most of the centers maintain 24-hour telephone service.



Growth of poison control centers, 1954 to 1958. Graph includes centers in all states, District of Columbia, Alaska, and Hawaii known to be in operation on April 1 of each year. Those centers once established but no longer in operation are not included.

Eighty-five per cent of the centers have facilities for treatment. The remaining centers furnish informational services only, but treatment is available at nearby cooperating hospitals. It should be remembered that poison control centers are not the only loci for emergency treatment of poisonings. Any well-equipped emergency room should be able to administer proper, indicated emergency treatment for poisoning.

Some poison control centers are carrying on studies in epidemiology,[15] treatment, and pharmacodynamics. Sixty-six per cent of the centers do nent by us. Accidental ingestion involving only the victim (usually a pre-school-aged child) accounted for 92% of all cases. Overdosage on the part of a physician or an individual other than the victim and misidentification of a substance (e. g., camphorated oil for castor oil) accounted for less than 5%. Intentional ingestion accounted for 5% of all cases.

Consideration of the time of day that ingestion occurred revealed 87% of all cases occurred between 7 a. m. and 8 p. m. Information on the time which elapsed between ingestion and lavage was available in 1,336 of 3,926 detailed case reports. In 54% of cases in which lavage was done, this treatment was instituted within one hour of ingestion. In only 3% of these cases a delay of longer than four hours occurred.

In about 2,500 cases information concerning the development of signs and symptoms of poisoning was available. Approximately 70% of the patients were reported as asymptomatic. Eight per cent of 2,400 for whom information on hospitalization was available were hospitalized for one or more days.

TABLE 5.—*Summary of Fatal Cases Reported by Poison Control Centers in Twenty-nine Areas**

Substance	Age	Sex	Race	Intent
Analgesic with salicylate........	27 mo.	F	W	Accident
Kerosene	13 mo.	M	N	Accident
Kerosene	16 mo.	M	W	Accident
Insecticide	14 mo.	M	W	Accident
Bichloride of mercury...........	42 yr.	F	W	Suicide
Natural gas	48 yr.	F	Unknown	Suicide
Unknown†	43 yr.	F	W	Suicide
Unknown†	Unknown	M	Unknown	Accident

* For various time periods from July, 1956, to April, 1958. Source: individual case reports submitted to the National Clearinghouse for Poison Control Centers.

† Evidence of poisoning on clinical basis only.

Follow-up Data.—Of the 3,926 detailed reports, 551 cases were further investigated by home follow-up. In 36.5% of these 551 cases, the offending agent was not in its original container before ingestion; the figure was significantly higher for petroleum distillates and pesticides. Bottles, cans, drinking glasses, and cooking utensils were containers different from the original in which some of these ingested substances were found.

In 68% of these cases, the substance was not found in its customary storage place. The ingested substance was found on a dresser or table in one-fourth of the cases and on the floor in 13% of cases. Moreover, the customary storage place for these substances was reported as an open shelf in 12% of the cases, a dresser or table top in 10%, and the floor in 6%.

In 216 cases (41%) the harmful or potentially harmful substance was found in the kitchen, in 113 (21%) in the bedroom, and in 66 (12%) in the bathroom.

Parents were supposedly supervising activity in 85% of the cases involving children. In 10% the supervising individual was an adult other than the parents. In only 5% of the cases the child's activity was supervised by other children or was unsupervised.

Comment

It is difficult to measure any success brought about by activities discussed in this paper in lowering the incidence of accidental poisoning. The data presented are definitely not national data, nor can they be extrapolated to arrive at national data. We are considering a selected group—those cases which came to the attention of local poison control centers in certain areas of the United States. Additional cases of accidental ingestion probably occurred in these areas but were not brought to the centers' attention.

The figures presented indicate that, as has been noted by Bain[18] and by others,[15] drugs, petroleum distillates, pesticides, and household preparations are the most commonly ingested products. Drugs accounted for one-half of all substances involved, with salicylates alone accounting for one-fourth of all ingested substances. These figures reflect the presence of medicaments, especially salicylates, in the home and their availability to children.

The differences between the distribution of drug ingestions treated by poison control centers and the distribution of drug ingestions reported as telephone calls to the centers for information is probably explained by the fact that physicians are familiar with salicylates and barbiturates and usually do not have to call for assistance in determining the nature and toxicity of these drugs. This is probably true for petroleum distillates also. However, the larger percentage of telephone inquiries for information about various household preparations and cosmetics (as shown in table 3) indicates the need for assistance in ascertaining the nature and toxicity of these substances. We suggest that the wide difference between cosmetic ingestions treated at the centers and those cases resulting only in calls for information is further a result of the generally lower toxicity of this group.

The data from poison control centers appear to support what others have pointed out: the hazard of accidental poisoning to pre-school-aged children who gain much knowledge by oral exploration of anything and everything.

It is interesting that the hospitalization rate was less than 10% within the group. For every fatal accidental poisoning, about 750 nonfatal accidental ingestions occurred in the reported group. This ratio differs from the often quoted 1:250 but is probably more accurate in the light of recent accident morbidity reporting.

The delay of more than one hour between ingestion and lavage in about 50% of the cases may indicate a lack of concern or understanding of the possibilities by parents. Many parents do not seek medical attention until obvious symptoms occur.

For instance, the latent period between ingestion and onset of symptoms in methyl salicylate poisoning emphasizes the danger in delay because the child does not immediately become ill.

We have noted with interest the recommendations on first-aid measures for poisoning adopted by the Committee on Toxicology of the American Medical Association. In view of the delay between ingestion and lavage in about one-half of cases, we suggest that parents be advised to contact a physician at once after a child's ingestion of a toxic or potentially toxic product. This advice should be modified according to the availability of medical care in the area.

The control of accidental poisoning must be effected by a dual approach—prevention plus improvement in all aspects of diagnosis and treatment. Improvement has been discussed in this paper in the sections on research and poison control centers.

The beneficial effects of drugs, soaps, detergents, bleach, pesticides, and petroleum distillates are not disputed. Prevention should be directed toward avoiding misuse of these substances. Proper storage in the home, with respect to container and location, should be emphasized in educational campaigns.

Educational campaigns must be directed predominantly to parents of pre-school-aged children. Modification of the environment of these children to achieve complete protection from toxic or potentially toxic substances is the practical end of such campaigns. Physicians have an important responsibility to educate parents in this manner. Examinations of the well child during infancy present an opportunity in which "safety vaccine" may be administered. These measures may be emphasized by writing prescriptions for small amounts of medication where feasible and by instructing the pharmacist to add to the label the words, "Keep out of the reach of children."

Other methods of prevention include organized educational campaigns on a community level, utilizing mass media and the spoken word. Such campaigns have been and are being carried out by local medical societies, health departments, poison control centers, and civic groups.

Industry has been quite concerned with the problem. As a result, work on the development of a safety closure for medicaments (and perhaps other types of products) is being done, mainly by the drug industry.

Precautionary labeling is another approach to the problem of prevention. Not only medical and public health workers are working in this field but also members of industry. Some states and cities have already adopted precautionary labeling laws.

The work of the Food and Drug Administration of the U. S. Department of Health, Education, and Welfare and the U. S. Department of Agriculture along the lines of prevention of misuse of drugs, caustics, and pesticides by enforcing proper labeling is another example of a type of prevention being undertaken.

In some universities consideration of the factors involved in accidental poisoning has been included in the undergraduate and graduate medical curriculum. Thus, future practitioners of medicine are becoming oriented to a common pediatric problem. We hope that, eventually, all medical schools will include the problem in their curriculums.

The controlling of accidental poisoning should not be looked on as an end in itself. The larger goal is accident prevention in general. The lessons being learned in dealing with accidental poisoning should be applied to other types of accidents. Burns, drowning, and foreign body aspiration are certainly three childhood accidents on which more attention should be focused. Already some poison control centers are extending their activities to include other types of accidents. This is the logical direction in which to proceed.

Summary

Work in public health and clinical medicine and research into pharmacodynamics of and pathophysiology produced by poisonous substances are increasing the effectiveness of treatment methods. As of April, 1958, there were 128 local poison control centers in 40 states; now there are about 200. These local centers aid physicians in the treatment of accidental poisoning by providing information about the nature and toxicity of ingested substances and the treatment of poisoning from these substances. Treatment facilities are usually available at these local centers also. All centers recognize the importance of prevention through education in dealing with accidental poisoning.

About 4,000 cases of accidental ingestion and poisoning were reported to the National Clearinghouse for Poison Control Centers from 29 poison control centers that are located in the eastern and midwestern parts of the United States. These reports, with figures on accidental poisoning deaths obtained from the National Office of Vital Statistics, show that drugs (which accounted for about 50% of all ingestions), household preparations, pesticides, and petroleum distillates were the most commonly ingested products. Pre-school-aged children were involved in 86% of cases reported from poison control centers and in 28% of accidental poisoning deaths reported by the National Office of Vital Statistics.

Five accidental deaths occurred in the poison control center series, giving a ratio of 1 fatal to 750 nonfatal accidental ingestions. Approximately 70% of the patients in about 2,500 cases in which information concerning the development of signs and symptoms of poisoning was available were reported as asymptomatic. Eight per cent of those in 2,400 cases in which information on hospitalization

was available were hospitalized for one or more days. In about 50% of patients on whom lavage was done, a delay of longer than one hour occurred between ingestion and lavage.

Follow-up data indicate that proper storage of potentially toxic substances must be emphasized in educational campaigns directed toward parents of pre-school-aged children. Such education must be directed from physicians to parents. Community educational campaigns by local medical societies, health departments, poison control centers, and civic groups should reinforce this important physician activity.

Other aspects of prevention include precautionary labeling and development of safety closures. Industry and the medical profession are active in these endeavors. The control of accidental poisoning is a means to an end—the control of all accidents.

RESULTS OF TREATMENT IN VARIOUS CLINICAL SYNDROMES.—In the over-all clinic population and in the group of patients diagnosed as having psychoneurosis, the results of therapy by internists who place special emphasis on alleviating stress in the patient's life compare favorably with reports from other clinics where the treatment is carried out by trained psychiatrists. The data indicate that, in the hands of a sympathetic, sincere, informed and well trained physician, approximately two thirds of the patients will recover or show considerable improvement, and one third will show no improvement. . . . In certain disease entities—namely, peptic ulcer, ulcerative colitis and asthma—results of therapy by those who made protracted efforts to alleviate stress in the patient's life were better than they were in the hands of those who did not; as to peptic ulcer, the results were better than they were with those using psychoanalytic therapy. In addition, with these patients, frequently less time was required to be spent with the patient than when the physician concerned himself almost entirely with diet and medication. In the initial months of this type of treatment, more time is spent with the patient than in the more usual therapy. However, over a period of a year less time is often spent. It is possible that the one third of the patients showing no improvement represent the group of patients for whom there is no effective therapy at the present time. The findings show that internists, psychiatrists and psychoanalysts are all effective to the same extent in the treatment of psychoneurosis.—W. J. Grace, M.D., R. H. Pinsky, M.A., and H. G. Wolff, M.D., Results of Treatment in Various Clinical Syndromes, *Annals of Internal Medicine*, May, 1958.

MANAGEMENT OF ACUTE VENOUS THROMBOEMBOLISM

William G. Anlyan, M.D., George D. DeLaughter Jr., M.D.

Jacob I. Fabrikant, M.D., John W. Sullenberger, M.D.
and
William T. Weaver, M.D., Durham, N. C.

The object of treating acute venous thromboembolism is twofold: (1) to avoid fatal pulmonary embolism and (2) to minimize postphlebitic sequelae. A hypercoagulability state appears to be the basic etiological factor; this may be aggravated by intimal damage and venous stasis. Anticoagulant therapy is the treatment of choice. In patients who have been operated on, the legs should be routinely inspected at least twice daily for asymptomatic swelling. Vigorous treatment with heparin and elevation tends to minimize postphlebitic sequelae.

At the present time thromboembolism has become one of the major hazards after surgical operations, trauma, or parturition. In about 3% of patients undergoing major surgical operations, an increased tendency to clot develops in excess of the needs of the organism to prevent bleeding secondary to the surgical trauma; the etiology of this hypercoagulability is unknown, and the result may be venous thrombosis and pulmonary embolism.

In the past eight years one of us (W. G. A.) has seen over 500 patients with venous thromboembolism on the surgical and obstetric services of this hospital. This experience has provided a rational basis for the management of patients with venous thromboembolism.

Etiology of Venous Thrombosis

Intimal damage, stasis, and hypercoagulability are commonly listed as the etiological factors in venous thrombosis. In our experience, intimal damage and stasis appear to play a relatively minor role in the development of deep venous thrombosis. Patients occasionally develop thrombosis of the deep venous system of the legs after the prolonged use of an intravenous catheter in the long saphenous vein. The usual sequence of events is that the intravenous solutions are sufficiently irritating to cause a superficial venous thrombosis which may then spread through the communicating veins to the deep venous system. The routine use of 10 mg. of heparin sodium in each liter of fluid administered by this route has been of definite benefit in minimizing superficial and deep venous thrombosis. The majority of surgical patients, however, do not require the prolonged use of an indwelling venous catheter. The intravenous administration of fluids in the lower extremities is avoided whenever possible, which eliminates a major cause of intimal damage.

The role of stasis in the production of venous thrombosis is also controversial. There are clear-cut instances where venous stasis is produced unintentionally with resultant deep venous thrombosis, such as the use of an elastic bandage on the thigh without a wrapping below the knee. Stasis due to immobilization and bed rest has been incriminated, although only approximately 3 out of every 100 surgical patients develop deep venous thrombosis. In addition, early ambulation has not lowered the incidence of postoperative venous thromboembolism.

Hypercoagulability is a nebulous phenomenon that has been recognized by surgeons and physiologists to occur after trauma or surgical operations.[1] No measure of hypercoagulability is available except by changes in whole blood clotting time; no specific blood clotting factor known today has ever been shown to be present in amounts in excess of normal in hypercoagulability.

ACTH and cortisone administered intravenously appear to cause a definite shortening in silicone tube clotting times, although the precise site of action is conjectural (fig. 1). It is our present concept that the period of hypercoagulability may be related to pituitary-adrenal hyperactivity after trauma or an operation and that the venous thrombosis is a localized manifestation of this generalized hypercoagulability state. The nidus for the thrombus may be formed at the height of the stress period, although the deep venous thrombosis may not manifest itself until several days later when the nidus has resulted in sufficient thrombus formation to occlude a long segment of vein and its collateral channels. Stasis and intimal damage, when present, would enhance the development of the nidus.

Site, Symptoms, and Findings in Deep Venous Thrombosis

Site.—Originally, deep venous thrombosis was considered to occur principally in the calf veins.[2] Recent anatomic studies[3] and clinical experience[4]

From the Department of Surgery, Duke University School of Medicine.

Read before the Section on Surgery, General and Abdominal, at the 107th Annual Meeting of the American Medical Association, San Francisco, June 27, 1958.

suggest that the majority of deep venous thromboses involve the pelvic and iliac veins and that most pulmonary emboli originate in these larger vessels.

Our follow-up studies show that patients who originally had deep venous thrombosis of one leg only frequently displayed evidence of moderate postphlebitic venous insufficiency in the contralateral normal and uninvolved leg. This suggests that extensive venous thrombosis may be present without signs or symptoms.

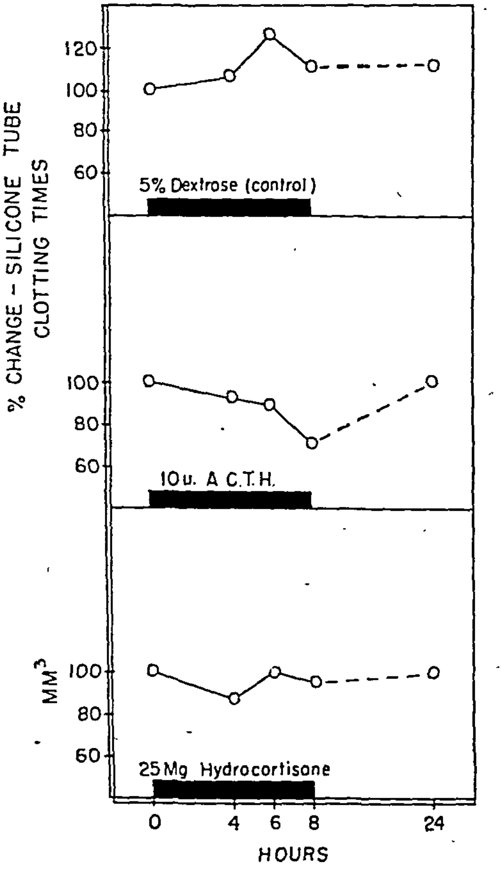

Fig. 1.—Effect of intravenously given ACTH and hydrocortisone on silicone tube clotting times, measured in percentage of change, in anesthetized dog; 5% dextrose in water was given intravenously to control animals.

Symptoms.—The signs and symptoms of deep venous thrombosis may be equivocal or quite definite depending on the severity of the process. Some patients may be asymptomatic, and others may complain only of pain along the course of the deep veins, without any objective findings. In such patients, the physician must rely on clinical experience as well as the intensity of the pain to decide whether a tentative diagnosis of deep venous thrombosis, warranting aggressive therapy, is justified. On the other hand, complaints of milder pain may lead the physician to careful observation of the patient for evidence of progressive deep venous thrombosis.

Objective Findings.—Signs which may be helpful in the diagnosis of deep venous thrombosis include (1) edema, varying from mild swelling at the ankle to massive swelling of the entire extremity; (2) distended pretibial and pedal veins, which in some cases may remain distended even with elevation of the foot above the level of the heart in the supine position; (3) presence of Homans' sign and positive findings on the Lowenberg test, which, however, may yield false-positive results in other inflammatory conditions of the structures in the calf of the leg; and (4) localized tenderness over the femoral vein in the groin, which is somewhat more specific than the Homans' sign, since fingerpoint pressure on other aspects of the thigh do not yield the same localized tenderness.

In patients who have been operated on, the legs should be routinely inspected at least twice daily for asymptomatic swelling. It has been of interest that in 12 paraplegic patients asymptomatic unilateral swelling of the leg (usually the left leg) was the only manifestation of deep venous thrombosis.

Pulmonary embolism without evidence of peripheral venous thrombosis occurred in 50% of 70 cases of embolism reported by us previously.[5] In some such cases the diagnosis of pulmonary embolism may be difficult to prove and to distinguish from other postoperative pulmonary complications; the physician will have to depend on his experience for the over-all evaluation of the patient prior to embarking on a regimen of therapy directed toward obviating further embolism.

Phlegmasia cerulea dolens, a manifestation of massive venous thrombosis with secondary arterial spasm, may be confused with primary acute arterial occlusion. This was noted in 19 of our patients and has been described in detail previously.[6] The following salient features should be noted in differentiating this syndrome from primary arterial occlusion: 1. The swollen limb. This indicates that the arterial inflow exceeds the venous outflow. Swelling does not occur in acute arterial occlusion.

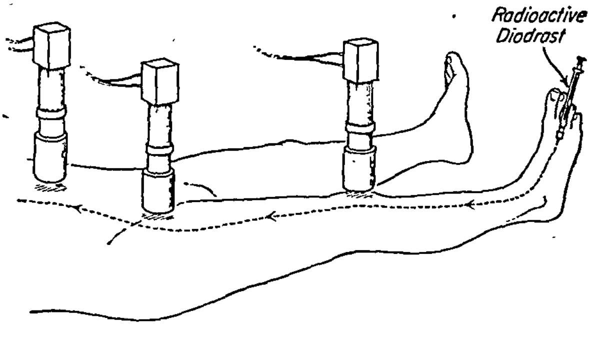

Fig. 2.—Arrangement of counters in patients undergoing venous outflow studies. Radioactive iodopyracet, 10-15 μc, is injected intravenously in the dorsalis pedis vein; radioactivity is measured at popliteal, saphenofemoral, and inferior vena cava stations.

2. Patchy blue discoloration of the skin. This is due to increased amounts of reduced hemoglobin in the extremity. In primary arterial occlusion the limb is generally white. 3. Prominent and distended superficial veins. With the massive venous thrombosis of the deep system, there is congestion of the venous circuit. In acute arterial occlusion the superficial veins are generally collapsed. 4. No definite sensory loss. There is no loss of sensation in the same segmental level as in primary arterial occlusion. Any sensory deficit is patchy and not of the "stocking-glove" type. 5. Presence of weak arterial pulses. The arteries in spasm may be faintly palpable all the way down to the pedal vessels, whereas in primary acute arterial occlusion the pulses are generally absent. 6. Dissociation between levels of coolness and lowest palpable pulse. Whereas in acute arterial occlusion there is a definite correlation between the lowest palpable pulse and the level of coolness, no such correlation is prevalent in arterial spasm complicating deep venous thrombosis. For example, the limb may be cool up to the groin in arteriolar spasm, and yet there may be a fairly good femoral pulsation. 7. An accessory consideration may be the absence of underlying heart disease as the etiological factor in the source of primary arterial embolus.

Laboratory Tests Aiding in Diagnosis of Venous Thrombosis.—Until recently, there were no laboratory tests to aid in the diagnosis of venous thromboembolism. Two possible approaches to this problem have been under investigation in our laboratory.

Isotope Outflow Studies: The isotope outflow test was described in a recent report.[7] Ten to 15 μc in 0.5 ml. of iodopyracet (Diodrast) tagged with radioactive iodine (I^{131}) is injected into the dorsalis pedis vein with simultaneously recording counters over the popliteal vein, the femoral vein, and the vena cava (fig. 2). The appearance time of the isotope and the shape of the curve of increase in radioactivity at each station is compared with the opposite leg and with normal controls. In deep venous occlusive disease a definite delay in the appearance of the isotope at each station occurs. Instead of a sharp wave of radioactivity, as noted in normal extremities (fig. 3), a slow jagged irregular rise in radioactivity develops (fig. 4). Unlike I^{131}-tagged serum albumin, I^{131}-tagged iodopyracet is excreted rapidly, and the small amount used (0.5 cc.) for each injection has been found free of any ill-effects.

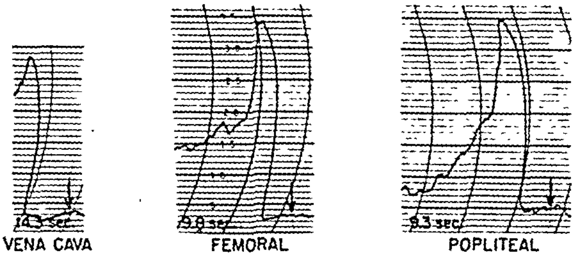

Fig. 3.—Venous outflow tracings in patient with lupus erythematosus and skin ulcers on right leg but normal deep venous system. Interval between injection and rise is short; rise is clear-cut, and return to base line is rapid.

Studies in 5-Hydroxyindoleacetic Acid Excretion: Platelets contain serotonin, and it is assumed that platelets break down during the process of thrombosis releasing their serotonin. The serotonin is excreted as 5-hydroxyindoleacetic acid (5-HIAA) (fig. 5). In 10 dogs massive intravenous thrombosis was produced by the intravenous injection of thrombin. The significant rise in urinary 5-HIAA, as depicted in figure 6, is in contrast to that observed in the control dogs, who received isotonic sodium chloride solution without thrombin and in whom no significant change in urinary 5-HIAA levels occurred. The urinary 5-HIAA levels of patients with thromboembolic disease is the subject of a study in progress at the present time.

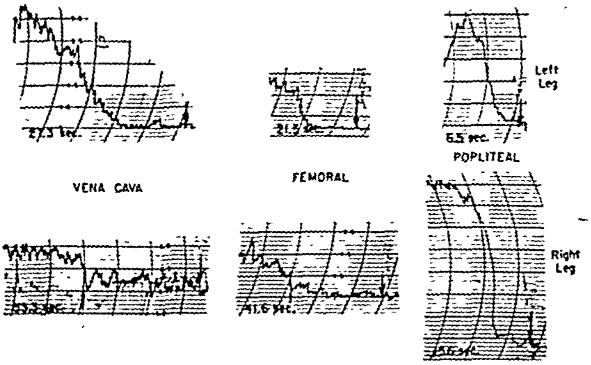

Fig. 4.—Delayed passage through postphlebitic deep venous system results in tracing with (1) prolonged interval between injection and rise, (2) irregular rise of curve, and (3) slow, irregular fall to normal.

Treatment

The object of treatment is twofold: (1) to avoid fatal pulmonary embolism and (2) to minimize postphlebitic sequalae. Patients with uncomplicated deep venous thrombosis without embolism are treated as follows: after base-line clotting time is obtained and a one-stage prothrombin test is done, the patient is started on heparin and coumarin drug therapy simultaneously. (After testing an array of coumarin drugs, we have returned to the use of bishydroxycoumarin [Dicumarol].) The heparin is administered as follows: 50-75 mg. of heparin given intravenously for an initial dose and 50 mg. of heparin given subcutaneously every four hours. The first subcutaneous dose is given at the same time as the intravenous dose. The clotting time is checked once a day thereafter at a time three and one-half hours after a given dose of heparin to ensure that the clotting time does not rise progressively to dangerous levels, as may occur after three or four days of heparin therapy. We prefer to have the clotting time (in the third tube of the Lee-White method) drop below 25 minutes at the three-and-one-half-hour checking point after the injection of heparin. If the clotting time at this point is above 25 minutes, the heparin dose should be reduced to 25 to 35 mg. every four to six hours.

It is also best to draw blood samples for the prothrombin test at the same time (three and one-half hours after the last dose of heparin) so as to minimize interference of the prothrombin test by the heparin. When the prothrombin level drops below 30% of normal, administration of heparin is discontinued and the patient is maintained on therapy with the coumarin drug for an average of eight days or until all swelling and symptoms of thrombosis have subsided and he is made ambulant.

Special Routines.—Following are suggestions for special treatment when the case is complicated by pulmonary embolism, a potential bleeding source, prostatic surgery, or pregnancy.

Pulmonary Embolism: Using the above routine of anticoagulant therapy, we have had a 15% recurrence rate of pulmonary embolism after the discontinuance of heparin therapy. Therefore, we suggest that patients with pulmonary embolism should be maintained on heparin therapy exclusively for eight days. The coumarin therapy is started at that time, and the heparin therapy is discontinued when the prothrombin level drops below 30% of normal. The coumarin therapy is maintained from 6 to 12 weeks with the patient on an ambulatory basis.

Potential Bleeding Source: Patients with a potential bleeding source, such as a duodenal ulcer, are safer on heparin therapy only, since effects can be reversed rapidly with protamine sulfate in the event of hemorrhage.

Prostatic Surgery: Patients who develop venous thromboembolism after prostatic surgery constitute a special problem, and the management of these has recently been reported by Galleher and one of us.[8] The use of half the usual dosage of heparin is advocated if the urinary catheter has been removed and the urinary drainage is clear of blood. Coumarin drugs are avoided. If the indwelling catheter is still in place and the urine is still bloody, it is safer to consider vena caval ligation, as will be discussed below.

Pregnancy: During pregnancy venous thromboembolism creates a very special problem, as discussed in detail by Parker and associates.[9] During the antepartum period before impending labor and during the postpartum period, the same plan of anticoagulant treatment is used as for uncomplicated deep venous thrombosis. During the intrapartum period in the patient with venous thrombosis, it is safer to delay anticoagulant therapy until the immediate puerperium. If embolization should occur just before or during labor, heparin may be administered by the intravenous drip method: 150 mg. of heparin in 1,000 cc. of 5% dextrose in water at 25 drops per minute over a 12-hour period.

Indications for Vena Caval Ligation.—Vena caval ligation was carried out in 23 patients for the following indications: (1) recurrent embolism despite multiple prolonged courses of anticoagulant therapy and (2) active bleeding coexisting with the development of venous thromboembolism, e. g., from prostatectomy.

This lifesaving operation is the last barrier to the development of pulmonary embolism. It is of interest that 1 of our 23 patients had a small but definite embolus one week after the vena caval ligation. The sequelae appear to be proportional to the degree of deep venous occlusion existing before ligation. Recently, in seven patients undergoing vena caval ligation, the venous pressures were monitored in both legs throughout the operation and the first few hours postoperatively; there was no rise in venous pressure resulting from the actual ligation in four of the seven patients, presumably due to previous adaptation to thrombotic occlusion of the iliac veins bilaterally.

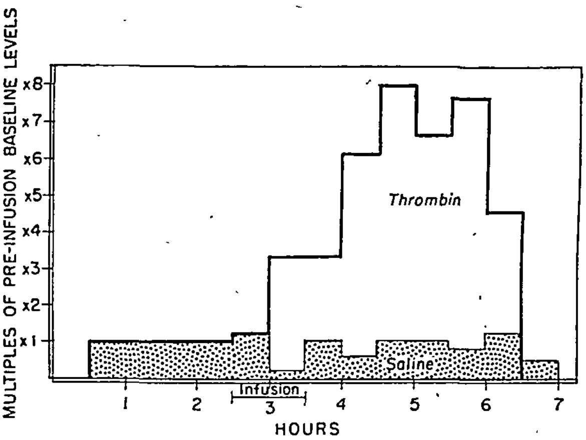

Fig. 6.—Urinary 5-HIAA excretion after intravenous infusion of thrombin and of isotonic sodium chloride solution in dogs.

Thrombectomy Combined with Anticoagulant Therapy.—We agree with Fontaine[10] and Mahorner and co-workers[11] that in massive venous thrombosis, particularly in younger individuals, thrombectomy should be considered through a venotomy in the common or superficial femoral veins. We prefer to start the heparin therapy preoperatively and to maintain this throughout the operation and the postoperative period. Only long-term follow-up studies of these selected patients will disclose whether thrombectomy combined with anticoagulant therapy is superior to anticoagulant therapy alone.

Femoral vein ligations have no place in the therapeutic armamentarium for venous thromboembolism. Unlike vena caval ligation, this procedure does not offer any safeguard from subsequent pulmonary embolism.[4] As described above, when anticoagulants are ineffective or contraindicated the site for venous ligation is the vena cava just below the renal vessels.

Prognosis

Of our 500 patients, 170 had primary acute deep venous thrombosis treated with anticoagulant drugs and followed for three or more years. We were able to evaluate 150 of the 170 patients for postphlebitic sequelae after intensive treatment with anticoagulant drugs during their acute phase. The results were as follows: no sequelae—leading normal life, 55.0%; wearing elastic supports full or part time, 19.0%; slight to moderate edema, 12.6%; dermatitis, 13.5%; incompetent superficial veins, 8.6%; and ulceration, 2.3%.

As mentioned above, it was of interest that in some patients postphlebitic sequelae were noted in the opposite normal limb that had appeared to be free of deep venous thrombosis at the time of initial treatment. Thus, in unilateral disease the uninvolved limb should be managed with equal concern.

In contrast to the 2.3% incidence of ulceration in our series, Bauer[12] reported a 20% five-year incidence in untreated patients. These results with anticoagulant therapy would support the opinion of de Takats[13] that vigorous treatment with heparin and elevation tend to minimize postphlebitic sequelae.

Summary and Conclusions

Venous thromboembolism remains one of the major hazards after surgical operations, trauma, or parturition. A hypercoagulability state appears to be the basic etiological factor; this may be aggravated by intimal damage and venous stasis. Symptomatology may vary from none to a combination of pain, swelling, venous distention, and pulmonary embolism. In the syndrome of arterial spasm complicating deep venous thrombosis (phlegmasia cerulea dolens), salient features differentiate it from primary acute arterial occlusion.

Two laboratory tests aiding in the diagnosis of venous thrombosis have been developed for use in patients with borderline symptomatology. The first is the isotope outflow study for the detection of venous stasis. The second is the detection of the serotonin breakdown product (5-hydroxyindoleacetic acid) in the urine in increased amounts in intravascular thrombosis.

Anticoagulant therapy is the treatment of choice. In pulmonary embolism an eight-day course of heparin therapy followed by several weeks of coumarin therapy is advised to obviate recurrent embolism. Vena caval ligation is indicated when coexistent bleeding exists or when there is recurrent embolism despite anticoagulant therapy. The use of thrombectomy combined with anticoagulant therapy in patients with massive venous thrombosis is still being evaluated.

Analysis of the long-term sequelae of patients who had primary acute deep venous thrombosis treated with anticoagulant drugs revealed no sequelae in 55.0% and ulceration in only 2.3%, as compared to other untreated patients in whom ulcerations were noted in 20%.

SUPRACONDYLAR FRACTURES OF THE HUMERUS IN CHILDREN

COMPLICATIONS AND PROBLEMS ASSOCIATED WITH TRACTION TREATMENT

O. Sherwin Staples, M.D., Hanover, N. H.

The supracondylar fracture of the humerus is the most common and the most likely, when badly displaced, to be accompanied by vascular injury. For the more severe injuries, traction usually provides the best opportunity to observe the arm closely, control swelling, and gently effect reduction and fixation of the fracture, and it is preferable to elevation and delayed manipulation. With one exception, patients in this study treated by traction recovered normal or almost normal function without significant deformity. While traction treatment has an important place in management, there is no one single method which can be universally applied as treatment for the badly displaced supracondylar fracture of childhood. In these severe injuries, there must be careful selection of treatment and constant vigilance, no matter what type of treatment is used.

The fracture of the distal humerus with circulatory impairment of the arm remains one of the most difficult of the fracture problems of childhood. Of the various types encountered, the supracondylar fracture of the humerus is the most common and the most likely, when badly displaced, to be accompanied by vascular injury. At the Hitchcock Hospital in Hanover, N. H., for 10 years we ordinarily have used traction methods for displaced supracondylar fractures of the humerus in children if there is more than moderate swelling and if there is any impairment of arm circulation. Manipulative reduction and cast fixation has been reserved for patients with no severe swelling and in whom normal circulation is maintained when the fracture is reduced and held in a position of 120 degrees of elbow flexion. We agree with the advocates[1] of traction for the more severe injuries that this method usually provides the best opportunity to observe the arm closely, control swelling, and gently effect reduction and fixation of the fracture and that it is preferable to elevation and delayed manipulation as used by us in the past.

The type of traction ordinarily used at the Hitchcock Hospital is essentially that described by Smith[1a] in 1947 and Hammond[1b] in 1949 and attributed to Böhler and Zeno. The apparatus includes a small-caliber Kirshner wire placed transversely through the olecranon, threaded, to prevent side slip, to which is attached a weight by spreader, rope, and pulleys. The hand should be held over the face, as this position ordinarily matches the distal and proximal fragments in point of rotation. The forearm is suspended by a sling, preferably off the horizontal, to elevate the hand. Later, after the swelling is reduced, a horizontal traction sling may be added, if necessary, to correct anterior position of the proximal fragment. Occasionally gentle manipulation in traction is required. With smaller children, a binder pinned to the mattress is usually necessary to prevent overactivity in bed. The wire is removed and a cast is applied when there is early union of the fracture, usually after three weeks. Lateral traction, the other type commonly used for these injuries (originally described by Dunlop[1c]), was used by us on only one occasion.

In a period of 11 years (1946 through 1957) 86 children, aged 1 to 14 years, with supracondylar fractures of the humerus have been seen at the Hitchcock Hospital. Thirty-seven of these had little or no displacement and required only cast fixation. Of the others, 17 were treated by manipulation and splint fixation and 31 by traction with or without open operation. In the group of patients treated by traction, almost half came to us after manipulative treatment had been tried unsuccessfully elsewhere and often after one or more days' delay. One of these patients, arriving 48 hours after injury with severe vascular injury and with fracture blebs covering elbow and forearm, went on to develop contracture due to ischemia (Volkmann's contracture). With this one exception, patients treated by traction recovered normal or almost normal function without significant deformity, although a result study at the end of the growth period is not available.

Among the 31 patients treated by traction at the Hitchcock Hospital were 7 in whom traction alone was ineffective or in whom complications developed. For purposes of discussion these seven problem cases can be divided into four groups, not including the patient already mentioned who arrived late with irreversible soft tissue damage. In comparison with other reports of experiences with traction treat-

---

Read before the Section on Orthopedic Surgery at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

ment for supracondylar fractures, the number is unusually large. Since this experience includes some problems and some errors not emphasized by others, a description of the complications that occurred might be of interest and value.

Complications

Distraction Resulting in Neurovascular Complications.—Two of the seven patients in whom problems were encountered exhibited distraction in the course of treatment resulting in neurovascular complications.

Case 1.—A 10-year-old boy was admitted to our hospital with an unreduced fracture seven days after injury. There was massive swelling of the arm. Fracture blebs covered the entire anterior surface of the elbow, and there was a complete radial nerve paralysis. The radial pulse was weakly palpable; the circulation of the hand was essentially normal.

Overhead traction of 8 lb. was applied, and all went well for two days. After 24 hours, roentgenograms (fig. 1) showed continued overriding of the fragments, but after 48 hours (fig. 2), and with no increase in weight, distraction was seen, and at this time the patient's pain, minimal before, became severe. The circulation of the hand was poor with loss of radial pulse. There was anesthesia of the hand, wrist, and forearm, and he was unable to move his fingers. At this point, and some three hours from the onset of any symptoms, traction was reduced to 3 lb. Three hours later the color and warmth of the hand improved to its previous status. Less than perfect position by x-ray was accepted, and the traction was maintained until early healing was obvious 17 days later. The anesthesia of the hand and forearm began to improve a few days after this neurovascular episode, and full recovery, including motor function, took place during eight months (fig. 3). Fifteen months after injury, except for a 5-degree loss of flexion, the arm was completely normal.

Case 2.—The second patient illustrating the same danger was a 4-year-old boy who had injured his elbow five hours before arrival. When he was first seen there was marked deformity, moderately severe swelling, a weak radial pulse, and normal circulation of the hand. Nerve function was intact. Overhead traction of 6 lb. was applied. Again, all went well during the first 24 hours, and, since check roentgenograms showed continued displacement, the traction was increased to 7 lb. Five hours later the patient complained of pain and, when examined soon afterward, was unable to extend his fingers actively. There was anesthesia of the hand, the radial pulse was not palpable, and the hand was cool and dusky. Traction was reduced to 6 lb. and on the next day to 4 lb. On the day after this episode, the radial pulse again became palpable, though it remained weaker than on the well side for a week. Traction treatment was continued for three weeks.

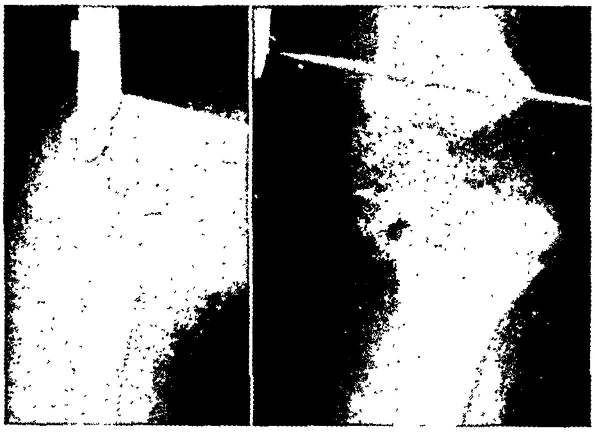

Fig. 1 (case 1).—Initial roentgenogram showing arm in traction, with overriding of fragments, after 24 hours.

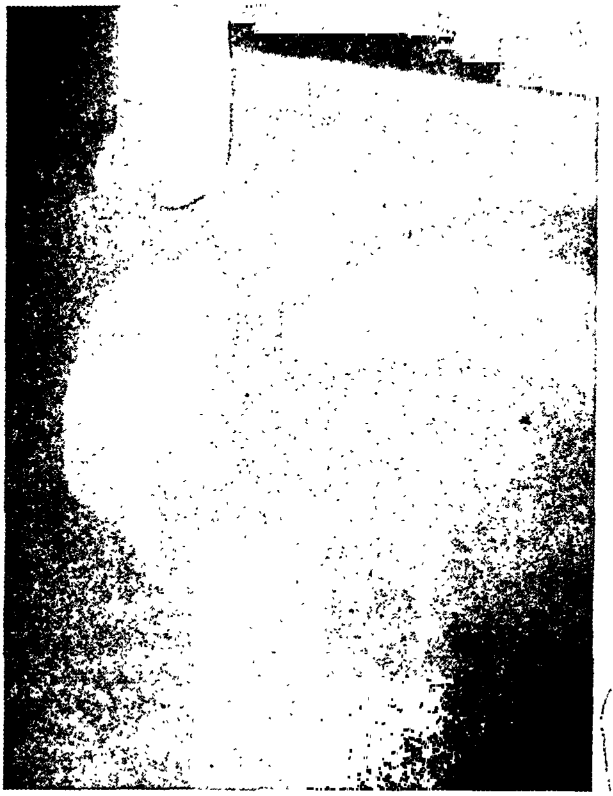

Fig. 2 (case 1).—Roentgenogram showing distraction present after arm had been 48 hours in traction.

Sensory and motor function began to return some three weeks after the injury and was almost normal in seven months. Ten months after injury there was full motion of the extremity, and except for slight coolness of the affected hand and slight intrinsic hand weakness a completely normal upper extremity was found.

Whether these complications represent ischemic neuropathy or a combination of nerve and vessel injury does not seem to be of as much importance as the fact that they occurred during traction treatment and should be avoided. Distraction is an obvious fault but one which we did not avoid on these two occasions, even though the amount of weight used did not, at the time, seem excessive. These experiences make us feel strongly that, first, prompt reduction in 24 or 48 hours should not be the rule; second, initially enough weight should be used only to suspend the arm; and, third, any complaint of increasing elbow pain should receive prompt attention. We now seldom use more than 4 lb. at first. This is somewhat at variance with other reports which do not stress this matter, but we do eel that one should start with a small weight and, uided by the status of swelling and circulation, ncrease the weight slowly and gradually during everal days regardless of the duration of the fracure. As shown in these two patients, a minor degree of overriding is consistent with a good result rovided reasonably good alignment is present.

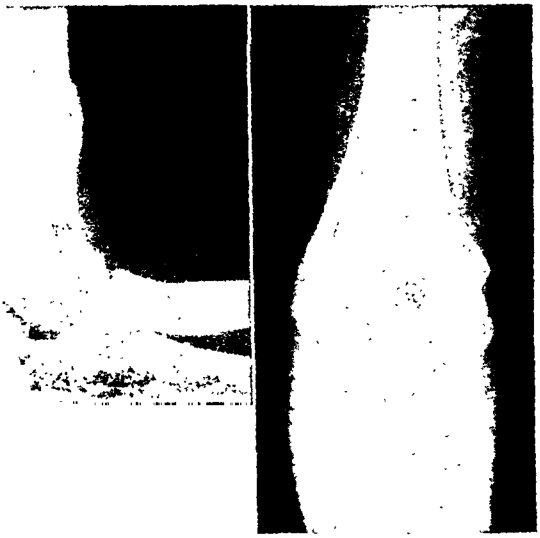

Fig. 3 (case 1).—Roentgenogram taken six months after injury to arm.

Displacement of Brachial Artery Preventing Traction Treatment.—Occasionally the injury may be such as to displace the brachial artery so that traction treatment alone cannot be safely used. Such patients, of whom we had two, should be recognized and treated promptly.

Case 3.—A 5-year-old boy arrived untreated two hours after injury. The elbow was markedly swollen and held in 30 degrees of flexion. The radial pulse and skin circulation were normal. There was no nerve involvement. After the anesthetic had been given we were surprised to find that flexion of the fractured elbow (fig. 4) to 45 degrees or even long axis traction of the extremity produced obliteration of the radial pulse and complete loss of circulation to the hand. Happily, by restoring the arm to its original position, the circulation soon became normal.

Exploration of the brachial artery was carried out immediately through a longitudinal incision, S-shaped to diminish scar contracture. The artery was found to have slipped behind the median epicondyle so that it actually ran between the two fragments of the humerus (fig. 5). The artery, undamaged, was restored to its proper location. The fracture was reduced by manipulation, and the skin only was closed, leaving the fascia open. The arm was fixed first in a cast and later by overhead traction. Uneventful recovery followed, and on examination four years later there was full function and no deformity.

Case 4.—A 4-year-old girl entered the hospital with a widely displaced supracondylar fracture three hours after injury. There was marked swelling, a palpable radial pulse, and normal hand circulation. There was no obvious nerve damage. With the patient under anesthesia it was found that elbow flexion to 50 degrees produced immediate loss of both radial pulse and of circulation in the hand. After two attempts the position of overhead traction could be maintained without loss of pulse or of circulation to the hand. This was maintained by 5 lb. of Kirshner wire overhead traction. The swelling decreased, and, because of persistent displacement and overriding of the fracture, the weight was increased to 7 lb on the afternoon of the fifth day.

Although during the night routine three-hour checks by the nursing staff revealed no change, it was noted in the morning that the elbow was painful, the radial pulse was no longer palpable, and the hand was cool, with loss of sensory and motor power in the hand. The traction was reduced to 3 lb., and in a few hours the circulation again became normal. During 24 hours there was partial recovery of sensory and motor function.

Exploration of the brachial artery and median nerve was carried out two days later. Acute angulation of these structures over the distal tip of the proximal humeral fragment was found. The artery and nerve were freed, the fracture reduced, and a cast applied. The position was held and no further complications ensued. Thirteen months after injury, except for 5-degrees' loss of hyperextension, there was full motion, no deformity, and normal nerve and blood vessel function. In retrospect, it appears that this patient could have been better treated if the plan followed with the patient in case 3 had been used.

Persistent Angular Deformity Not Correctible by Traction or Manipulation.—There is general agreement that, although less than perfect position in the lateral roentgenograms can be accepted in the supracondylar fracture of childhood, yet any serious degree of rotatory or angular deformity, particularly in the frontal plane, must be corrected.[2] Open operation and internal cross wire fixation was necessary for one of our patients after failure of traction and manipulation to correct the deformity. At operation a small displaced central fragment was found to be the cause of the persistent deformity. Ten months after operation, except for a 10-degree loss of elbow flexion, the arm was normal. This is not an easy way to treat these fractures and, in our opinion, should be reserved for only those patients in whom traction and manipulation have failed.[3]

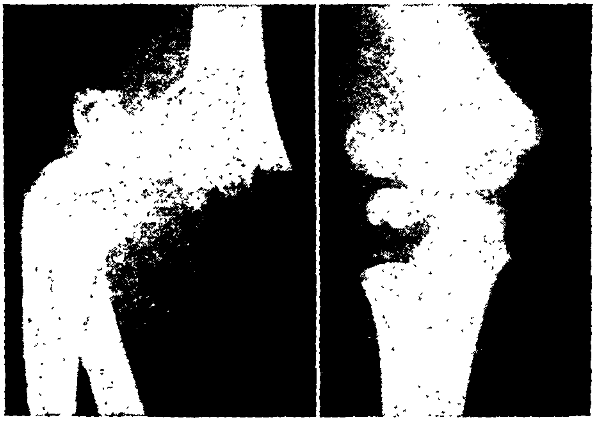

Fig. 4 (case 3).—Initial roentgenogram showing fracture of elbow.

Incipient Ischemic (Volkmann's) Paralysis.—We agree with Blount[4] that the absence of a radial pulse is not an indication for operation if the skin circulation of the hand is normal. We also agree that with inadequate arm and hand circulation, if prompt improvement does not follow simple measures such as gentle traction or procaine hydrochloride (Novocain) blocks of the stellate ganglion, exploration of the artery is required immediately. Although sometimes resection of a segment of the brachial artery is indicated because of persistent spasm or thrombosis,[5] such treatment was not required in any patient in our series.

We have had two patients with inadequate arm circulation due to marked brachial artery spasm. These patients, seen early and failing to respond to simpler measures, were treated successfully by exploration, fasciotomy, release of hematoma, and traction for reduction and fixation.

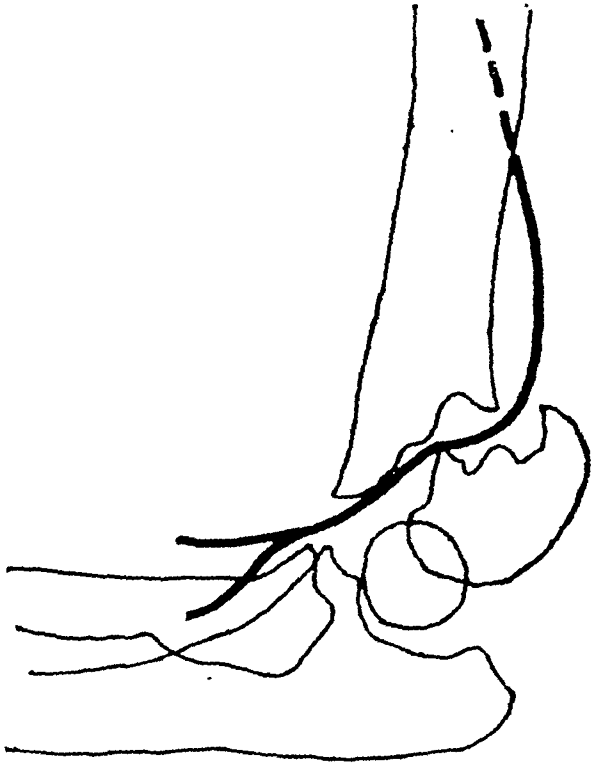

Fig. 5 (case 3).—Diagram showing operative finding of artery behind median epicondyle and between two fragments of humerus.

Case 5.—One of these two patients, a 5-year-old boy, had an interesting problem (fig. 6) in the postoperative period. After an operation for the relief of circulatory impairment, the patient was fixed in a cast in which the fracture slipped. After two days a Kirshner wire was inserted and the arm put in the overhead position. The radial pulse immediately disappeared, regardless of the amount of traction used. When the arm was held horizontal at the side with the elbow in 30 degrees flexion, the radial pulse again became palpable. We believe that this behavior was due to the fact that the distal end of the proximal humeral fragment had been widely stripped of soft tissue by injury and in the overhead position sagged anteriorly, producing brachial artery spasm. A modified Dunlop type traction was used, with a 3-lb. pull applied by Kirshner wire to the abducted, horizontal arm and with the forearm suspended in 35 degrees of elbow flexion by a 1-lb. adhesive traction (fig. 7). The further course was uneventful.

After considering the course of this last patient, one might infer that the Dunlop type traction is preferable. Our limited experience with this type of traction allows us to draw no conclusions. No matter which type of traction is used, it is clearly dangerous to assume a carefree attitude. Distraction undoubtedly is dangerous whether the arm is horizontal or vertical, and, if there is critical displacement of the brachial artery or persistent inadequate arm circulation, neither type would be safe.

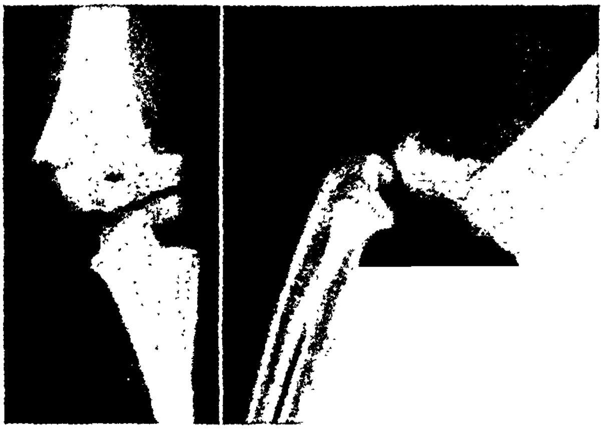

Fig. 6 (case 5).—Initial roentgenogram showing fracture of elbow.

Conclusions

No single method can be used as treatment for the badly displaced supracondylar fracture of childhood. Exemplified by our experience, there must be careful selection of treatment and constant vigilance, no matter what type of treatment is used. In spite of our problems we still feel that traction treatment has an important place in the management of these severe injuries.

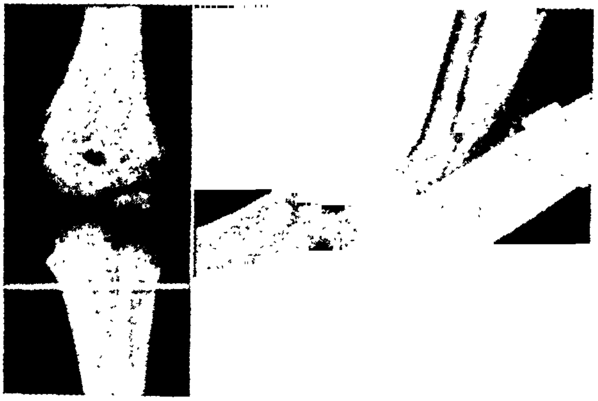

Fig. 7 (case 7).—Roentgenogram taken after application of horizontal traction.

REGIONAL ANESTHESIA—A REAPPRAISAL

John J. Bonica, M.D., Tacoma, Wash.

It is the purpose of this presentation to indicate the present status of regional anesthesia, to recount some of the recent developments and trends in this field, and to suggest its proper role in surgical, obstetric, and medical practice in the light of current concepts in anesthesiology. Although the discussion would seem hardly worthwhile in an era when the "magic mixtures" of muscle relaxants, intravenous barbiturates, and gaseous anesthetics dominate the scene in American anesthesiology, I believe it is a timely topic for reasons which will become apparent. A reevaluation of the method is particularly important in view of present trends in anesthesiology and the differences of opinion among anesthesiologists regarding regional anesthesia. It is especially important for surgeons, obstetricians, and other physicians who are not anesthesiologists to realize and appreciate the limitations, indications, advantages, and disadvantages of this method of anesthesia.

Recent Developments

During the past two decades many significant changes have been made in anesthesiology, both in concept and in clinical practice.[1] These changes have been due not only to the ever-changing patterns characteristic of medicine as a whole but to certain factors peculiar to anesthesiology itself. Of these the most important by far is the increase in the number of physicians who have entered this specialty since World War II, which demonstrated emphatically the need for trained anesthesiologists and precipitated the interest in this field.

The anesthesiologist should be equally skilled in all anesthetic methods, both general and regional. Regional anesthesia is remarkably flexible in application. Regional blocks of the extremities do not upset the systemic water-electrolyte balance, the blood chemistry, or the functions of kidney, liver, and heart. When used in situations to which it is adapted it causes the least possible disturbance of bodily functions. It affords complete muscular relaxation which is limited to the part involved. While balanced general anesthesia is superior to regional techniques in major operations on the head, neck, thorax, and upper abdominal cavity, regional anesthesia is particularly useful in operations on the lower abdomen, back, extremities, and superficial parts of the body and in obstetrics. It is assumed that the surgeon is experienced, skillful, and gentle and that he observes the basic principles of good surgical technique. To assure the patient of the best anesthetic care, both regional and general anesthetics must be available to the anesthesiologist, and he should be free to choose on the basis of their respective indications and limitations.

From the Department of Anesthesiology, Tacoma General Hospital, and Pierce County Hospital.

Read before the Section on Anesthesiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

The recent progress in surgery has further emphasized the urgent need for commensurate improvements in anesthetic care. The advent of ultraradical surgical invasion of certain organs, which before had been considered forbidden, prompted anesthesiologists to hazard procedures notable for the liberties taken with vital processes. These physiological trespasses, which concern total muscular paralysis, marked reduction of blood pressure and temperature, and asystole, are now considered to be justifiable risks which may be taken in order to make certain operations possible.

All these factors have prompted greater scientific activity, understanding, and achievement in this relatively new field. The trial and error methods have been replaced by well-directed laboratory and clinical research into respiratory, cardiovascular, and other physiological functions. There has ensued a remarkable augmentation of knowledge of the alterations anesthesia produces in them and of ways and means to minimize the effects. This knowledge, in turn, has prompted revisions of numerous concepts of anesthetic management and has resulted in the development of many new agents, techniques, and methods.

One of the outstanding developments, and the one which next to the advent of the anesthesiologist is the most significant, is the full appreciation by most seriously thinking surgeons, obstetricians, and anesthesiologists of the concept that the administrator is far more important than the drug, technique, or method being employed. Critical evaluation of various methods has reemphasized that in the hands of the skilled physician any method may be employed to the advantage of the patient. Differences in indications, advantages, disadvantages, and complications of various techniques have become significantly less important than before.

All of these factors have had a profound effect on the practice of regional anesthesia, and they indicate an obvious need for reassessment of the method in order to place it in proper perspective. The following opinions are based on experience gained by personal administration, supervision, and teaching of all methods of anesthesia during the past 15 years and by recent observations of practices carried out in many medical centers in the United States and abroad.

Current Trends in Regional Anesthesia

In recent years there has been a marked decrease in the use of regional anesthesia, particularly in surgery.[1] There are several reasons, but foremost is the high standard obtained in general anesthesia, making it more suitable for poor-risk patients. Formerly, if a trained anesthesiologist was not available, poor-risk patients were operated on under regional anesthesia administered by the surgeon, with untrained personnel or an anesthetist technician in attendance; now, in these circumstances, general anesthesia is administered.

In the excitement of knowing about and of taking part in the many developments in balanced anesthesia, anesthesiologists have neglected the regional technique. Teachers have justifiably emphasized the great importance of general anesthesia, but in doing so they have slighted regional techniques. As a result, many physicians have finished their training in anesthesiology with little or no experience with this method. In their practice they feel uncertain about it, and rather than risk a failure they use general anesthesia instead. This is unfortunate, indeed, because the well-trained anesthesiologist should be able to administer all forms of anesthesia equally well.

Drugs.—Despite these trends, there have been a number of new developments in regional anesthesia. One of the most significant of these has been the adoption of standardized methods of clinically evaluating local anesthetic drugs.[2] This development has been prompted by the realization that, while laboratory experimentation in animals is an essential prerequisite for development of a drug, the data obtained by such experiments can only be used as a crude yardstick and must be substantiated in clinical trials on human beings. This is particularly applicable to local anesthetic agents, since these are administered by several routes and by numerous techniques, which variations are accompanied by variations in therapeutic or toxic effects. The procedures now adopted include, among others, proper statistical design and standardization of the study prior to initiation of the clinical trial, the use of a standard of reference (procaine), and the use of unknowns (the "blind" technique). The essential characteristics of local anesthetic drugs which require clinical evaluation include potency, latency or the time of induction, penetrance and extension, duration, and toxicity. These characteristics must be studied with each of the regional anesthetic procedures carried out under standardized conditions.

Clinical evaluation under these conditions has revealed that the newer drugs, lidocaine (Xylocaine) hydrochloride, chloroprocaine (Nesacaine) hydrochloride, hexylcaine (Cyclaine) hydrochloride, and propoxycaine (Blockain) hydrochloride have certain advantages over procaine which warrant their clinical use.[3] Chloroprocaine is the most rapid-acting agent; lidocaine and hexylcaine are almost as rapid. Procaine, piperocaine (Metycaine) hydrochloride, and parethoxycaine (Intracaine) hydrochloride may be considered to have action of intermediate rapidity, and tetracaine (Pontocaine) hydrochloride and dibucaine (Nupercaine) hydrochloride are slow-acting. Concerning penetrance or ability to spread by penetrating fascial and other tissue barriers, lidocaine is the most effective, with chloroprocaine and hexylcaine second; procaine, tetracaine, piperocaine, parethoxycaine, and dibucaine have fair to poor penetrance. Concerning duration of action, procaine, chloroprocaine, and piperocaine may be considered as drugs of short duration (approximately one hour), parethoxycaine, hexylcaine, and lidocaine as drugs of intermediate duration (one and one-half to two hours), and tetracaine and dibucaine drugs of long duration (over two hours).

Another important development is the realization that in order to evaluate a local anesthetic drug it is necessary to consider the "corrected toxicity ratio" and not the absolute toxicity. In other words, if a certain drug is 10 times as toxic as the standard drug procaine (of which the relative toxicity ratio is 10) but can be employed in one-twentieth the dose of the standard drug (of which the relative potency ratio is 20) with equal effectiveness, then its toxicity is actually one-half that of the standard drug and the corrected toxicity ratio is 0.5 and the anesthetic index 2. Extensive clinical evaluation of various local anesthetic drugs with procaine does not bear out the often quoted statement that procaine is the least toxic of all anesthetic agents.[4] This misconception, which is based on animal experimentation in which toxicity was evaluated by one form of injection (usually the intravenous route) and potency by another (subcutaneous) has misled many clinicians into believing that procaine is innocuous. A number of other drugs, but particularly tetracaine and chloroprocaine, when employed in equal concentrations, produce significantly less incidence of toxic reactions than does procaine.[5] At the same time chloroprocaine affords the advantage of producing an analgesia which is much more rapid and tetracaine that of anesthesia of longer duration.

It is obvious that each of the local anesthetic drugs presently available for clinical use has desirable properties which may indicate it for a specific circumstance. It needs to be emphasized that there is no local anesthetic agent which is so superior to all the others as to warrant its exclusive use. Moreover, it is necessary that the clinician know the characteristic of each drug in order for him to be able to select the optimal drug in each circumstance. Thus, if it is desirable to have a drug with low toxicity, rapid onset, and short duration, chloroprocaine is the anesthetic of choice. If rapidity of onset is not important, tetracaine or dibucaine are by far the best agents. When properly employed (optimal concentration and optimal volume) tetracaine and dibucaine are no more toxic than most other local anesthetic drugs. The validity of this statement is obvious when one considers that tetracaine and dibucaine have been used for saddle block and other techniques or subarachnoid (spinal) block in millions of cases without significant neurological or other sequelae.

There has been a trend to abandon the use of hyaluronidase for enhancement of the spread of local anesthetic solution because results have been disappointing. Although this agent does hasten the onset of infiltration, topical, and extradural anesthesia, it does not so consistently increase the number of successful regional nerve blocks as had been hoped, and at the same time it markedly increases absorption with a consequent shortening of the duration of anesthesia and an increase of toxic reactions.

The use of Efocaine (an anesthetic mixture, with 1% procaine, 0.25% procaine hydrochloride, and 5% butyl-*p*-aminobenzoate in solution) has been abandoned in most clinics because of the serious neurological complications which have occurred after its injections. Oil solutions, long claimed to produce prolonged block, have been abandoned because of poor results and high incidence of inflammatory reaction, separation, and necrosis. Phenol and alcohol have been employed as neurolytic agents successfully to produce prolonged interruption, but their use is not without risk since it is frequently followed by neuralgic pain and other manifestations of chemical neuropathy.[4]

Techniques.—Since the advent of muscle relaxants, the use of spinal anesthesia, which formerly enjoyed an eminent status for surgery performed below the diaphragm, has declined considerably. A number of factors have been responsible for this decline: the surgeon no longer administers spinal anesthesia in the absence of trained personnel, and certain misconceptions concerning serious neurological sequelae have arisen. Since this method has been covered by another speaker, I will do no more than emphasize that when properly employed it constitutes one of the most practical and safest forms of anesthesia. Notwithstanding the misleading reports of (poorly conducted) clinical surveys which tend to show that the incidence of serious neurological complications is still frighteningly high, its safety has been definitely demonstrated by well-controlled studies.[5] These studies have revealed that complications attributable to the anesthesia were extremely rare after spinal anesthesia and that the mortality was significantly lower than that recorded after general anesthesia. The use of needles of smaller diameters and better drugs, the widespread adoption of dry heat and autoclaving to sterilize the spinal anesthetic agents, and general improvement in techniques have lowered the incidence of complications almost to a minimum. The safety of spinal anesthesia is further attested by its widespread adoption for the provision of relief of pain of childbirth in many millions of mothers without significant incidence of serious complications.[5d]

In the past several years there has been an increase in the use of spinal epidural blocks in America, probably as a result of the aforementioned unjustified resentment against spinal anesthesia and the desire of some physicians to find a suitable substitute for it. Since in this technique the dura is not punctured and the solutions are not injected directly into the subarachnoid space, headaches and cranial nerve palsies do not occur and the hazards of neurological sequelae theoretically do not exist. Moreover, in some instances a limited segmental block of the lower thoracic and lumbar regions suffices, so that the undesirable cardiovascular and respiratory effects are less and postanesthetic dysfunction of the bladder, rectum, and lower extremity is avoided.[6]

Since epidural block requires only one puncture, it has significant advantages over multiple intercostal, paravertebral, and peripheral nerve blocks. It is also preferred to extensive local infiltration or field blocks because it provides more complete analgesia and muscular relaxation and requires less anesthetic drug, does not distort tissues, and does not interfere with the postoperative repair. The potency, penetrance, and rapid action of chloroprocaine, lidocaine, and hexylcaine have minimized such disadvantages of extradural block as slow onset and inadequate relaxation, and their use has therefore become widespread. The feasibility of placing an indwelling catheter into the extradural space has further extended the clinical utility of this technique and has augmented its superiority over other regional techniques which require multiple punctures. The continuous technique not only affords much better control of duration, intensity, and extent of block but permits the continuation of analgesia into the postoperative period for relief of severe pain. The fact that the catheter does not come into contact with nerve elements and that the danger of exposing them to the constant irritation of a foreign body is eliminated constitutes a significant advantage of this technique over that of continuous spinal anesthesia.

On the other hand, epidural block is more difficult to carry out, and there is consequently a greater incidence of failure than with spinal anesthesia. Notwithstanding these disadvantages, it can be stated that epidural block in certain circumstances where a segmental block is adequate, such as chordotomy or inguinal and femoral herniorrhaphy, offers advantages to the patient and surgeon. Peridural analgesia is also useful in the control of the pain of the first stage of labor and in the provision of anesthesia for vaginal or abdominal delivery. But the greatest use of this technique is as a diagnostic-therapeutic tool in the management of various medical disorders.[6]

The use of single-dose and "continuous" caudal anesthesia in obstetrics has steadily increased, while for surgery it has decreased. The trend in surgery is due to the increasing use of general anesthesia and spinal epidural block.

Peripheral nerve blocks, including block of the brachial plexus, sciatic, and femoral nerves, have been used less, as have all other regional techniques, since the advent of muscle relaxants and intravenously given barbiturates. However, the decrease has not been as great as with some other techniques, because the value of regional anesthesia for the surgery of extremities is recognized.

Paravertebral blocks, which were formerly used in combination with light general anesthesia in poor-risk patients undergoing neck, thoracic, or abdominal surgery, have been almost completely abandoned. This has been due to improvement in general anesthesia, more frequent use of segmental epidural block, and a greater appreciation of the complications (hypotension and pneumothorax) and hazards (total spinal anesthesia) inherent in paravertebral blocks, especially in the thoracic region. The high incidence of these complications has also discouraged the use of this technique as a diagnostic and therapeutic procedure.

The advantages of field block or local infiltration for minor surgery are still appreciated and account for the widespread use of these techniques in general practice. Cranial nerve blocks for surgery were never very popular, and at the present time they are rarely performed, except in unusual circumstances.

There have been very few changes in the clinical use of topical anesthesia, which continues to be widespread for various endoscopic procedures and operations on the mucous membranes in the body. A number of new topical anesthetic agents have been employed extensively because of specific advantages. These include lidocaine and hexylcaine, which have a rapid and profound action.

Applications of Regional Anesthesia—Reappraisal

In considering the clinical application of any method of anesthesia and evaluating its proper role, it is essential to remember certain premises and precepts. The most fundamental of these is that the desired effects in anesthesia are always obtained at a price exacted from the patient in the form of physiological deviations or depletions. It is the primary mission of the anesthesiologist to select indicated agents and techniques and employ them in such a manner as to cause the least degree of disturbance to bodily functions. How effectively he discharges such a grave responsibility depends primarily on his judgment, skill, and experience. It bears reemphasis that the agent or technique is of secondary importance to the administrator. On the other hand, it is also true that, in the hands of one equally skilled with all anesthetic methods, in certain circumstances there is one method which is superior to all others.

These are fundamental principles of the modern practice of anesthesia which are well known but, unfortunately, are frequently neglected, especially in the consideration of regional anesthesia. The nonspecific manner with which some writers have attempted to evaluate this method is one of the most notable factors which have contributed to improper application, poor results, and consequent disuse. It has often been stated without qualification that regional anesthesia disturbs the physiology of patients much less than general anesthesia, as if this rule applied to all circumstances regardless of the patient's condition, the extent of the anesthesia required, and the type and magnitude of the operation. I believe this is a fallacious approach for the evaluation of any method, but particularly of regional anesthesia, because its flexibility of application and diversibility of effects prohibit generalities concerning its clinical use.

In the following discussion, it is assumed that the anesthesiologist is equally competent in administering general and regional anesthesia. Moreover, it is assumed that the surgeon has the necessary experience, exercises skill and gentleness, and observes other basic principles of good surgical technique. Certainly, regional anesthesia should not be considered if these conditions do not exist. Moreover, the patient's age and physical status should be considered. Regional anesthesia may be employed to advantage in infants and children provided they are psychologically prepared and given proper medication. Elderly patients are good candidates provided the technique does not entail extensive vasomotor paralysis. It is mandatory that candidates for this or other forms of anesthesia be selected with the greatest care, that they be so prepared that they are in optimal psychological and physiological condition, and that the procedure be carried out with a degree of skill that comes only with mature experience.

Regional Anesthesia for Operations in the Head and Neck.—Improvements in intravenous and inhalation anesthesia and the widespread use of the endotracheal tube have obviated much of the need for regional anesthesia for major operations of the head and neck. General anesthesia spares the patient the psychological stress peculiar to major operations in this region; the use of the endotracheal tube assures him a patent airway; and the anesthesiologist, while still keeping away from the field of operation, has better control of the patient. These considerations are particularly important in most intracranial operations and extensive procedures of the face, nose and paranasal sinus, mouth, and throat. Because of multiple innervations of many of these structures, such operations often require block of several nerves which are deeply located near vital structures, thus making regional anesthesia much more time consuming, more difficult, and more hazardous than general anesthesia.

There are a number of clinical applications for local and regional anesthesia worthy of consideration. Lacerations of the scalp and simple depressed fractures in the presence of probable intracranial damage are best managed by the regional method. The value and necessity of regional anesthesia for craniotomy in patients in whom it is necessary to localize lesions prior to the excision of the cerebral cortex for epilepsy is well established. In posttraumatic operations on the face, maxilla, and throat, it may be advantageous to have the patient awake with an active laryngeal and swallowing reflex. Such is the case in simple fractures of the jaw which require wiring, in tracheotomy for supraglottic obstruction, and in helping to demonstrate an esophageal diverticulum. Many surgeons still prefer the patient to be awake and talking in order to help detect damage to the recurrent laryngeal nerve during thyroidectomy and other operations on the neck.

Because of the advantages they afford the patients, local infiltration and topical anesthesia have maintained their primary position for many operations on the eye and for the simpler procedures involving the nose and contiguous structures. Infiltration anesthesia remains the method of choice for tonsillectomy in adults. Most small lesions on the tongue, lip, and face are still being removed and numerous plastic operations are being performed with local, field, or nerve block. Simple operations of the neck may be performed with bilateral cervical plexus block.

Regional Anesthesia for Operations in the Extremities.—Regional anesthesia has its greatest usefulness in surgery for patients who require operation of the extremities because it affords more significant advantages for this purpose than for any other surgical application. This is particularly true of brachial plexus block for surgery of the upper extremity and sciatic-femoral block for the lower extremities. It is also true of blocks of median, ulnar, and radial nerves at elbow or wrist and of block of the peroneal or tibial nerves at knee or ankle. When properly administered and effective for the duration of the operation, these techniques provide conditions which cannot be matched by any other form of anesthesia. The outstanding advantage is that they tax the physiological economy of the patient less than does general anesthesia, since they involve only a limited area and do not interfere with the function of other organs or structures.

By producing a transient "physiological section" of the nerves supplying the involved extremity, these techniques effect specific and complete sensory blockade and thus protect the central nervous system against noxious impulses that may have deleterious effects. That such is not the case with general anesthesia has been shown by electroencephalographic studies, which indicate that afferent impulses continue to reach the central nervous system even when the patient is in deep general anesthesia.[7]

If muscular relaxation is necessary, complete paralysis may be effected, but, unlike that produced by deep general anesthesia or muscle relaxants, it is limited to the extremity and does not interfere with muscles of respiration. This precludes the need for controlled or assisted respiration and obviates the consequent cardiovascular disturbances. The concomitant sympathetic block may prove of value in some patients.

Regional blocks of the extremities do not affect electrolytes, fluids, blood chemistry, or the functions of the kidney, liver, or other parenchymatous organs, nor do they depress the myocardium and peripheral vascular bed as do barbiturates and most inhalation agents even when administered properly.[1a] These considerations are important in any patient, but particularly in the so-called poor-risk patient, who may not tolerate the stress imposed by general anesthesia. Patients who present complicating conditions, such as shock, cardiac, pulmonary, hepatic, and renal diseases, diabetes, cerebrovascular disorders, and chest and head injuries, are usually able to withstand the necessary surgery of the extremities with regional block better than with narcosis. Clinical studies have demonstrated that mortality and morbidity after regional anesthesia are considerably less than after general anesthesia.[8]

The method under discussion is particularly applicable in older patients and in urgent situations when little is known about the patient or when it is necessary to operate on a patient with a stomach full of undigested food. Whenever fluoroscopy or x-ray is a necessary adjunct to the surgical procedure, regional anesthesia eliminates the danger of explosions, respiratory depression, or obstruction in the darkened room and the patient is able to cooperate with the surgeon.

One of the most significant advantages of regional anesthesia of the extremities is the minimal postanesthetic nausea and vomiting and the immediate postoperative analgesia made possible by the use of one of the longer-acting local anesthetic agents, such as tetracaine. The accompanying sympathetic block during this period may prove of value in the prevention or minimization of postoperative reflex sympathetic dystrophy. All these factors permit earlier ambulation and oral feeding and consequently decrease the incidence of postoperative pulmonary, gastrointestinal, and thromboembolic complications.

The disadvantages of regional anesthesia are the slightly slower onset of action, failures in providing complete anesthesia, and complications which occasionally occur. Chloroprocaine, lidocaine, and hexylcaine, because of their rapid action and superior penetrating powers, have decreased the first two disadvantages, but they still exist. With experience and care complications should be minimal. Pneumothorax occurs with brachial block, while postblock neuropathy occurs only if the nerves are injured and if high concentrations of the anesthetic are used.

It hardly needs to be emphasized that the significance of these advantages and disadvantages depends primarily on the ability of the anesthesiologist. For example, there is little doubt that a brachial plexus block skillfully administered to an elderly patient with emphysema who is to have a complex reconstructive operation of the hand which will take several hours provides advantages which cannot be duplicated by any method of general anesthesia. On the other hand, the same procedure improperly performed by one who is quite or relatively unacquainted with the technique and who misses the target, thereby producing inadequate analgesia and puncture of the apex of the lung, will cause far more harm to the patient than several hours of deep general anesthesia.

Extradural block, effected either via the sacrococcygeal hiatus (caudal anesthesia) or by the spinal epidural route, provides, as previously mentioned, the advantages of peripheral nerve block and of subarachnoid block without most of their disadvantages. The continuous technique may be employed to produce sympathetic block and relief of pain during the preoperative and postoperative periods, as well as surgical anesthesia in patients with vascular disorders (embolism) or severe trauma.[4b] Single-dose or fractional subarachnoid block anesthesia limited to the lumbar and sacral segments is, of course, simpler to execute and produces more rapid anesthesia than epidural anesthesia. It is the most common regional technique employed for surgery of the lower extremity.

Operations on the Chest.—Minor operations involving the breast or other structures of the chest wall may be best performed with regional anesthesia, especially in aged or seriously ill patients. This method is also preferable when the patient is to be prone or in any other operative position that makes the use of an endotracheal tube necessary. In such cases, field block or intercostal block or both, if completely adequate for operation, are preferable to segmental epidural or subarachnoid block. Regional anesthesia, usually in the form of paravertebral-brachial plexus-infiltration block, is still the favorite method for thoracoplasty in many thoracic surgical centers.[1b]

During the past decade, numerous writers have described and advocated various regional anesthesia techniques, high and segmental subarachnoid block and segmental epidural block, in particular, as the primary method of anesthesia for thoracoplasty, pulmonary surgery, and other intrathoracic operations.[9] Among the advantages of regional anesthesia cited by most of its advocates are the facts that the risk of explosion is eliminated, bleeding is less, the movement of the lungs and their intrathoracic structures is minimized since reflexes are retained by the patient, secretions are better controlled, and the spread of disease is reduced. It is also claimed that postoperatively the conscious patient has less respiratory depression, nausea, vomiting, and morbidity and requires less nursing care.

In spite of their virtues, none of these procedures has been employed widely. Experience in our clinics with each of them and with general anesthesia in over 600 patients suggests that these advantages are more apparent than real. In spite of intensive psychological preparation, adequate premedication, and complete analgesia, the patients operated on in our clinics with only regional anesthesia became apprehensive when the chest was opened; they later became restless, began to move, and interfered with the surgeon's task, and they frequently developed paroxysms of cough when the bronchial tree was manipulated. Moreover, many of the patients who had epidural or subarachnoid block developed a degree of hypotension which caused concern and required treatment.

In my opinion, patients undergoing intrathoracic operations do better with modern balanced anesthesia, which affords optimal operating conditions for the surgeon and better control of the patient by the anesthesiologist. Postoperative results concerning incidence of spread, morbidity, and mortality that were obtained with the general method in patients with tuberculosis operated on in our clinics have been better than those reported by the advocates of regional anesthesia.

Abdominal Operations.—The greatest decrease in the use of regional anesthesia has occurred in surgery of the abdomen. For years spinal anesthesia was considered the peerless method for intra-abdominal surgery because it provided optimal operating conditions. Muscular relaxation, unequalled by that achieved even by very deep general anesthesia, contracted intestines, quiet operating field and diminished bleeding, minimal or no effects on electrolytes, body fluids, acid-base balance, liver, kidneys, and other parenchymatous organs, and absence of depression of the respiratory center were often cited as some of the advantages of this method over general anesthesia. The same advantages have also been claimed for spinal epidural block, caudal anesthesia, and bilateral intercostal-posterior splanchnic block, which, though used with much less frequency than spinal anesthesia, have been advocated as substitutes for subarachnoid block. Field or intercostal block in combination with light general anesthesia has also been advocated for intra-abdominal operations, especially in elderly or poor-risk patients.

But while these benefits of regional anesthesia in intra-abdominal surgery have long been recognized and may be cited as arguments favoring its use, each of these techniques presents certain disadvantages which have been important factors in their replacement by general anesthesia in most surgical clinics. Since these procedures, except for field and intercostal block, interrupt all of the vasomotor segments which supply the splanchnic region, a moderate to severe hypotension usually results. In addition, there is paralysis of the lower intercostal muscles and consequent diminished tidal exchange, which admittedly may be compensated by the conscious patient. Moreover, many patients undergoing operation on the viscera of the upper abdomen, particularly the stomach, frequently experience discomfort and develop retching, vomiting, hiccoughs, and occasionally cardiovascular and respiratory disturbances. These reflex responses are due, of course, to stimulation of unanesthetized sensory pathways associated with the phrenic, vagus, and sympathetic nerves consequent to exploration of or traction on the viscera. They can be obviated by injecting these structures with a local anesthetic, but, unfortunately, many surgeons are not adept with these procedures or do not want to bother with them, so that it then becomes necessary to administer light general anesthesia and to use an endotracheal tube. The general anesthetic depresses the respiratory center and homeostatic mechanisms so that respiratory compensation is diminished and it then becomes necessary to assist ventilation. In such instances the use of regional anesthesia is still advantageous since less general anesthesia is necessary than in its absence and thus spontaneous, albeit depressed, respirations are retained. Nonetheless, these disadvantages of regional anesthesia (extensive intercostal paralysis, hypotension, frequent occurrence of discomfort, and retching), considered together with the advantages of the improved techniques of balanced general anesthesia, decrease markedly the disparity which formerly existed between the two. It is no longer a matter of comparing the profound depressant effects on the peripheral vascular bed, liver, kidneys, and heart of deep ether anesthesia administered for two or three hours for a gastrectomy with the effects of three-hour subarachnoid or peridural block.

In trying to select the best method for a patient, the anesthesiologist must compare the potential hazards inherent in the prolonged use of muscle relaxants with the potential hazards and possible disadvantages of the regional anesthetic. If the anesthesiologist is capable of administering both methods equally well, the patient and surgeon are the deciding factors. If the surgeon is gentle in exploring the upper abdomen and in placing traction on the stomach, gallbladder, or other viscera, and if the patient's condition does not contraindicate an extensive vasomotor block, regional anesthesia offers some advantages. On the other hand, if the habits and behavior of the surgeon are such that the patient is likely to experience physical and mental discomfort during most of the operation, it is far better to use general anesthesia from the beginning. Whether muscular relaxation is to be attained with a regional block or with muscle relaxants depends on the skill and experience of the anesthesiologist and the cardiovascular status of the patient. Certainly, if the patient has shock, hypovolemia, or marked arteriosclerosis, it is best to avoid regional block because, although by using vasopressors one can maintain the blood pressure, these patients fare much better with properly administered balanced anesthesia.

Although some points made in the preceding paragraphs apply to the use of regional anesthesia for surgery of the lower abdomen, there are significant differences that make this technique one of the better anesthetic procedures for operations in this region. Operations in the lower abdomen usually do not entail stimulation of the vagus and other unanesthetized sensory nerves. Moreover, it is not necessary for analgesia to extend above the seventh or sixth thoracic neurotome, so that there is significantly less incidence of severe hypotension and intercostal muscle paralysis. Regional anesthesia may be used to advantage in patients who require appendectomy, operations involving the jejunum, ileum, cecum, and colon, hysterectomy and other gynecologic procedures, cesarean section, and some urologic operations. On the other hand, in renal surgery the trend is to avoid regional techniques, such as spinal, segmental epidural, and paravertebral blocks, and to employ general anesthesia with an endotracheal tube, because the respiratory impairment consequent to the operative position and/or surgical pneumothorax requires assisted or controlled respiration.

Proper application of regional anesthesia for operations on the abdominal wall require experience and care. Small lesions may be removed with the patient under field block anesthesia and simple hernias repaired with use of intercostal block, provided there is no need for intra-abdominal manipulations. Extensive herniorrhaphy of the upper abdominal wall may be performed with the patient under spinal (subarachnoid) or epidural block anesthesia, but, if the patient's condition requires the avoidance of hypotension, it is best to use general anesthesia. On the other hand, operations on the abdominal wall below the umbilicus and in the inguinal and femoral regions constitute important clinical applications of regional anesthesia.

Operations on the Spine and Adjacent Structures.—Spinal anesthesia with use of hypobaric solution has for many years been considered the procedure of choice for operations on the spinal column because it obviates the many problems inherent in general anesthesia administered to patients in the prone position. The same claims have been made recently for spinal epidural block anesthesia. These procedures provide excellent analgesia for laminectomy in the lumbar and thoracic region and thus obviate the need for general anesthesia sufficiently deep to permit the introduction and maintenance of an endotracheal tube. Paravertebral block anesthesia is more difficult and time consuming for this purpose; it requires multiple punctures, and the results are less predictable. Since the regional methods do not affect the respiratory center, the patient is able to overcome the decrease in tidal exchange consequent to being in the prone position.

Segmental epidural block is by far the best anesthetic method with which to perform chordotomy (spinothalamic tractotomy). The segmental type of anesthesia provides analgesia for the conscious patient and optimal operating conditions for the surgeon, affording him an unparalleled opportunity for repeatedly testing sensations in the lower portion of the body during the course of the incision of the anterolateral quadrant of the spinal cord.

Perineal Operations.—Despite the general trend to use less regional anesthesia in surgery, this method has maintained its primary position for surgery of the perineum and of the lower urinary, intestinal, and genital tracts. Spinal anesthesia and, to a lesser extent, caudal and spinal epidural block are considered the procedures of choice for transurethral, perineal, and suprapubic resections of the prostate, for operations involving the urinary bladder, and for gynecologic procedures on the perineum. Since most of these procedures are done on elderly patients whose pulmonary, cardiovascular, hepatic, and renal function and electrolyte fluid and acid-base equilibrium are already burdened by age, a regional block limited to the lumbar and sacral neurotomes provides benefits in the form of lack of physiopsychological effects unmatched by those of general anesthesia. The use of the continuous technique enhances this method.

So-called saddle block anesthesia, produced either by injections of hypobaric or hyperbaric solutions into the subarachnoid space or by injections into the sacral canal (caudal block) or lower lumbar epidural space, is also considered the method of choice for anorectal operations, especially when the prone, or Buie "jackknife" positions are used. The hazards of inhalation anesthesia employed in these positions without the benefit of an endotracheal tube are obviated by the regional method. Transsacral and lumbar paravertebral block has the aforementioned disadvantages of paravertebral block and is warranted only when other regional techniques cannot be completed in patients in whom general anesthesia is contraindicated.

In recent years, the advantages of regional anesthesia in obstetrics have become fully appreciated. This method not only offers the aforementioned benefits for the mother but does not produce fetal depression. These benefits are particularly important in premature births and with cesarean sections. Moreover, regional anesthesia is the method of choice for the patient with a stomach full of undigested food.

Summary

In properly selected cases, regional anesthesia offers advantages to the patient and the physician which are difficult to duplicate with general anesthesia. It is particularly useful in emergencies and in operations of the extremities, lower abdomen, back, and superficial parts of the body. It produces less physiological disturbances during the operation and fewer postoperative complications. In obstetrics it may be preferred because of the benefits derived by the mother and infant. It offers the surgeon and obstetrician optimal operating conditions.

In order to obtain good results with regional anesthesia, it is essential to have thorough knowledge of neuroanatomy, the various block techniques, the pharmacological properties of the local anesthetic drugs, and possible complications with prophylaxis and treatment. Proper psychological and pharmacological preparation of the patient is important. Regional anesthesia is particularly useful as a diagnostic, prognostic, and therapeutic tool in the management of intractable pain and various other medical disorders.

Modern balanced general anesthesia, consisting of light inhalation and/or intravenous anesthesia and muscle relaxants, is superior to regional techniques in major operations of the head, neck, and intracranial cavity, in pulmonary surgery, and in other major operations within the chest. Balanced general anesthesia is more practical in the surgery of the upper abdominal cavity than regional anesthesia. In addition to providing better operating conditions for the surgeon, this method obviates discomfort and certain complications, such as hypotension and hypoventilation, which are particularly important problems in poor-risk patients.

ATAXIC FORM OF POLIOMYELITIS.—The early descriptions of poliomyelitis, which led to the final differentiation of this infectious disease, sometimes included an ataxic form of symptomatology. . . . Mild ataxic symptoms and muscular tremors have been described by many authors as a prelude to motor weakness. The purely ataxic form of this disease has been practically discarded by all modern authorities and is almost completely omitted from mention in current textbooks and discussions of clinical symptomatology. . . . Ataxic symptoms, and most especially sharply unilateral ataxia, are most uncommon in poliomyelitis. . . . The widespread inflammatory involvement of the central nervous system that occurs in poliomyelitis may be accompanied by many bizarre and unusual symptoms. The clinical picture of a patient is briefly detailed, simply to illustrate the occurrence of severe unilateral ataxia and signs of cerebellar involvement in a patient who proceeded to have on the opposite side of the body eventual paralysis of the tibialis anterior, typical of the late residual of poliomyelitis. The occurrence of coincidental and classical severe poliomyelitis in her 16 year old son lends almost unmistakable evidence of the nature of the pathogen.—E. B. Shaw, M.D., Ataxic Form of Poliomyelitis, *Journal of the American Medical Women's Association*, December, 1957.

CLINICAL EVALUATION OF ACENOCOUMAROL (SINTROM), AN ANTICOAGULANT OF INTERMEDIATE RANGE

Fiore R. Rullo, M.D., Carl C. Bartels, M.D.
and
James A. Evans, M.D., Boston

Acenocoumarol, an orally administered anticoagulant with intermediate duration of effect, was used in the treatment of 100 hospitalized patients. The largest group consisted of 28 patients with spontaneous acute peripheral phlebitis. The treatment was aimed to keep the prothrombin time within a therapeutic range of between 23 and 37 seconds. Many patients showed a wide range of variability, so that it was necessary to define a broader, clinically practical range between 20 and 43 seconds. The average initial dose proved to be 21 mg. of acenocoumarol, and in over one-third of the patients the prothrombin time was within the clinically practical range 18 hours later. The average maintenance dose was 6.6 mg. per day. Side-effects were few; no gastrointestinal intolerance was seen, and only five patients had minor bleeding episodes. Some patients continued to receive anticoagulant therapy on an ambulant basis after leaving the hospital, and one continued it for 64 days. This experience illustrated some significant advantages of acenocoumarol, especially the possibility of controlling the intensity of its effects and the time of their disappearance.

Since the introduction of agents that produce therapeutic hypoprothrombinemia, a search has been made for a smooth-acting anticoagulant of intermediate range. The properties which the ideal anticoagulant should possess have been enumerated by other investigators.[1] In general, the investigations in recent years have been directed toward finding an anticoagulant with a more rapid onset and shorter duration of action than bishydroxycoumarin (Dicumarol) yet one with a longer effect than the short-acting agents, such as ethyl biscoumacetate (Tromexan ethyl acetate). The synthesis of acenocoumarol (Sintrom, formerly G-23350), by Stoll and Litvan [2] in 1955 produced an agent which seems to have fulfilled these requirements. The purpose of this paper is to evaluate acenocoumarol as an anticoagulant per se and not to evaluate therapeutic results on the various diseases treated.

Acenocoumarol is a member of the coumarin series; its structural formula is shown in figure 1. It is a stable compound, supplied in 4-mg. tablets which are scored so that the patient can take the drug in increments of 1 mg. Unlike some of the other anticoagulants, acenocoumarol is odorless and tasteless [3] and is well tolerated by the gastrointestinal tract. We have found, as have Neill and others,[1a] that hypoprothrombinemia can be produced in virtually all patients in 48 hours or less and also that a therapeutic response may sometimes be expected in 24 hours.[4] According to Aeppli and Rubeli,[5] the onset of action of acenocoumarol occurs within the same period of time as that of ethyl biscoumacetate. However, acenocoumarol maintains its optimal action for 15 to 20 hours, after which recovery occurs rapidly. Recovery from the action of the drug is usually complete 48 hours after stopping administration of the drug but could take up to 72 hours if the prothrombin time were excessively prolonged (over 40 seconds).[6]

Phytonadione (vitamin K_1, Mephyton) has been shown to be effective in accelerating the restoration of acenocoumarol-induced hypoprothrombinemia to normal. The availability of phytonadione, both as an emulsion for intravenous use and as a tablet for oral administration, has provided an efficient and reliable method of reversing therapeutic hypoprothrombinemia.

Acenocoumarol is about 40 times more potent than ethyl biscoumacetate.[7] Our average maintenance dose was 6.6 mg. Two milligrams of this agent is said to be roughly equivalent to 25 mg. of bishydroxycoumarin.[1a] This potency of acenocoumarol gives it one great advantage—only small increments are required to increase or decrease dosage.

Acenocoumarol disappears from the body rapidly, but, unlike ethyl biscoumacetate, which is metabolized to an inactive form,[8] the rate of disappearance of acenocoumarol from the body is determined by its rate of excretion, apparently in an unaltered form as only small amounts of inactivated derivatives have been detected in the urine.[9] No definite relationship between dosage and weight has been observed, and it has been our experience

---

From the Vascular Section of the Department of Internal Medicine, the Lahey Clinic.

that liver function determines variation in doses between patients.[1b] The lack of gastrointestinal side-effects has been noted by several observers.[10] Liver function tests and urine examinations performed before and during the time of clinical trial have shown no evidence of toxicity.[11]

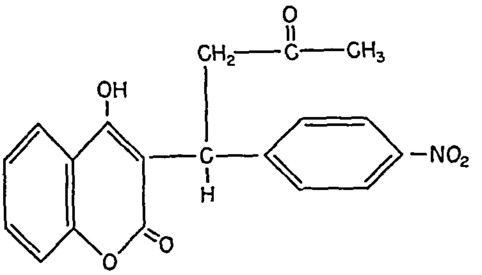

Fig. 1.—3-(α-acetonyl-*p*-nitrobenzyl)-4-hydroxycoumarin.

Materials and Methods

This report is based on our experience with 100 consecutively hospitalized patients who received acenocoumarol. Of these patients, 54 were women. The ages ranged from 13 to 84 years, with an average of 58. In general, acenocoumarol was given under the direction of only one person (C. C. B.), except that on Sunday the dose was administered by the attending physician on the peripheral vascular service. Quick's one-stage prothrombin test [12] was used to determine the prothrombin time in seconds, and this value was divided by the control time in seconds and expressed as percentage of control prothrombin time on an exponential curve (fig. 2).

The patients were divided into three groups according to the smoothness of control achieved: (1) the most desirable range theoretically, (2) a clinically practical range, and (3) an erratic range.

A value of two to three times the control (52 to 32%, respectively) was considered to be the most desirable therapeutic level. A second group was made of those with prothrombin times within a clinically practical range, which included times falling within 60 and 28% (20 and 43 seconds, respectively, with use of an average control thromboplastin time of 12 seconds). It has been our experience in 16 years of anticoagulation therapy that extension or recurrence of venous thrombosis or embolism is exceedingly rare at prothrombin levels of 60%. Hemorrhage is rare above 28%.

The tablets of acenocoumarol, including the loading doses, were administered once daily—usually between 3 and 6 p. m. Blood for prothrombin time determination was usually drawn between 7:30 and 9:30 a. m. Thus, the prothrombin time was known before the daily dose of acenocoumarol was ordered.

This report deals only with patients who were hospitalized and received acenocoumarol on a short-term basis.

Reasons for Anticoagulation Therapy

One-fourth of the patients received acenocoumarol as a postoperative prophylactic measure; 9 of these gave a previous history of acute phlebitis and one of pulmonary embolism, 12 patients were given anticoagulation therapy after ligation and stripping for varicose veins, and 3 were given the drug for debilitation. In most of these cases, acenocoumarol was begun on the second or third postoperative day.

The largest group, including 28 patients, had spontaneous acute peripheral phlebitis. These patients had isolated phlebitis and were not grouped with those with chronic recurrent phlebitis, of whom there were seven. A significant proportion of the total group (10%) were treated because of symptoms and signs of cerebrovascular thrombosis or insufficiency, usually occurring as basilar artery or internal carotid artery syndromes. Most of the patients with chronic relapsing thrombophlebitis and those with cerebrovascular insufficiency continued to receive anticoagulation therapy with acenocoumarol on a long-term ambulatory basis. Other conditions for which this treatment was given included acute postoperative peripheral phlebitis (13), acute pulmonary embolus (10), acute myocardial infarction (3), postoperative sympathectomy after arterial thrombosis (2), lymphedema precox (1), and persistent angina pectoris (1).

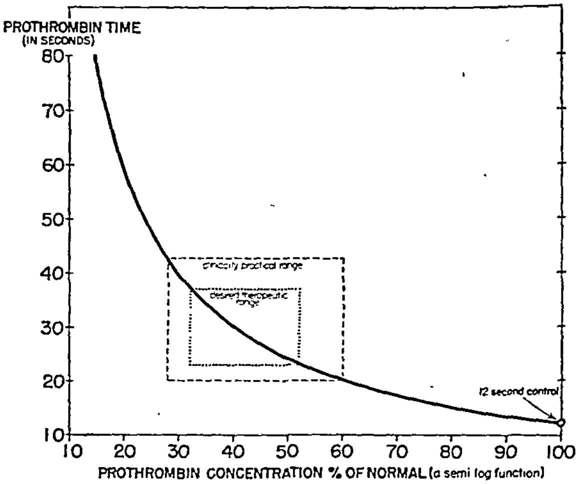

Fig. 2.—Curve of prothrombin time in seconds plotted as percentage of control prothrombin time of 12 seconds.

Dosage and Duration of Treatment

The initial dose of acenocoumarol was 24 mg. in 52 patients, and the smallest loading dose was 4 mg. The average initial dose was 21 mg. for the entire group. None of our patients received more than 24 mg. as an initial dose. The dose on the second day ranged from zero to 20 mg. and averaged 11.4 mg. These dosages were similar to those of other investigators,[13] although initial doses up to 40 mg. have been administered.[14] The dose on the second day was usually 4 to 8 mg. less than the initial dose.

The prothrombin time 16 to 18 hours after acenocoumarol therapy was begun (that is, the second treatment day) averaged 66.2%. Thirty-seven patients had a prothrombin time of less than 60% on the second treatment day, and 63 patients had a prothrombin time of less than 75% on the second treatment day. This means that in over one-third of the patients the prothrombin time was in the practical therapeutic range 18 hours after therapy was started. The average maintenance dose was 6.6 mg.; this is slightly higher than the 5.9-mg. dose noted by Neill and others.[13] The range of the daily dose was from an average low of 3.6 mg. to an average high of 11.3 mg.

The minimum duration of therapy with anticoagulants was 5 days; however, one patient was treated for 64 days. The average length of anticoagulation therapy while the patient was in the hospital was 10.6 days. This figure would seem to indicate a relatively short duration of anticoagulation therapy. However, it should be noted that a large group (25%) received such therapy only as a postoperative prophylactic measure and also that several other patients went on to receive this treatment on an ambulatory program as soon as the maintenance dose was established in the hospital.

Efficacy of Control

A total of 852 prothrombin time determinations was performed, excluding the determination after the initial dose of acenocoumarol. Five hundred twenty (61%) of the prothrombin times fell within the 52 to 32% therapeutic level. This figure would be appreciably increased if the prothrombin times of less than 32% were included. In no case did the prothrombin time fall to less than 19%. The greatest number of prothrombin levels below the 32% level were in the 22 to 26% group, which is still not in a danger zone—especially for the hospitalized patient, with the ready access to intravenously or orally given phytonadione.

Six hundred seventy (79%) of the prothrombin concentrations fell within the clinically practical therapeutic range (prothrombin times between 60 and 28%). In 48 patients they were noted to be below 28%, at least at one determination. Again, none was lower than 19%. In other words, 83.6% of the prothrombin concentrations were consistently below the 60% level by the third day and after. In regard to the individual patient's response to acenocoumarol, 31 patients had prothrombin times in the therapeutic range over 75% of the time and 70 had clinically practical control over 75% of the time.

Eight patients were out of the 28 to 60% range at least half the time and came under the category of erratic range.

Figure 3 shows typical therapeutic responses; figure 4 (*left*) shows a patient within the clinically practical therapeutic range, and figure 4 (*right*) illustrates the erratic range that can occur with acenocoumarol.

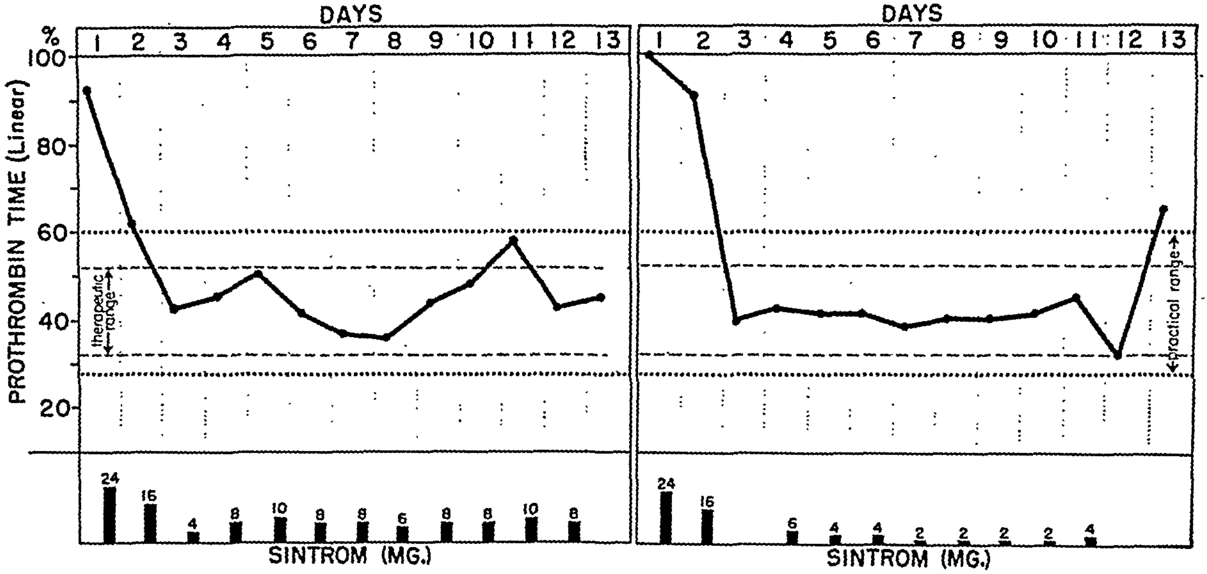

Fig. 3.—Typical therapeutic responses to acenocoumarol (Sintrom). *Left*, curve of prothrombin time in 64-year-old man with acute phlebitis and acute pulmonary embolus. Except on 11th day, prothrombin time stayed consistently within therapeutic range. Note small increments of dosages required. *Right*, curve in patient with acute thrombophlebitis of thigh after mid-thigh amputation, showing smooth control similar to that obtained in many cases with only small increments in dosages.

Comment

We found acenocoumarol to be a feasible and interesting anticoagulant which caused only a small number of complications. Only five patients manifested minor bleeding episodes. One patient had a petechial rash of one extremity which developed on the sixth day of treatment. A platelet count on the following day showed a level of 154,000 per cubic millimeter, and this was unchanged two days later. Marrow aspiration five days after the rash showed an essentially normal bone marrow with a slight increase of eosinophils. Bleeding from a T tube and from around a urinary catheter was seen in two patients. One patient reported about 10 cc. of blood with a bowel movement; however, anticoagulation therapy was continued without further difficulty. The fifth patient had rheumatic heart disease with auricular fibrillation and recurrent pulmonary emboli. Acute phlebitis of the femoral vein also developed in this patient early in his hospital stay, and it was then that anticoagulation therapy was begun. It was continued despite persisting bloody sputum and, at times, gross clots in the sputum. The patient received ambulatory anticoagulation therapy for several months. This patient probably does not warrant inclusion in the group with unfavorable reactions, but his case is included for the sake of completeness and interest.

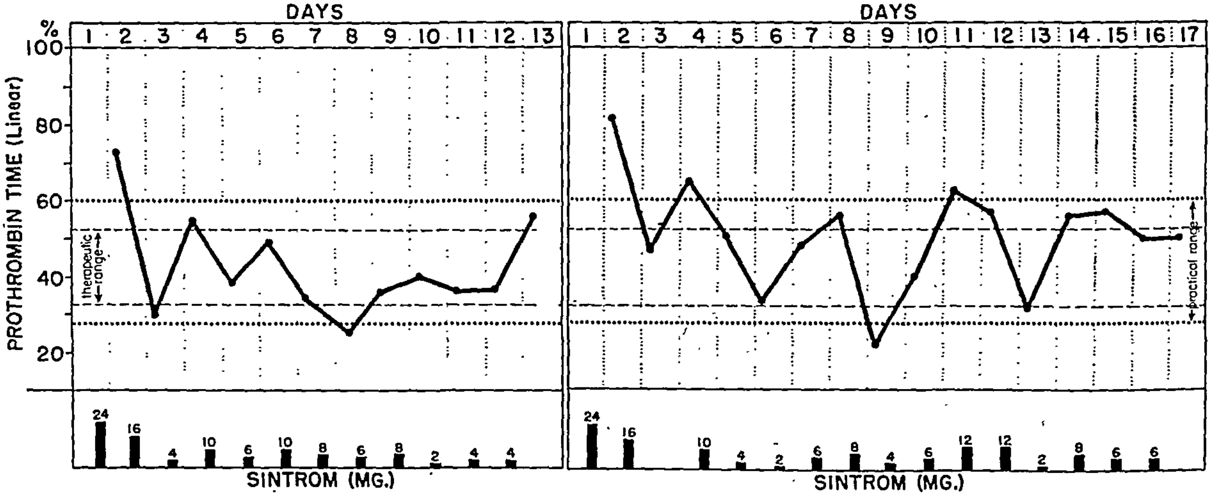

Fig. 4.—*Left,* curve of prothrombin time in 45-year-old man with acute phlebitis. Prothrombin time throughout administration of acenocoumarol (Sintrom) remained consistently within clinically practical range. *Right,* curve in 68-year-old woman with chronic thrombophlebitis and episode of acute phlebitis before admission. Note erratic response to acenocoumarol after omission of daily dose; smaller increments in doses might have produced smoother effect.

No gastrointestinal intolerance was observed, nor did the patients find the tablets to be distasteful. The one-dose-a-day treatment was appreciated by the patient and by the medical and nursing staff. Performance of emergency prothrombin time determinations was rare.

Especially reassuring was the knowledge that the group with low prothrombin levels made a fairly rapid return to a safe range. It was noted with this group that if the patient were allowed to go without acenocoumarol on a day when the prothrombin time was below a safe level, the smooth control levels were attained only with difficulty; several such patients eventually showed erratic curves (fig. 4 *right* and 5). In these cases, it would seem to be advisable to give one-half or one-third of the usual maintenance dose to prevent the escape from smooth control. However, even though a patient had a minor bleeding episode or the laboratory reported a low prothrombin time, the omission of the daily dose, without any other treatment, would allow the prothrombin time to return to a safe level at a fairly rapid rate. This fact makes the drug safer for use in treatment of ambulatory patients.

Admittedly, the clinically practical level is an arbitrary classification. Yet, we feel its use is justified, as this is a clinical report involving a number of variables which must be included in the everyday practice of medicine. Wright and others [15] have concluded that all prolongations of the prothrombin time during bishydroxycoumarin therapy (including the *minimal ones*) were associated with a substantial reduction in thrombotic episodes.

We found, as had other observers,[16] that the initial loading dose should be followed by a substantial, though reduced, dose on the second day. Patients who received less than the usual dose on the second treatment day were more likely to have an erratic response.

Forty-two patients received heparin sodium (Depo-solution) as an intramuscular injection in one or more doses on the first day of treatment with acenocoumarol or on the day before or after the initial dose of acenocoumarol was administered.

Summary

In a review of 100 hospitalized patients who received acenocoumarol (Sintrom) as an anticoagulant, this agent was found to be dependable and its effects were predictable. For the most part, this study confirms the findings of other workers. The only toxic reactions observed were a few minor hemorrhagic manifestations—an accepted risk for anticoagulation therapy with any agent. Two of the five patients who experienced slight hemorrhage continued to receive anticoagulation therapy without further incident.

The prompt effect of acenocoumarol, within 48 hours, and the following loss of effect within the same length of time lead to rapid control of thromboembolic disease and to quick control of hemorrhage. The small increments required in change of dosage add to the accuracy and smoothness of control. Smoothness of control is also obtained because acenocoumarol maintains sufficient prolongation of the prothrombin time to allow a 24-hour period to elapse between doses. The use of acenocoumarol as an anticoagulant of intermediate range provides a useful and reliable tool for the proponents of anticoagulation therapy.

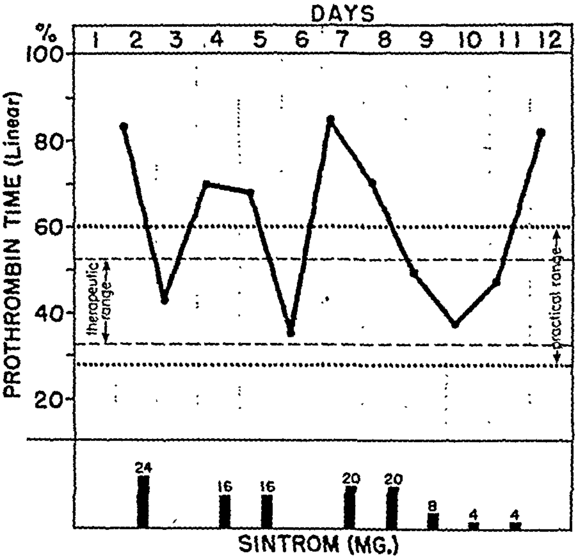

Fig. 5.—Curve of prothrombin time in 61-year-old woman who had phlebitis 13 days after subtotal thyroidectomy was done. Note omission of daily dose of acenocoumarol (Sintrom) and difficulty in controlling prothrombin time.

80 W. Main St., Attleboro, Mass. (Dr. Rullo).

Miss Sherbie Mayhew provided technical assistance in preparing the data for this study.

The acenocoumarol used in this study was supplied as Sintrom by Geigy Pharmaceuticals, Ardsley, N. Y.

ORAL DIAGNOSIS OF SYSTEMIC DISEASE

Eugene S. Hopp, M.D., San Francisco

Enamel hypoplasia may be produced during the formation period of enamel matrix by nutritional deficiency (particularly vitamins A and D), endocrine dysfunction and generalized infection as in the exanthemas, and prenatal syphilis. Gingival hyperplasia may occur in puberty and in pregnancy and sometimes in patients receiving diphemylhydantoin sodium. Oral pigmentation can be caused by the administration of a bismuth, silver, or lead preparation. Quinacrine hydrochloride produces a yellow-brown pigmentation in the cuspid regions and a yellowish oral mucosa. Anemia may be readily diagnosed by examination of the tongue. There are a number of mouth lesions which are closely associated with tension and nervous strain. These include periodontal disease, aphthous stomatitis, acute necrotizing gingivitis, erythema multiforme, lichen planus, and probably pemphigus. It has been strongly suggested that the lesions of lichen planus, some 50% occurring only in the mouth, are the product of psychic stimulation. Chronic emotional tension, producing a change in the chemistry of saliva, can be the cause of periodontal disease.

There are two opposite poles on the question of the ability to diagnose systemic disease by examination of the mouth. At one extreme is Kreshover.[1] He writes that, unfortunately, many dental and medical practitioners are overly impressed by the seemingly remarkable ability of some clinicians, essayists, and authors to make diagnoses merely by examining an isolated lesion in or about the mouth. Too often, says Kreshover, the expert fails to mention the essential part played by consultants and laboratory technicians in providing a correct diagnosis. At the opposite pole is a discussion aptly titled "The Tell-Tale Mouth" by Fabricant[2] who says that the mouth provides otolaryngologists with a unique opportunity to observe the earliest findings of systemic disease.

The two viewpoints are not completely irreconcilable. It is indeed true that certain physiological changes such as pregnancy, growth period, lactation, and aging may of themselves produce nutritional deficiencies by increased demands on the organism. These deficiencies are often manifest in mouth changes which cannot be differentiated clinically. It is also true that the laboratory and the consultant may both be required to confirm a clinical impression. But how much worse it would be not to be able to gain a clinical impression from an examination of the mouth and thereby delay confirmation of a diagnosis until irreversible damage had been done.

Much has been written on the appearance of the mouth in a multiplicity of systemic conditions. I shall briefly outline and review some of these and then discuss a phase of oral diagnosis which has been neglected—the psychosomatic.

Appearance of the Mouth in Systemic Disease

Changes in Teeth.—Enamel hypoplasia may be produced during the formation period of enamel matrix by nutritional deficiency (particularly vitamins A and D), endocrine dysfunction and generalized infection as in the exanthemas, and prenatal syphilis. Enamel hypocalcification is most frequently produced by excessive fluorine in the drinking water. One part per million of fluoride in the water supply has been shown[3] to reduce children's dental decay by 50 to 60%. Fluorosis has been reported[4] in communities with a natural water fluoride level of 8 ppm. To cause the mottled enamel of fluorosis the water must contain more than 1 ppm of fluorine and be consumed during the tooth development period.

Changes in Gums.—Gingival hyperplasia may occur in puberty and in pregnancy. In puberty, there is increased size of the papillae and thickening of the gingival margin due to hyperemia, edema, and increased vascularity. Establishment of hormonal balance is curative. Pregnancy gingivitis is quite similar, and local irritation is a common precipitating factor. A small percentage of patients with pregnancy gingivitis develop localized tumors of the gums.

Gum hyperplasia develops sometimes in patients receiving diphenylhydantoin (Dilantin) sodium. Gingivoplasty may be necessary where continuation of the therapy is required. Leukemic hyperplasia is characterized by a marked increase in tissue bulk due to an infiltration of cells. It is most common in monocytic and granulocytic (myelogenous) leukemia. In general, surgical procedures are contraindicated.

Oral Mucosa.—The oral mucosa often reveals systemic pathology. Oral pigmentation can be caused by the administration of a bismuth, silver, or lead preparation. A dark blue pigmentation can usually be seen in the buccal mucosa. Quinacrine

(Atabrine) hydrochloride produces a yellow-brown pigmentation in the cuspid regions and a yellowish oral mucosa. Such pigmentation may also occur in jaundice, carotinemia, hemochromatosis, and adrenal cortical hypofunction (Addison's disease).

Changes in the Tongue.—The tongue is more frequently diagnostic in avitaminosis than are other areas of the mouth. The nutritional disorder most often visualized in the mouth is vitamin B complex deficiency. This B complex group includes thiamine, nicotinic acid, riboflavin, cyanocobalamin, folic acid, pyridoxine, choline, biotin, and pantothenic acid. It is rare that but one of the group is involved. Clinically, the tongue is edematous, rather purplish, and with enlarged fungiform papillae. Angular cheilosis and circumoral pallor generally complete the clinical appearance.

Anemia may be readily diagnosed by examination of the tongue. In pernicious anemia, there is, in the early stage, a red, sore tongue and then later, pallor and atrophy of the dorsal surface of the tongue with redness of its margin. In polycythemia vera, the tongue is engorged and cyanotic. In agranulocytosis there is often a gangrenous area in the tonsil or pharynx. The tongue during scarlet fever, the Koplik spots of measles, and the pharyngeal vesicles of chicken pox are all too well known to require additional description.

Miscellaneous Effects.—Drug idiosyncrasy may affect various areas of the mouth. Black hairy tongue is not uncommon after antibiotic therapy. It occasionally occurs after x-ray therapy or in patients with a gastric ulcer. Superficial necrosis, swelling, and ulceration of the gingiva have been reported in 48 hours after the administration of pyridium for urinary infection. Tuberculosis, syphilis, histoplasmosis, and actinomycosis may all produce mouth lesions which tax clinical acumen and yield their diagnosis only to laboratory study.

Psychosomatic Lesions

Though this list of mouth lesions associated with systemic disease is far from complete, I should like to turn to the psychosomatic group. F. P. McCarthy and P. L. McCarthy[5] reported on 4,728 mouth cases and described 11% of the oral lesions as due to psychic causes. In 574 patients, the lesion or symptom was cancerophobia (more often related to tongue) in 216 cases, papillitis in 211, oral lichen planus in 97, habit biting in 27, ptyalism in 15, cheilitis exfoliativa in 6 (of 40 cases), and syphilophobia in 2.

Chavoor[6] points out that chronic emotional tension, producing a change in the chemistry of saliva, can be the cause of periodontal disease. Tension by affecting the autonomic nervous system can alter circulation and reduce tissue resistance of the oral musoca. One can readily see how this might promote bacterial and viral invasion.

Moulton[7] has made an excellent study of the relationship between anxiety and oral lesions. She points out that the mouth is the earliest area for pleasurable satisfaction and many adults continue to utilize it for the same purpose in their eating, drinking, smoking, or sexual enjoyment. Phobias about immobilizing the mouth often develop because of its vital part in eating and breathing and primitive defense. Dr. Moulton emphasizes the special sexual symbolism of the mouth in women and states that oral bleeding is frequently used in dreams to refer to rape, menstruation, and abortion.

There are a number of mouth lesions which are closely associated with tension and nervous strain. Acute necrotizing ulcerative (Vincent's) stomatitis was once presumed to be an infectious disease. But transmission of the clinical state has never been consummated by the use of the organisms. Simultaneous spread of ulcerative stomatitis among groups of soldiers is now believed to be due to a similarity of stress conditions.

The oral lesions of the erythema multiforme group are on the increase. This group includes Stevens-Johnson's, Behcet's, and Reiter's syndromes. They are probably all variants of erythema multiforme exudativum, described by Hebra in 1860. Typically, stress plays a part in etiology. A typical patient was a female with a diabetic child of whom she was the sole support, her husband having deserted her. Her mouth ulcerations improved rapidly on steroid therapy, but she developed a recurrence of the lesions when she had to stop working temporarily to care for her child and another recurrence when a situation arose at work which she could not handle.

It has been strongly suggested[5] that the lesions of lichen planus, some 50% occurring only in the mouth, are the product of psychic stimulation. Aphthous stomatitis is perhaps the commonest mouth lesion seen and the most puzzling with regard to etiology. A careful study of the history frequently reveals that these lesions begin after an acute emotional upset. They occur more frequently in women during pregnancy and menstruation, and some varieties are associated with functional gastric symptoms. The mouth lesion itself suggests vasospasm or minute infarction of the area of mucosa involved.

Pemphigus almost always produces mouth lesions. Several acute and chronic varieties have been described. The etiology of pemphigus is unknown. One variety is probably a variant of erythema multiforme. The possible association between pemphigus and stress has not been carefully investigated. Steroid therapy has been the only medication of any real benefit in pemphigus.

Recommended Treatment.—What can be done for all these psychosomatic problems? In general, little may be expected from psychiatric care. One must be careful not to overdiagnose by calling the patient's attention to minor anatomic variations which then become a fixation. One must be careful not to overtreat, as these patients frequently request oral surgery or dental extraction because of their mental distress. Perhaps the most important therapy is a careful taking of the history, listening to the patient, and giving him an opportunity to discuss freely his local difficulty and sometimes any general problem. Careful examination and then adequate explanation of the nature of the process is a necessary part of successful therapy. This can be supplemented to advantage in some instances by sedation, tranquilization, or mild topical therapy. By these means, a problem patient may frequently be converted to a grateful one.

AMERICAN UROLOGY'S OBLIGATION TO THE WORLD

Roger W. Barnes, M.D., Los Angeles

It is agreed that the scientific knowledge of urology accumulated in this country should be shared with other countries by giving urologic training to foreign medical graduates. This can be done either by training foreign students in this country or by enabling American urologists to visit other countries to give courses there. Each plan has its advantages, and much depends on the teacher.

The United States has become the leader of the free world. We can no longer be isolated and self-contained. Our prosperity depends to a large extent on the prosperity of other countries. We must share our scientific knowledge and industrial know-how with the people of other nations if we ourselves are to progress and prosper. This concept includes the sharing of our knowledge in every field of endeavor.[1] We, as physicians and as urologists, are obligated, under this concept, to do what we can to improve the standard of the practice of medicine in other countries where scientific advancement has not been as rapid as it has been in the United States.

American medical men are doing their share to help other countries. During 1956-1957, 6,741 physicians from 88 countries were in training in United States hospitals; residents numbered 4,753 and interns 1,988. During the same period 81 physicians from American medical schools were abroad teaching in foreign institutions.[2] During 1957-1958 there were reported to be 142 foreign physicians training in urology in the United States.[3]

In order to obtain the opinion of urologists who might have the opportunity of giving urologic training to foreign medical graduates, a short questionnaire was sent to each of the chiefs of urology services which are approved for giving residencies.[4] One hundred ninety-eight questionnaires were sent out and 153 were answered and returned.

There were 142 in favor of and 7 against giving urologic training to foreign medical graduates; 3 did not answer the question. Ninety-nine chiefs of services who were giving this training reported that a total of approximately 450 foreign doctors had been given nine months or more of urologic training in their institutions. These data show, I believe, that the majority of American urologists are aware of our national obligation to the countries who are less fortunate than we. Most of those who are in a position to do so are accepting this obligation. In addition to this training in the United States, American

Chairman's address, read before the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

urologists have made 90 trips to foreign countries to help give urologic training to foreign graduates in their native land.

The language difference is sometimes a barrier to giving training to foreign doctors. English is, however, the most universal language and medical courses are taught in English in most of the countries of the Middle East, from the Mediterranean to the borders of China, and also in the Philippines. There is very little language difficulty with students coming from these countries or with teachers going to them. However, many desirable trainees from the Latin American countries and from Japan and Free China cannot be accepted here because they do not know English; and urologists going to them are limited in their activities unless they know their language.

For practical application it is more feasible to give urologic training to foreign graduates here in the United States than for American urologists to go abroad to train them. This was the opinion of 110 of the chiefs of services who answered this question. Thirty-five thought it was more practical to give the training to the foreign graduates in their own country. Seven had no opinion or thought both methods were practical.

It is less disturbing to us to give urologic training to a foreign medical graduate here than for one of us to go to another country for a year or two. The foreign graduate who has had adequate basic training and has sufficient knowledge of English to talk to patients and to understand lectures and conferences can usually fit into the training program nicely. Some of them, however, have had inadequate medical education in their own country and require more basic training here during their residency than do the other residents on the service. When they are deficient in their medical knowledge and/or in their knowledge of English, they cannot carry their share of the load of work and are unable to accept responsibility. These situations are more or less disrupting to the training program. Some have difficulty obtaining registration in the state where they are to take their residency.[5]

A facility to screen foreign medical graduates for internships and residencies in the United States has recently started to function. The Educational Council for Foreign Medical Graduates[6] is sponsored by the American Hospital Association, the Association of American Medical Colleges, the American Medical Association, and the Federation of State Medical Boards of the United States. Dean F. Smiley, formerly secretary of the Association of American Medical Colleges, is executive director. This facility gives examinations to foreign medical graduates and checks their credentials. Foreign applicants obtain certification from the facility on the following qualifications: 1. Their education has met minimal standards (18 years of formal education, including at least 4 years in a bona fide medical school). 2. Their command of English has been tested and found adequate for advanced training in an American hospital. 3. Their general knowledge of medicine as evidenced by passing the American Medical Qualification Examination is adequate for assuming an internship in an American hospital. Chiefs of services and hospitals can eliminate most of the undesirable foreign applicants by requiring certification by this facility.

Foreign medical graduates who come to America to learn to be urologists receive a more thorough training here in most instances than they would from an American urologist going to the foreign country. The excellent equipment, the number of faculty personnel, and the opportunities for research here all facilitate the giving of a thorough training. The results of the questionnaire on this point were that 137 thought more thorough training could be given in the United States, 4 had the opposite opinion, and 7 had none.

Urology in Other Countries

Are foreign medical graduates able to establish urology on a sound basis in their own land after they have finished their training here and have returned home? Of those who answered the questionnaire, 78 thought they could, 49 believed that it was preferable for American urologists to go abroad, and 15 had no opinion or thought the two were of equal benefit.

When the young urologist returns to his native city after having finished his training here, he is in most instances still considered a home town boy. Most of the senior surgeons knew him when he was born and are not likely to consider his opinions of very great value. It is often difficult for him to get enough cases from the general surgeons or others who have always had them. His requests for equipment are often ignored or considered lightly, and his efforts to organize a department or to improve one which is already established may be of no avail. Conversely, when a qualified American urologist goes to a foreign institution to train urologists there, he is recognized as an authority by the administration and by other staff members. His plans will usually be accepted and his requests granted. His influence carries weight. He can establish the specialty on a sound basis more rapidly than a young national who has come back home. If the men he is training there are able and intelligent, the training program will continue to progress after he leaves.

Were it possible for a large number of qualified American urologists to go to a foreign institution to give training, a large number of foreign medical graduates could obviously be trained. Approximately 90 trips to foreign countries were made by those who answered the questionnaire or by someone else in the department for the purpose of training urologists there. Most of these were short lecture tours; a few were for a longer time. The short visits are beneficial to the training program in the foreign country, but a longer stay of a year or more can accomplish a great deal more. Even then, however, it is not possible to have more than six or eight trainees at a time, even in the large centers where there are abundant clinical facilities. Therefore, it would take a long period of time and many American urologists to train in their own country the 450 or more foreign medical graduates who have been trained in this country.

It was the opinion of 61 of those who answered the questionnaire that the largest number of foreign doctors could be given training in this country, 70 believed that more could be trained by American urologists going to the foreign country, and 22 had no opinion. It is probable that many were of the opinion that the majority of those trained in this country either remained here or came back later. The result of the questionnaire was, however, surprising in this regard. Of the 450 foreign doctors who were given urologic training here, 296, or 65%, were reported as having returned to their country and remained there or were still in training here and were planning to go back. The chief objective of giving urologic training to foreign doctors is to advance the specialty of urology in their own country. There are many attractions in this country, however, which make it desirable for them to remain here. Some of the best men are offered positions in our own institutions. Many are attracted so much by our way of life that they do not want to live again in their own country.[7] One of the urologists who answered the questionnaire wrote "we can do a lot of good toward better relations with our neighbor countries. The number who want to stay here is really a compliment to our country." This attitude is, in my opinion, typical of the unselfish American who is proud of his country and is glad that those from foreign lands like it so well that they want to remain here. Even though approximately 35% of the graduates of foreign medical colleges who receive urologic training here remain in this country after completion of their training, enough go back to make it well worth while to train them. A law (public law 555) enacted in 1956 may help to ensure that these physicians return to and remain in their native country.[8]

I spent last year in India at the Christian Medical College in Vellore as a Fulbright exchange professor.[9] I was able to complete the urologic training of a very competent national surgeon and to start a training program which will, I am sure, continue. It is now the only place in all of southern Asia where urologic training is given. However, the absence of a professor or of a chief of service from his department here at home for a year or two may present a number of problems. There may be no one capable of carrying on his work either in the department of the medical college or hospital or in his private practice. He may be so involved financially he could not meet his obligations with the reduced income which usually accompanies service abroad. His family may be unwilling or unable to go to a foreign country.

A sojourn of a year or more teaching in a foreign country is rewarding in many ways. There is satisfaction of accomplishment, a need is filled, a training program is established, or a department which has already been started is upgraded. The American teacher who goes abroad to train nationals is one of the best emissaries of good will from this country. A change of environment is helpful to the individual who makes the sojourn. His absence from his department may even be of benefit to it by stimulating others to take more responsibility. Sometimes we think we are indispensable; our absence for a year or more may change this concept. While we are away, many responsibilities are assumed by others who may be more capable than we of handling them. When a man has been in one position for many years, it broadens his viewpoint, disrupts many of his fixed habits, and develops patience and tolerance to be in a different environment which is not as smooth running and efficient as his department at home.

There is adventure in an assignment to a teaching position in a foreign institution. The country and the people and the customs are new and different to him. A man can enjoy his travels and at the same time have the satisfaction of accomplishing something worthwhile. When he has finished his assignment, the gratitude of those whom he has gone to help will in itself far outweigh any inconveniences and hardships he has encountered.

The man who accepts a teaching assignment in a foreign institution must be adaptable; he must be resourceful; and he must have patience and persistence. It is necessary for him at first to tolerate customs and habits which, to his mind, are inefficient and cumbersome. Then by resourcefulness and by patience and persistence he endeavors to make the changes which are most necessary to upgrade the department. A man who cannot be content with anything less than perfection would be frustrated. Perfection is a goal to work toward but is often not obtainable in most foreign institutions. The man who cannot work unless supplies, equipment, and personnel are nearly perfect would be unable to tolerate any more than a lecture tour in these environs.

Summary

American medicine has accepted its portion of the obligation to share our scientific knowledge with other countries. Leading urologists here agreed 142 to 7 that we should give urologic training to foreign

medical graduates. Approximately 450 had been or were being trained in the United States; approximately 90 trips have been made to foreign countries by American urologists for the purpose of giving urologic training abroad. The advantages of giving training in the United States are that it is more practical, more thorough training can be given under the present circumstances, a larger number can be trained here, and foreign graduates who desire graduate training here can now be screened by the Educational Council for Foreign Medical Graduates. The advantages of giving training to foreign graduates in their own country are that it establishes urology on a firmer basis in their country and it is stimulating, interesting, and satisfying to the teacher. Medical men who are not adaptable, who are extreme perfectionists, and who do not have patience and persistence would not enjoy foreign service for more than a few weeks.

MINIATURE R-WAVE CARDIAC MONITOR

EARLY DETECTION OF CARDIAC ARREST DURING SURGICAL OR ANESTHETIZATION PROCEDURES

William F. Veling, M.D., Detroit

An estimated 5,000 deaths occur yearly because of cardiac arrest during surgical or anesthetization procedures, and it is obvious that a significant void exists in our armamentarium which urgently requires some attention.[1] Resuscitation procedures on the heart are both possible and consistently successful if instituted literally within seconds of the time of actual arrest. It is generally agreed that success depends in large measure on immediate diagnosis and decisive action.[2]

When one is confronted during operation with a sudden fall in blood pressure and peripheral circulatory collapse to the extent that no heart sound or pulses are obtainable, one very important question must be answered without delay: is this shock, with the patient's heart beating imperceptibly, or has cardiac arrest or ventricular fibrillation occurred? The use of blood, fluids, or vasopressor agents in such a situation will eventually assure one of the diagnosis, but if the condition is the result of cardiac arrest the opportunity for successful resuscitation may be lost. The specific purpose of a cardiac monitor is to give some warning of impending disaster and to aid in making an immediate diagnosis once arrest or fibrillation has occurred. Such a device is intended to assist the anesthesiologist, not to supplant him or convert his specialty to automation. Careful observation of the peripheral pulses, the blood pressure, skin, mucous membranes, and auscultatory findings are time-

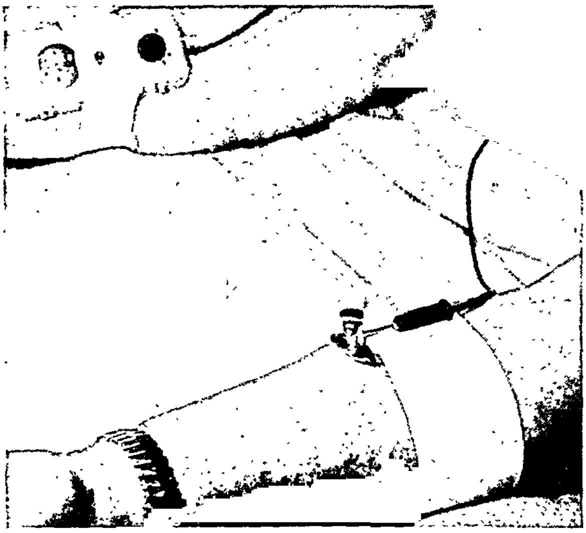
The specific purpose of a cardiac monitor is to give some warning of impending disaster and to aid in making an immediate diagnosis once arrest or fibrillation has occurred. Such a device is intended to assist the anesthesiologist, not to supplant him or convert his specialty to automation. A miniature cardiac monitor that can be affixed to the patient has been developed to fulfill the need for a small, rugged, reliable, and relatively inexpensive instrument suitable for mass coverage. Plug and jack-type connections have been avoided to minimize faulty electric contact and resulting "false alarms." The audible "beep" enlists the attention of the entire operating room team but frees their eyes and hands for other duties.

From the Department of Surgery, Grace Hospital.

honored and reliable indexes of cardiac function. The physician's perceptive abilities and his clinical judgment cannot be replaced by electromechanical robots, but in certain situations, such as cardiac arrest, his decisions can be made more quickly.

Nature and Function of Cardiac Monitors

Currently available cardiac monitors depend on a variety of secondary manifestations of cardiac activity for their activating signal. Some monitor the peripheral pulses or the blood pressure, others rely on amplified heart sounds, and some monitor the electric potentials of the heart. Since a knowledge of the electric activity of the myocardium is our most accurate index of its action, short of direct observation, and since monitoring of the electric potentials is both possible and practical, other forms of monitors which depend on peripheral circulation or on heart sounds are at best only poor substitutes for the anesthesiologist and the stethoscope and sphygmomanometer which he has used for years.



Miniature cardiac monitor, showing right and left forearm electrode connections.

Instruments now available which technically are excellent monitors leave much to be desired with regard to practicability. Many require the undivided visual attention of the anesthesiologist or of a cardiologist, and complex control systems require adjustment by someone familiar with the operation of complicated electronic apparatus. They are generally large in size, have high-voltage circuits for cathode-ray tube displays, delicate meters, and long connecting wires for one to trip over, and are susceptible to damage from incorrect or rough usage. High initial cost and maintenance add to the big question of practicability, especially when one envisions the use of any of the currently available monitors on a large scale. Since the occurrence of cardiac arrest or ventricular fibrillation is quite unpredictable, monitoring should be done in all patients undergoing surgical or anesthetization procedures from the time they leave their beds for the operating room until they have reacted in the postoperative recovery room. The desirability of monitoring the critically ill patient and the patient with coronary disease could also be considered. A 400-bed hospital should probably have 40 monitors available (10% of the general hospital beds). For most hospitals the storage of a number of the larger sized units would be impossible.

The Miniature Cardiac Monitor

A miniature cardiac monitor has been developed to fulfill the need for a small, rugged, reliable, and relatively inexpensive instrument suitable for mass coverage. It is a completely self-contained unit which weighs less than 6 oz., including battery power supply and a high-gain transistor amplifier. The metal case is designed for mounting the unit directly on the body and serves as one electrode. A small external lead wire is permanently fixed to the amplifier and to a second electrode. Plug and jack-type connections have been avoided to minimize faulty electric contact and resulting "false alarms."

Although the right and left forearm electrode connections are commonly used, any standard two-lead electrocardiographic configuration may be used, depending on the surgical requirements.

Mounting the entire instrument on the patient (see figure) allows freedom of movement, decreases the number of lead wires to one, and protects the monitor from accidental damage which is prone to occur with distantly placed units having several long connection leads.

A single manual control for sensitivity selection is all that is needed to "tune" the instrument. Adjustment of the sensitivity may produce audible combinations of the electrocardiographic complex in whole or in part, but the usual desired signal is a clear, loud "beep" tone occurring with each R wave. A pressure-activated microswitch turns the monitor on when it is fixed to the patient and conserves batteries by automatically turning it off when it is removed.

Operation and control has been so simplified that, in many cases, by the mere application of the instrument a satisfactory signal will result without further adjustment. The audible "beep" enlists the attention of the entire operating room team but frees their eyes and hands for other duties. The constant attention required by visual indicators, such as meters, lights, or the cathode-ray tube displays, is thus eliminated.

Where it is desirable to use the monitor away from the body, as in surgery on infants, provision is made for an alternate electrode lead. The amplified signal is made available through another connection for activating an external light or meter indicator, such as would be required in the recovery room or when the monitor is used in the hospital wards.

Protection of the amplifier circuit, including the transistors, from moisture and corrosion is obtained by embedding the unit in plastic resin. This also makes the monitor extremely resistant to the hazards of accidental dropping or rough usage. The design lends itself to the advantages of mass production, and it is anticipated that such an instrument will soon be commercially available at a moderate price.

Conclusions

The purpose of a cardiac monitor is to assist the anesthesiologist by giving warning of impending disaster and by aiding in the establishment of an immediate diagnosis. Small, reliable, rugged, and easy to operate and maintain, a miniature cardiac monitor, with its reassuring "beep," could become as commonplace as the stethoscope in the operating room.

TWO YEARS' EXPERIENCE WITH CHEMOPALLIDECTOMY

Harold D. Paxton, M.D.
and
Robert S. Dow, M.D., Portland, Ore.

Fifty-three patients underwent chemopallidectomy as treatment for dystonias believed to originate in the basal ganglions. In 43 the symptoms were those of Parkinsonism. The procedure consisted in passing a catheter through an incision and bur hole just superior to the zygomatic process of the temporal bone. The catheter was timed directly at the roof of the third ventricle and advanced until its tip would deliver injected materials (ethylcellulose and ethyl alcohol) 1.5 cm. lateral to the wall of the third ventricle. Two components of Parkinsonism were considerably reduced by the operation, namely the plastic rigidity and the pill-rolling tremor. But the patients could be easily identified as having Parkinsonism after operation, and none of them reestablished a wholly normal synergistic motor pattern. Patients with congenital athetosis and spasmodic torticollis were not helped, but good results were obtained in two with dystonia musculorum deformans and three with acquired choreiform movements.

Operative destruction of the region of the globus pallidus has been under consideration for treatment of basal ganglion disorders for approximately two decades. There have been many methods devised for the creation of the surgical defect. For a variety of reasons, including technical difficulties and high operative mortality, none of the methods advocated were widely adapted until the introduction of Cooper's method of chemopallidectomy.[1] Meyers has attempted the transventricular operative destruction, and more recently [2] he advocated the use of ultrasound localized by stereotaxic methods. Spiegel and Wycis [3] have used electrocoagulation lesions which have been stereotaxically placed in the region of the ansa lenticularis. Narabayashi and others [4] injected procaine in oil for blocking of the medial globus pallidus. The area of injection was located by stereotaxic methods. Fenelon and Thiebaut [5] attempted unilateral striopallidal intervention by use of leukotomes.

Cooper created lesions which were acceptable to him by infarction attending surgical occlusion of the anterior choroidal artery. More recently [1] he has advocated a method of destruction by the injection of alcohol or alcohol-containing vehicles in the region of the medial globus pallidus, as well as the thalamus. He has named this procedure a chemopallidectomy. Cooper's method has been the technique most widely accepted. This method, with personal modifications, has been used in 52 separate procedures for dystonia of basal ganglion origin. Forty-three of these have been for Parkinsonism;

Read before the Section on Nervous and Mental Diseases at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

two for dystonia musculorum deformans; three for choreiform movements; one for spasmodic torticollis; and three for congenital athetosis. The patients on whom these procedures were performed were followed up from 3 to 22 months.

Methods

The surgical technique used in these procedures is that described by Cooper[1] as the temporal approach for chemopallidectomy. Some personal modifications which seemed appropriate have been made. In Cooper's method pneumoencephalography is utilized to visualize the structures that are landmarks for implantation of a balloon polyethylene cannula in the region of the medial globus pallidus. For accurate placement, it is necessary that the pneumoencephalogram adequately delineate the roof of the third ventricle and the interventricular foramen (foramen of Monro). In Cooper's method 30-40 cc. of air is introduced via the lumbar route with the patient under local anesthesia.

Fourteen of the procedures in this series were done by this technique. The last 38 were done with the patient under general endotracheal anesthesia, and complete pneumoencephalography was done. In this series, an attempt was made to introduce air by ventriculography and cisternal puncture, but these procedures were abandoned in favor of the lumbar route because of inadequate filling and greater potential dangers with use of these methods. The polyethylene cannula was introduced through a small incision and a bur hole just superior to the zygomatic process of the temporal bone. In the medial direction it was aimed directly at the roof of the third ventricle and advanced until its tip was in position to deliver injected materials 1.5 cm. lateral to the wall of the third ventricle. The anteroposterior placement of the needle was 3-5 mm. posterior to the posterior lip of the intraventricular foramen. The catheter was sutured firmly to the scalp and kept in place two to three weeks. The material injected contained ethyl cellulose, 8%, and ethyl alcohol (Etopalin), 92%. Three to five injections of 0.75 cc. were made during a 15-day period. The first injection was done at operation if local anesthesia was used. If general anesthesia was used, the first injection was delayed until the patient had recovered from pneumoencephalography and general anesthesia. The position of the cannula was checked by x-ray prior to each injection. It was further checked prior to the first injection by the instillation of 0.5 cc. of 1% solution of procaine hydrochloride. If the catheter was the type which contains a small balloon at its tip, the balloon was inflated at the time of injection as a means of estimating what the effect of the alcohol will be, as well as a method of localizing the alcohol in one area. Should either of these methods fail to produce the anticipated improvement in symptoms, the position of the catheter may be changed by either advancing or retracting the tip.

The operation is first done on one side, and two to four months later it is repeated on the contralateral side. The procedure is done with the patient in the upright position. A portable x-ray machine is kept in the operating room, and frequent anteroposterior and lateral x-rays are taken throughout the procedure for accurate placement of the catheter.

In this study it was felt that general anesthesia is preferable for the procedure, as it has considerably reduced the trauma to both the patient and the surgeon. This makes possible full pneumoencephalography and more accurate delineation of the cranial landmarks. Operating time for the procedure was one to one and one-half hours. There were no wound infections in this series.

Selection of Patients

In this series of procedures there has been a change in the requirements for operability in Parkinsonism. During the first 10 procedures, the requirements were that medical treatment had been a total failure. This usually meant that the patient was bedfast, or nearly so, and unable to feed or dress himself. It soon became evident that this procedure is potentially lethal in elderly debilitated patients, as many of these patients were. This combination of age and debilitation led directly to the two fatalities which occurred during the first 10 procedures. In addition, five major fractures occurred after minimal trauma in patients who were made ambulant after having been bedfast for prolonged intervals.

It is presently recommended that the procedure should be done when the patient loses social compensation. An intense attempt at medical management is first made. If the patient is unable to maintain employment or requires help in feeding or dressing, I feel that the procedure is indicated. Experience with patients with far-advanced arteriosclerosis, periarticular fibrosis, and age greater than 65 years has been disappointing. Therefore, these factors are considered to be contraindications for the procedure. Far-advanced impairment of vocalization and swallowing also contraindicates the procedure, as these components of the syndrome are not improved by it and may, in fact, be made temporarily worse.

Results

Only two components of Parkinsonism are improved by chemopallidectomy. These are plastic rigidity and pill-rolling tremor. The symptoms secondary to plastic rigidity, such as muscle cramps, bradykinesia, easy fatigability, and retropulsion, are all improved proportionately to the reduction in rigidity. The pill-rilling tremor is reduced, but not as consistently as the rigidity. This has not been a great disadvantage to the operative procedure, since the most disabling component of the syndrome is the rigidity.

It is of interest to note that in many patients with bilateral disease who have had a unilateral operation there has been a continued and unchanged progression of the disease on the ipsilateral or unoperated side. No postoperative progression of symptomatology on the contralateral or operated side has been noted.

The bulbar components of the syndrome, which were made worse by surgery, all returned to the preoperative level, only to have progression in impairment at what appears to be the preoperative rate. This was noted in 10 patients. Flapping, pendular tremors were made worse in two patients. Two patients had spontaneous outbursts of laughing or crying which were unrelated to a feeling of sadness, and these were unchanged by the operative procedure. There have been no epileptic seizures in this series of patients.

It should be pointed out that these patients all had moderate to severe disease prior to operation, and none were made completely well by the procedure. There was considerable reduction of rigidity and tremor, to a point near 100%. Despite the reduction, the patients could easily be identified as having Parkinsonism after operation, and none of them reestablished what could be considered the normal synergistic motor pattern. For this reason, it was elected to classify the patients into the following categories: (1) 75% or more reduction in symptoms, (2) 50% reduction, (3) 25% or less reduction, and (4) no improvement at all.

Forty-three procedures were done for Parkinsonism. There were two deaths, one hemiplegia, and seven total failures insofar as relief of tremor and rigidity is concerned. Mortality for the entire series was 4%. The total failure rate with the procedure was 23%. One death was from staphylococcic pneumonia resistant to antibiotics, and the second death was from overhydration and pulmonary edema. Both deaths and three of the failures occurred in the 14 patients operated on under local anesthesia. The one hemiplegia and four other failures occurred in the 29 patients operated on under general anesthesia. Two of the last four failures occurred in patients whose disease was far-advanced and who probably should not have been subjected to the procedure. However, in this disease the surgeon frequently finds that insistence on operation by patients and pressure by the attending physician are apt to make for selection of patients who are not ideal for surgical treatment.

In those patients surviving the procedure, it was the impression that 70% had 75% reduction in rigidity; 10% had 50% reduction; and 1% had 25% reduction or less. The improvement in tremor was less impressive. Forty-eight per cent of the patients had 75% or more reduction; 16% had 50% reduction; 2.5% had 25% reduction; and 33.5% had no reduction in pill-rolling tremor. In properly selected patients, it seems likely that 90% of those operated on should have an impressive reduction in rigidity and approximately 65% should have a satisfactory reduction in tremor. Therefore, I would not hesitate to recommend this procedure to a patient whose principal impairment was plastic rigidity and in whom age and debilitation did not contraindicate the procedure.

Two procedures were done for dystonia musculorum deformans, with nearly complete reduction of the athetoid movements. One of these patients was nearly bedfast in the preoperative period. He recently passed his examination and received a driver's license in the state of Oregon. Three procedures were done for lifelong, nonprogressive athetoid movements. None of these patients were improved. One patient had a chemopallidectomy on the left side for spasmodic torticollis on the right. He was not benefited. Three patients had chemopallidectomy for acquired choreiform movements. All were greatly improved.

Summary

Fifty-three patients were subjected to chemopallidectomy for dystonia of basal ganglion origin; there was a 4% mortality and a 2% hemiplegia rate. The procedure afforded considerable reduction in plastic rigidity and tremor of Parkinsonism. The other components of the syndrome were not improved.

Good results were obtained in the treatment of dystonia musculorum deformans and acquired choreiform movements. The procedure was of no value in congenital athetosis and spasmodic torticollis.

833 S. W. 11th Ave. (5) (Dr. Paxton).

The ethyl cellulose and ethyl alcohol injection material used in this study was supplied as Etopalin through Dr. Frank A. Travis of Ciba Pharmaceutical Products, Inc., Summit, N. J.

SUBCAPSULAR NEPHRECTOMY

COMPARISON OF FIFTY-THREE CASES WITH THREE HUNDRED EIGHTY-FIVE CLASSIC NEPHRECTOMIES

Willoughby E. Kittredge, M.D.
and
John C. Fridge, M.D., New Orleans

Subcapsular nephrectomy has advantages over classic nephrectomy in certain types of renal pathology. During performance of classic nephrectomy, a number of accidents can occur. These include injuries to the vena cava or duodenum on the right side, to the stomach, spleen, or aorta on the left side, and on either side to the colon or small intestines, diaphragm, pleura, pancreas, adrenal glands, or renal pedicle. However, in subcapsular nephrectomy the thickened capsule is left attached to the peritoneum or diaphragm, and this affords protection to the contents of the chest and abdominal cavities. Because it requires less time to perform subcapsular nephrectomy than classic nephrectomy, the subcapsular approach is particularly indicated in patients considered poor surgical risks, in whom the pathological condition of the kidney would render a classic nephrectomy tedious and difficult.

In 1949, 34 cases of subcapsular nephrectomy were compared with 100 cases of classic nephrectomy performed by members of the department of urology at the Ochsner Clinic.[1] This study suggested that in indicated cases the subcapsular approach has certain advantages over the classic operation. Since that report subcapsular nephrectomy has been performed on 19 additional patients. It is the purpose of this paper to compare these 53 cases with the 385 classic nephrectomies performed during the same period to determine if the same impression still prevails.

The subcapsular method of removal of the kidney has been employed for more than half a century. Mayo[2] saw the operation performed in Tuffier's Clinic in Paris in 1900. Fourteen years later he saw Federoff perform the same operation in Petrograd by a slightly different technique.[3] Joly[4] credited Albarran with being the first to describe a method of isolating the ureter in subcapsular nephrectomy. In 1942 Lazarus[5] suggested a method for protecting the diaphragm in difficult nephrectomies which probably represented a partial subcapsular nephrectomy.

Kimbrough and Morse[6] recently emphasized the indications of subcapsular nephrectomy. This method is indicated particularly in two groups of patients. The first includes patients with chronically infected kidneys in which severe perinephritis has developed with resultant fixation to adjacent structures. In 46 of our 53 patients having subcapsular nephrectomy, the diagnosis was calculous pyonephrosis or infected hydronephrosis. The second group consists of patients who have had previous renal surgical procedures.[7] Forty per cent of our 53 patients having subcapsular nephrectomy had had previous renal operations, as constrasted with only 4% of our patients having classic nephrectomy. In these two groups of cases subcapsular nephrectomy not only is technically easier to accomplish but also affords protection to surrounding structures.

During performance of classic nephrectomy, a number of accidents can occur. These include injuries to the vena cava[8] or duodenum[9] on the right side, to the stomach, spleen, or aorta on the left side, and on either side to the colon or small intestines, diaphragm, pleura, pancreas,[10] adrenal glands, or renal pedicle. However, in subcapsular nephrectomy the thickened capsule is left attached to the peritoneum or diaphragm and this affords protection to the contents of the chest and abdominal cavities. Subcapsular nephrectomy is, of course, contraindicated in patients with renal tuberculosis or neoplasms because in such cases all involved tissue must be removed.

The technique of subcapsular nephrectomy used by us is as follows: The same lumbar Mayo incision as is used for classic nephrectomy is made. The renal fascia (Gerota's fascia) is opened as far posteriorly as possible and the kidney is exposed. If additional exposure is needed, the last rib is resected. The convex border of the kidney is exposed; no attempt is made to mobilize the entire kidney. Along the convex border an incision is made through the inflammatory capsule and the true capsule down to the renal cortex. With a finger the kidney is shelled out of its capsule down to the hilum. The capsule is circumcized around the renal

pedicle as completely as possible with a knife in order to free the pedicle for accurate ligature, after which two clamps are applied to the pedicle. The kidney is excised, care being taken to leave a temporary cuff of tissue distal to the more superficial clamp to guard against slipping of the pedicle through the clamps. After the pedicle has been secured, this excess tissue is trimmed off. The pedicle is ligated with multiple transfixion sutures of absorbable chromic surgical suture. If feasible the ureter is isolated and divided in the usual manner; otherwise, it is left alone. Sometimes it may be necessary to decapsulate only that portion of the kidney adherent to the diaphragm or peritoneum with complete extracapsular dissection of the remaining surfaces. This reduces the amount of inflammatory tissue left in the wound. Sometimes oozing from the inner surface of the remaining capsule will require packing of the wound for 48 hours. Otherwise a simple Penrose drain is used. The wound is then closed in the usual manner.

Comparison of Results

In general, the patients in our series having subcapsular nephrectomy were poorer surgical risks than those having classic nephrectomy. Thus, 38% of our patients having subcapsular nephrectomy were poor surgical risks as contrasted with only 4% of those having nephrectomy. In these patients who are poor surgical risks the subcapsular approach is usually preferable to the classic because it requires, on an average, less time than the classic operation. The average time required for performance of subcapsular nephrectomy in our series was 70 minutes, whereas for the classic technique it was 81 minutes. However, patients usually stay in the hospital a little longer after subcapsular than after classic nephrectomy. Our patients had to remain in the hospital after subcapsular nephrectomy on an average of three days longer than those having classic nephrectomy. Thus, the average duration of hospitalization in the subcapsular group was 15 days and in the classic group 12 days. The maximum duration of postoperative hospitalization for the subcapsular group was 32 days and the minimum 7 days, whereas for the classic group these figures were 47 and 6 days respectively.

Persistent drainage of the wound complicated both types of nephrectomy, but the average duration of wound drainage for the subcapsular group was considerably longer than for the classic group, being 37 days and 16 days respectively. The maximum duration of wound drainage in the subcapsular series was 153 days as contrasted with 113 days for the classic cases. Persistent purulent drainage from the wound after subcapsular nephrectomy may be due to retained infected elements, usually part of the inflammatory capsule, which will necessitate reopening the wound at a later date to remove this tissue. One patient whose wound drained for 153 days after subcapsular nephrectomy later required a second operation for removal of a calculus in the renal pelvis that had been deliberately undisturbed. However, one patient whose wound drained for 113 days after classic nephrectomy also required removal of infected tissue before the wound completely healed. The only other complication in both series was a colic fistula that developed in a patient having classic nephrectomy for extensive renal neoplasm.

The mortality for subcapsular nephrectomy was somewhat higher than for the classic cases, the incidences being 5.7 and 0.8% respectively. However, it must be remembered that the three deaths associated with subcapsular nephrectomy occurred among only 53 cases, whereas the three deaths after the classic operation occurred among 385 cases, so that it would be unfair to compare these percentages. Also, all three deaths in the subcapsular group were in elderly women. One, aged 76, died of a cerebral hemorrhage on the 17th postoperative day after an uneventful postoperative course up to that day. The second woman, aged 74, died of a septic pulmonary infarct on the 62nd postoperative day. The third patient, with myelosclerosis and advanced calculous pyonephrosis, died of postoperative collapse. Two of the three deaths in the classic group were due to pulmonary emboli, and the third was due to uremia.

Summary

Comparison of 53 cases of subcapsular nephrectomy with 385 classic nephrectomies performed during the same period by members of the department of urology at the Ochsner Clinic indicates that in two groups of cases subcapsular nephrectomy has certain advantages over classic nephrectomy. The first includes patients with chronically infected kidneys in which severe perinephritis has developed with resultant fixation to adjacent structures and the second consists of patients who have had previous operations on the kidney. Because it requires less time to perform subcapsular nephrectomy than classic nephrectomy, the subcapsular approach is particularly indicated in patients considered poor surgical risks.

CLINICAL NOTES

NEW BANDAGE SCISSORS

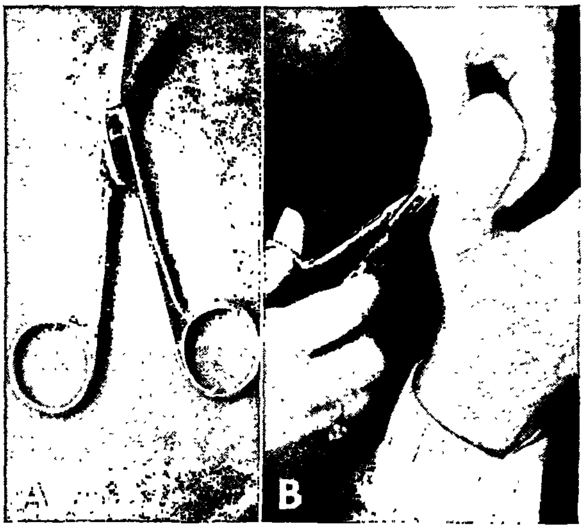
Preston J. Burnham, M.D., Salt Lake City

It has been an accepted fact for many years that bandages and tape can be safely cut away from the patient's skin only with scissors that have the point of the lower blade protected by a large acorn-shaped metal protuberance. The scissors work quite nicely when the bandage is loose; however, when a tight bandage, such as a snugly wrapped finger-bandage, is to be removed, it is a painful process to push the acorn tip between a crushed finger and its bandage. It reminds one of an ancient method of torture in which wedges were pounded beneath wrist gyves to crush the wrists.

Early in 1956, I began using the type of scissors pictured in the figure (*A*). Note that there is no acorn on the tip of the lower blade. Instead, the blade comes to a smooth, rounded point which is only slightly longer than that of the upper blade. This fact enables one to cut with the full length of both blades. The acorn-tipped scissors, on the other hand, had to be pushed far under the bandage, and cutting could be accomplished only up to within ⅜ to ½ in. of the end of the lower blade.

Another advantage of these scissors is the indentation in each limb of the handle (see figure *A*). This facilitates grasping the hub of any needle on a syringe for easy removal of the needle.

Note in the figure (*B*) that the lower blade slips easily beneath the tightest bandage. This makes for painless bandage removal for the patient and convenience for the surgeon. For two years I have used the scissors on all dressings anywhere on the body and have found that, besides slipping easily and painlessly beneath tight bandages, their short cutting action easily goes through the toughest dressings without binding. The newly designed point of the lower blade does not catch in the skin or in the dressing.



New bandage scissors: *A*, lower blade point is smooth and rounded instead of acorn-shaped, and scissors has squared indentation in each handle proximal to fulcrum to grasp needle hub. *B*, blade slips easily and painlessly under tight bandage.

WHERE ARE THE CASES OF RADIUM POISONING?

A PLEA FOR ASSISTANCE

Samuel D. Clark, M.D., Cambridge, Mass.

Is fall-out from atomic bombs dangerous to us or to our descendants? What will be the effect of 30 years' continuous exposure to strontium 90 and other radioactive materials? These questions have produced more speculations than facts. The answers may well be right in front of us if we would only look at them. We cannot afford to dally much longer. How many know that there are alive today a large number of persons who have been harboring radioactive substances within their systems for over 30 years, a full generation? These persons are generally referred to as having cases of radium poisoning—internal deposits of radium, mesothorium, radiothorium, thorium X, thorium dioxide, or any combination of these materials. Some painted watch dials, some drank "Radithor," and others had injections of radium chloride, a type of accepted therapy in 1927. Most doctors and laymen alike assume that these persons have all been dead for years. This is far from the case.

Need for Cases

While some were injured, we are reasonably certain that about 2,000 luminous dial painters from the early 1920's are still living, most of them in good health. There are probably several hundred who drank radium water or who had injections of radium salts during the period 1915-1930 who are still very much alive today, but, except for a few, we do not know who or where they are. The publicity created by the death of a few was partly responsible for the elimination of the dangers in the use of radium in more recent years.

In 1956, at the request of the Atomic Energy Commission, a committee met in Washington, D. C., to give further consideration to the problem of the biological response of man to continuous low doses of strontium 90. This committee recommended that the human radium exposure cases be restudied to see whether there was any correlation between the incidence of minimal bone changes and the incidence of bone tumors. A major problem in such a study is the finding of these radium poisoning cases of an earlier generation and making them available for study before the persons involved die from natural causes. Time is of the essence in this search. By examining human beings with 30 years' exposure to minute amounts of radiation (not laboratory animals with a few months' exposure), we can get a much clearer picture of what to expect 30 years from now.

A frustrating side of this problem is the near certainty that all the files and records of the early workers in radium have been destroyed by either accident or inadvertence. For example, the records of the investigation by the U. S. Department of Labor in 1929 were destroyed in 1944 as a routine measure. The U. S. Public Health Service reported on the hazards of the radium dial painting industry in 1933. All of the detailed information identifying personnel and plants using or producing luminous paints was lost in a flood in 1942. The files of individual investigators, such as those of the late Dr. Frederick B. Flinn of the Columbia University College of Physicians and Surgeons, have all been destroyed because their value was not recognized.

Before it is too late we must leave no stone unturned in our efforts to find and study every possible case. Doctors, nurses, and the medical records departments of hospitals, if aware of the need for finding cases of radium ingestion or injection, could be of inestimable value in locating these persons.

Radioactivity Center

In the belief that there is an urgent necessity for collecting and integrating this information and for keeping it intact, a central catalogue for recording all cases of chronic irradiation poisoning in human beings by certain internally deposited alpha emitters has been set up at the Radioactivity Center of the Massachusetts Institute of Technology. This is being done under the guidance of Prof. Robley D. Evans, with the medical supervision of myself. All available records in this field are now being microfilmed, and a punch-card system has been installed for recording data on persons with radium poisoning. This information will then be available in one location for future study and correlation of such items as the amount of internally deposited radioactivity, shortening of life span, susceptibility to other diseases, and incidence of bone changes and tumors.

The following investigators in the United States and Great Britain are collaborating with the Radioactivity Center at M. I. T. in this project: Dr. Robert J. Hasterlik of the Argonne Cancer Research Hospital, Dr. Austin M. Brues and Mr. L. D. Marinelli of Argonne National Laboratory, Mr. Lester A. Barrer of the New Jersey State Department of Health, and Prof. W. V. Mayneord of the Royal Cancer Hospital, London.

From the Radioactivity Center, Department of Physics, and the Department of Medicine, Massachusetts Institute of Technology.

Signs of Radium Poisoning

There are several conditions that should make one suspicious of radium poisoning if, as is often the case, the patient has long since forgotten his or her contact with radioactive substances. These are (1) spontaneous fractures without evidence of a neoplasm at the site of the fracture (often these patients have had repeated fractures before the etiology is discovered); (2) osteogenic sarcomas which may develop 25 or more years after exposure to radium; and (3) neoplasms of the paranasal sinuses, which may also appear many years after exposure to radium. The roentgenologist should be on the lookout for a generalized demineralization of the bones and the sclerotic appearance of the metaphysial ends of the long bones and of the skull due to multiple small infarcts. Many of the dial painters had unusual trouble with their teeth, losing them at an early age and having a long convalescence after extractions. Therefore, an edentulous female, 45 to 55 years of age, with a spontaneous fracture might well be questioned as to possible radium exposure in the past.

When to Report a Case

It is our hope that the doctor who has any knowledge or clue as to the whereabouts of any person, living or dead, who falls in the following categories will notify the Radioactivity Center, Massachusetts Institute of Technology, Cambridge 39, Mass., immediately. These categories are as follows: (1) persons who ingested radium compounds of any sort, either therapeutically or in the course of their occupation, e. g., dial painting; (2) persons who received parenteral injections of radium compounds for such conditions as arthritis, hypertension, and gout; and (3) persons who suffered exposure in the process of radium research or the manufacture of radium products, such as chemists, physicists, and laboratory assistants. (*It should be emphasized* at this time that we are not concerned with those persons who were exposed to x-rays or the application of radium in such forms as radon seeds.)

As these cases are registered, the Radioactivity Center will work in close cooperation with the physician listing them, and all contacts with these persons will be made only through the reporting physician. The specific nature of the studies, such as x-rays, body radium level estimates, and other laboratory procedures, will be decided after discussion of the particular circumstances of each individual case with the doctor. In some instances the Radioactivity Center may be able to finance all or part of these studies. In no case, however, will the existing doctor-patient relationship be jeopardized.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report. Nonproprietary terminology is used for all drugs that are mentioned; when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations.

H. D. Kautz, M.D., *Secretary.*

USE OF DRUGS IN SHOCK ACCOMPANYING MYOCARDIAL INFARCTION

Arthur Selzer, M.D.
and
David A. Rytand, M.D., San Francisco

Shock is one of the most dreaded sequels of acute myocardial infarction. Its mortality rate, estimated at about 80%, is approximately three to four times higher than the over-all mortality of acute myocardial infarction, as based on unselected series, and more than 20 times higher than some "good-risk" series. With arrhythmias and thromboembolic phenomena, it constitutes a triad of complications of myocardial infarction, the elimination of which would tremendously improve the prognosis of a single attack.

Within the past decade the therapeutic approach to shock accompanying myocardial infarction has changed from passive and symptomatic treatment to an active and vigorous use of drugs including blood volume expanders. The evaluation of such therapy and the establishment of a clear-cut policy are difficult for two reasons. In the first place, the

---

From the Department of Medicine, Stanford University School of Medicine.

causes and mechanism of this form of shock are not well understood. Secondly, the extreme seriousness of this condition precludes all but the simplest methods of objective circulatory studies. This report attempts to evaluate critically the present status of drug therapy of shock associated with acute myocardial infarction.

Nature of Shock Accompanying Myocardial Infarction

Shock may be defined as a clinical syndrome associated with a physiological state in which the circulating blood volume is disproportionately small for the size of the vascular bed. Shock thus arises when blood pressure necessary for the perfusion of important organs cannot be maintained. It is, therefore, a failure of the peripheral circulatory regulation system, and the abnormally low cardiac output characteristic of shock is ordinarily a phenomenon secondary to inadequate venous return to the heart. On the other hand, the heart may, under certain circumstances, become the principal cause of shock, in which case shock becomes primarily cardiac, or "cardiogenic" in origin. The concept of cardiogenic shock implies that the heart is incapable of maintaining adequate output for the sustenance of a reasonable blood pressure in spite of an adequate venous return.[1] There are two clinical syndromes in which this appears to be the case, pericardial tamponade and tachycardias with intolerably rapid ventricular rates. In both of these conditions the clinical picture of shock may appear, often accompanied by signs of congestive failure. In neither of these syndromes is failure of the myocardium present; in the one, a high intrapericardial pressure and, in the other, a short diastole interfere with diastolic filling of the heart and so produce critical fall in cardiac output. Massive myocardial infarction may destroy enough of the functioning myocardium as to produce sudden left ventricular failure severe enough to cause shock.

It would seem obvious that, in myocardial infarction, the peripheral factor and the cardiogenic factor may both be present and, in part, may be responsible for each other. Pain and tissue destruction in general, including myocardial infarction, are shock-producing factors by way of the peripheral mechanism. On the other hand, the inadequate coronary perfusion resulting from prolonged hypotension may bring about cardiac failure or even myocardial infarction. Shock complicating myocardial infarction could thus be considered to involve a vicious circle, wherein it would be impossible to determine the principal initiating mechanism.

The two opposing concepts of shock secondary to myocardial infarction are of considerable practical importance. If it is established that this form of shock is primarily neurogenic in origin, then the purpose of therapy would be to maintain or restore arterial pressure by the use of purely peripherally acting pressor drugs. If, on the other hand, this form of shock is entirely a manifestation of cardiac failure, then peripheral pressor effect would constitute an additional overload upon the already incompetent, overstretched heart and would be highly undesirable. In this case, drugs with cardiotonic effect would be helpful.

Both clinical and experimental studies have contributed little to the understanding of shock secondary to myocardial infarction. Circulatory measurements in even milder cases of myocardial infarction have demonstrated some elements of failure, such as lowered vital capacity, prolonged circulation time,[2] and increased venous pressure.[3] The cardiac output tends to be low in myocardial infarction,[4] with patients in shock showing, as a rule, lower values than those not in shock. These observations are, however, insufficient to establish cardiac failure as the primary cause of shock. Experimentally, cardiogenic shock has been reproduced by massive destruction of the myocardium [5] or by severe overloading of the right ventricle,[6] but shock can also be produced by peripheral mechanisms.[7]

Bedside observations in patients with acute myocardial infarction indicate that, if circulatory disturbances appear clinically in the course of acute myocardial infarction, they are likely to present themselves at first as pure cardiac failure (orthopnea, pulmonary edema, gallop rhythm, pulsus alternans, and congestive phenomena) or as pure shock (restlessness, cold perspiration, ashen cyanosis, tachycardia, and evidence of intense vasoconstriction). The combination of both syndromes is considerably less common than the appearance of either one alone; and a picture of severe cardiac failure associated with severe shock in a patient is usually a terminal event.

The variability in the clinical picture of shock presents the possibility that shock accompanying myocardial infarction may be caused by different mechanisms in different cases.[8] The following good arguments can be advanced against the theory that a single pathogenic factor causes shock in myocardial infarction: (1) the aforementioned variety of clinical patterns of shock secondary to myocardial infarction; (2) the occasional successful reversal of shock by the elimination of such diversified contributory factors as severe pain in some cases and cardiac arrhythmias in others; and (3) reports by careful observers of partial or complete relief of shock secondary to myocardial infarction by the use of agents having directly opposite actions upon the circulatory system, such as phlebotomy, on the one hand,[9] and blood transfusions, on the other,[10] or digitalis [11] and peripherally acting pressor amines.[12]

It was, therefore, suggested that the early shock which develops immediately after the initial attack may be of the nature of reflex vasomotor collapse, whereas the late shock, characterized by gradual onset and often accompanied by some evidence of cardiac failure, suggests cardiogenic mechanism.[8] Between these two "pure" forms of shock, there may be many intermediate and combined forms.

Indications for Therapy

The fall in blood pressure which frequently accompanies myocardial infarction has two effects upon the heart, the favorable effect of lowering the work of the damaged organ and the unfavorable one of reducing the perfusion pressure in the coronary circulation. The latter may be of particular importance, in that higher perfusion pressure might provide some collateral blood supply to the damaged areas. It may be assumed that the two opposite factors balance each other under ordinary circumstances. The appearance of the clinical manifestations of shock suggests that arterial pressure has fallen below the critical point of perfusion of important organs, including the heart, and that higher pressure may be necessary, regardless of its increased work load on the heart. Probably the fall in blood pressure that often follows acute myocardial infarction is, in part at least, a manifestation of a homeostatic mechanism which attempts to set the work of the heart at an optimal level. It would follow that the establishment of an arbitrary danger level of blood pressure is unsound. An expectant conservative attitude can be recommended even in the presence of systolic pressure as low as 80 mm. Hg, provided that none of the signs of shock are present, that the patient's urinary output is adequate, and that the heart rate is not unduly rapid. On the other hand, signs of shock may appear in a patient who had hypertension prior to the attack, even though the systolic pressure may be 120 mm. Hg or more; in that case, treatment may be indicated. Thus, the primary indication for treatment is the presence of clinical signs of shock. When shock is present, it is necessary to decide whether to use simple, nonspecific measures or to use antishock therapy. Nonspecific measures, including recumbency, administration of oxygen, and the use of morphine or its substitutes, sometimes correct the early shock which may be a manifestation of simple stress, apprehension, or nausea, or which may be a form of vasovagal collapse. If shock is of overwhelming severity or if it does not respond to nonspecific measures within a reasonable time, then more specific antishock therapy should be undertaken. Such therapy should be considered a major therapeutic maneuver and itself carries a definite risk.

In some cases, shock secondary to myocardial infarction may be associated with the presence of various forms of cardiac arrhythmias, which may be assumed to contribute to the state of shock. These include rapid cardiac rhythms, such as paroxysmal tachycardias, atrial flutter or fibrillation with uncontrolled ventricular rates, on the one hand, and higher degrees of heart block with slow ventricular rates, on the other. In the presence of circulatory embarrassment, even minor disturbances of rhythm, such as brief periods of bigeminal rhythm, could contribute to heart failure or shock. This is suggested by the fact that even a single premature beat can be followed by the appearance of mechanical alternation of the pulse for a period of several beats. Therefore, a serious effort should be made to eliminate arrhythmias, if possible, before antishock therapy is instituted. In those cases in which shock is associated with obvious evidences of cardiac failure, either left ventricular or combined type, treatment of failure should take precedence over antishock therapy.

Drug Therapy

Pressor Amines.—Sympathomimetic drugs with primary effect on peripheral arterioles are usually referred to as "pressor amines" and are used because of their action in increasing the systemic peripheral arteriolar resistance. Pressor effect is only one of their actions, however, and their effective use in hypotension may be overshadowed by other, undesirable actions. Thus, few of the older sympathomimetic drugs are useful for the treatment of shock. Epinephrine, the most powerful local vasoconstrictor, has a negligible effect on the peripheral vascular resistance. Its pressor effect is, in most part, due to a powerful stimulation of the myocardium and increase in cardiac output. The associated increase in myocardial irritability makes it an unsuitable drug for the treatment of myocardial infarction and cardiac failure. Ephedrine and amphetamine (Amphetamine, Benzedrine, Raphetamine) have an action similar to that of epinephrine, though slower and more sustained, and differ from the latter by being effective orally. These two drugs do not have, however, a dependable pressor effect and are used more for their bronchodilating and cerebrum-stimulating effects, respectively, although ephedrine has been used with equivocal results in the treatment of postural hypotension. Phenylephrine (Neo-Synephrine) was the first pressor amine to be used as a pressor agent during spinal anesthesia because of the predominant action on the cardiovascular system. Similar uses have been applied to hydroxyamphetamine (Paredrine). However, not until levarterenol (Levophed) became available did interest awaken in the use of pressor amines for shock occurring in cardiac patients.

Levarterenol, also known as *l*-norepinephrine, was long suspected of being the adrenergic nerve mediator, since it has been isolated from adrenal medullary extracts. The separation of pure levarterenol from racemic arterenols in 1948 supported the hypothesis of its physiological function and provided a basis for the study of its pharmacodynamic action, which eventually led to its clinical application in the treatment of hypotensive states. Studies by Goldenberg and co-workers[13] have shown that levarterenol administered as a continuous intravenous infusion increases the systemic blood pressure without increasing the cardiac output, therefore significantly raising peripheral resistance. In addition, levarterenol causes significant capillary and venous constriction. It has, furthermore, a direct stimulating effect upon myocardial contractility in the dog.[14] The question as to whether levarterenol enhances undesirable cardiac arrhythmias, a by-product of the myocardium-stimulating effects of drugs, is still a subject of controversy. Experimental evidence supports, as a whole, the view that the severe arrhythmogenic effect of epinephrine is matched by that of levarterenol.[15] Clinical studies suggest, on the other hand, that therapeutic doses of levarterenol do not frequently precipitate arrhythmias, although some investigators stress the importance of such dangerous complications.[16]

The action of levarterenol in increasing the peripheral resistance in human beings is amply demonstrated, both in normal individuals and in patients with shock.[17] This action makes it admirably suitable in normovolemic and hypervolemic forms of shock.[17a] Levarterenol has been used extensively in shock secondary to acute myocardial infarction.[18] The results of all the earlier studies were interpreted as showing that it has a beneficial effect on shock of myocardial infarction, both in restoring a more normal arterial pressure and in reducing the over-all mortality rate. A significant pressor effect was observed in the majority of cases. The effect upon the mortality rate showed a wide variation, with its reduction to 14% in one small series [19] and with relatively little reduction in others. Recently, reports have appeared denying any beneficial effect whatsoever of levarterenol in shock secondary to myocardial infarction.[20]

A critical evaluation of the effect of levarterenol on cardiogenic shock is rather difficult in view of the contradictory results. The difficulty is, in part, due to the lack of uniformity in defining the state of shock that follows myocardial infarction. The wide range of responses to therapy suggests that different types of patients were treated and compared with each other. Furthermore, the theoretical indications for therapy with levarterenol are not entirely clear. Those investigators who regard shock as a disturbance of the vasomotor mechanism use levarterenol primarily for its peripheral action of increasing arteriolar resistance. Those who believe that shock of myocardial infarction is cardiogenic regard any success from use of levarterenol as largely caused by direct myocardial action.[19] The latter view is based on two observations: (1) the use of levarterenol in patients who exhibited shock and cardiac failure, in whom signs of pulmonary edema and congestive phenomena improved; and (2) the failure to note such an improvement in similar patients treated with phenylephrine, which has a purely peripheral vasomotor effect.[19] These studies bring out the only positive arguments for the existence, in human beings, of a direct myocardium-stimulating effect of levarterenol. Yet these arguments are not entirely acceptable as evidence for such a cardiac effect of the drug. First, improvement of cardiac function could be effected by a pressor effect of the drug, resulting in improvement of coronary perfusion, and, second, the comparison between phenylephrine and levarterenol has been based on a series far too small to permit definite conclusions to be drawn.

Another important and undecided question is the optimal time for the administration of levarterenol. Some workers [18c] stress the importance of an early start of antishock therapy, suggesting that a delay of the onset of treatment for over three hours sharply limits the success and increases the mortality. Yet, if one is to treat shock within the first two hours of its onset, one is sure to include many cases of simple vasomotor collapse which could clear without specific therapy, therefore exaggerating the apparent success of the group treated earlier.

The principal advantage of levarterenol in the treatment of shock lies in its ease of administration. The drug, given by continuous intravenous drip, can take effect within a minute or two and can be instantly withdrawn if it is no longer needed. The pressor effect can easily be titrated by the speed of the infusion or by the concentration of the drug in the solution. Its disadvantage is the local vasoconstrictive effect, which may lead to serious tissue necrosis if extravasation of the drug occurs.

In recent years several other pressor amines have been introduced for the treatment of shock. The three drugs investigated for their effect on shock secondary to myocardial infarction are mephentermine (Wyamine), methoxamine (Vasoxyl), and metaraminol (Aramine).

In experimental animals, mephentermine shows an action similar to that of levarterenol by exhibiting a pressor effect caused by increase in systemic arteriolar resistance and a myocardial-stimulating action. In human beings, it has been used in shock accompanying myocardial infarction, with moderate success.[21] After intramuscular injection a pressor effect lasting up to four hours can be observed, with no significant increase in arrhythmias in the cases studied.

Methoxamine differs from mephentermine and levarterenol in that it shows, in experimental animals, a pure peripheral pressor effect, without exhibiting any myocardial effect. Experimental studies suggest a significantly lower tendency to produce arrhythmias. It is effective by the intramuscular route in intermittent doses.

Metaraminol combines a strong pressor effect with a myocardial-stimulating action in experimental studies.[22] Its clinical use is similar to that of levarterenol except for the absence of tissue-irritating action; therefore, the drug can be administered both by continuous intravenous drip and by repeated intramuscular injections.[23] Clinical trials of metaraminol for the treatment of shock associated with myocardial infarction showed results comparable to those of levarterenol.

Antiarrhythmic Drugs.—The appearance of disturbances of cardiac rhythm is common in acute myocardial infarction. If arrhythmias and shock appear together secondarily to myocardial infarction, it is reasonable to assume that the arrhythmia is contributing to the circulatory disturbance and that the elimination of the arrhythmia may be beneficial to the patient. As mentioned, the most serious types of arrhythmia are those associated with a very rapid or a very slow ventricular rate, such as rapid atrial and ventricular tachycardias, uncontrolled atrial flutter and fibrillation, complete heart block, and slow pulse rates due to bigeminal rhythm with ineffective premature beats.

The drug of choice for the control of atrial flutter and fibrillation is digitalis, because the immediate objective is to slow the ventricular rate before a further attempt is made to convert the arrhythmia to sinus mechanism. Shock associated with rapid atrial flutter and fibrillation is one of the few incontestable indications for the intravenous use of digitalis, preferably a rapid-acting digitalis preparation such as ouabain or the glycosides of Digitalis lanata. Digitalis may be used in atrial and nodal tachycardias but is ordinarily contraindicated in ventricular tachycardia.

Quinidine may be effective in controlling all forms of ectopic paroxysmal tachycardias and ectopic beats. Its use in restoring sinus rhythm in atrial flutter and fibrillation should follow digitalization which is effective enough to control the ventricular rate. Quinidine, however, exerts a depressant action upon the myocardium and requires caution when used in myocardial infarction. The parenteral use of quinidine in such cases should be considered a calculated risk in situations in which safer measures are ineffective or the urgency is extreme.

Procainamide (Pronestyl) has a specific effect in terminating and preventing ventricular arrhythmias. It has been used extensively in paroxysmal ventricular tachycardia both orally and intravenously, but whether it is more effective and safer than quinidine has not been definitely established. It has a depressant effect upon the heart and systemic blood pressure similar to that of quinidine.

The acceleration of the slow idioventricular pacemaker in complete heart block can be attempted in two ways. Occasionally, higher degrees of heart block may be caused by increased vagal activity, in which case atropine may be effective. More often, heart block is caused by direct depression or destruction of the conducting tissues. In such cases, the use of those sympathomimetic drugs that have a strong inotropic effect is indicated, namely, ephedrine, epinephrine in oil, isoproterenol (Aludrine, Isonorin, Isuprel, Norisodrine), and phenylpropanolamine (Propadrine). The drug most widely used of late is isoproterenol, which is effective parenterally and sublingually.

Parasympathomimetic drugs, including choline esters and cholinesterase inhibitors such as methacholine (Mecholyl) or neostigmine, may be used either alone or in conjunction with carotid sinus pressure to attempt to terminate paroxysmal supraventricular tachycardia. Potassium salts are used occasionally in shock secondary to myocardial infarction, in the presence of an arrhythmia which may have been caused by a toxic dose of digitalis.

Measures Used To Control Cardiac Failure.—The presence of left ventricular failure or of failure of the left and right sides of the heart is an indication for the use of conventional means of therapy of heart failure. Patients who have previously not had digitalis should be given the full therapeutic dose of the drug, preferably of a rapidly acting preparation; however, this procedure requires more caution than in cardiac failure not associated with myocardial infarction because of the hazard of inducing ventricular tachycardia in the latter condition. Salt restriction is an important part of the therapy of cardiac failure and may be, if necessary, supplemented by the use of diuretic agents.

Other Therapeutic Agents.—The administration of oxygen is widely used in myocardial infarction, particularly when complicated by shock. The physiological rationale for such therapy is questionable because, even in severe shock, the arterial blood is fully saturated, and cyanosis, when present, is caused by peripheral stasis and higher utilization of oxygen in tissues because of the low cardiac output. Oxygen inhalation can supersaturate the arterial blood by its physical solution in plasma. Whether this small additional amount plays a role in overcoming the possible tissue anoxia in the myocardium and other organs is not known. However, in the absence of pulmonary disease, oxygen administration is entirely safe, and its use can be justified empirically.

Pain-relieving agents are of considerable importance because they may be extremely effective in those cases in which vasomotor collapse is caused by ischemic myocardial pain. However, almost all pain-relieving drugs also have a hypotensive effect and in sensitive individuals may lead to nausea, which in itself is a shock-producing agent. Such drugs should be used, therefore, with caution, and the supervision of the patient during their action is essential.

Blood volume expanders formerly enjoyed a brief period of popularity,[10] but later they were largely replaced by pressor amines. Such methods included intravenous infusion of plasma or blood and the intra-arterial administration of blood. The results of these therapeutic maneuvers were equivocal regarding the over-all mortality of shock secondary to myocardial infarction, although temporary favorable effects upon blood pressure levels have been frequently observed.

Comment

The rational approach to the therapy of shock accompanying myocardial infarction is hampered by the inadequate knowledge of the underlying pathophysiology of this type of shock. The prevailing controversy regarding the mechanism of shock centers around the initial factor responsible for the state of shock.

This controversy regarding the factors responsible for shock poses a practical problem of therapy, as to whether peripherally acting or cardiotonic drugs should be employed. The variability of the clinical picture makes interpretation of the results exceedingly difficult. In spite of the widespread interest in the use of pressor amines, which undoubtedly are holding first place in the treatment of this syndrome, enthusiasm of some observers has to be balanced by denial of others that the drugs have any beneficial effect on this condition. The area of uncertainty involves two points: (1) whether the difference demonstrated in animal experiments between pure pressor amines (phenylephrine and methoxamine) and pressor amines with associated cardiotonic action (levarterenol, mephentermine, and metaraminol) can also be demonstrated reliably in the therapeutic range of use in patients, so as to justify the separate pharmacological classification of these drugs; and (2) whether the direct myocardial effect of some of these drugs, if significant, is an asset or a liability in their use in myocardial infarction. Neither of these questions can be answered authoritatively at the present time. The difference between levarterenol and phenylephrine has been studied in a few cases, which, as pointed out, does not constitute a valid argument. It should be noted that there is a similarity between the action of levarterenol, a combined pressor and cardiotonic drug, and the effect of blood volume expanders. However, levarterenol has replaced the latter, largely because of the ease of administration. Blood transfusions, which can relieve shock but have no cardiotonic effect, appear to be less effective in the shock accompanying myocardial infarction than is levarterenol; yet the difference between the two forms of therapy is not striking and could be accounted for by a more effective regulation of dose. The question of desirability of a cardiotonic action of a pressor amine hinges on the basic mechanism of shock accompanying myocardial infarction, as already discussed. It is generally agreed that a drug with a significant cardiotonic effect has, as a by-product, a tendency to increase myocardial irritability, which is particularly undesirable in myocardial infarction wherein the threshold for dangerous arrhythmias is low. It is believed that the answers to these questions might become available from a carefully organized comparative study, which would investigate the effect of four agents on clinically similar cases of shock secondary to myocardial infarction, namely, (1) pure cardiotonic drugs (digitalis); (2) combined cardiotonic pressor drugs (levarterenol, mephentermine, metaraminol); (3) pure pressor drugs (phenylephrine, methoxamine); and (4) blood volume expanders.

Summary

Shock accompanying acute myocardial infarction is subject to controversy concerning its cause and mechanism. It is suggested that this complication of myocardial infarction cannot be explained on the basis of a single mechanism but rather should be considered a clinical syndrome caused by peripheral vasomotor factors in some instances, by cardiac failure due to intolerable overload of the infarcted ventricle in others, and by inefficient cardiac function caused by arrhythmias in still other cases. At present, because of the unsatisfactory state of understanding of this syndrome, it appears preferable to treat the factor which clinically dominates the picture rather than to formulate a single therapeutic regimen applicable to all cases of shock secondary to myocardial infarction.

Therapeutic measures effective against surgical and other forms of peripheral shock have been applied to treatment of shock secondary to myocardial infarction. These include the use of blood or plasma transfusions given intravenously, intra-arterial blood infusions, and the administration of various pressor amines. All such measures have restored effective blood pressure in many cases, although it is not definitely demonstrated that the high mortality rate from this form of shock has been effectively reduced.

Pressor amines, which at present are considered the treatment of choice for shock, fall into two groups according to their actions in animal experiments, those with purely peripheral vasoconstrictor action and those with combined peripheral and cardiotonic action. It is not yet known whether, in human shock, the difference between the two groups is of practical importance or whether one or the other groups of drugs is superior in the treatment of shock secondary to myocardial infarction.

Shock accompanying myocardial infarction remains an exceedingly serious complication with a very high mortality rate. In spite of considerable enthusiasm concerning the effectiveness of new drugs, there are those who deny that specific antishock measures have any beneficial effects whatsoever.

This study was supported by a grant from the American Heart Association.

COUNCIL ON FOODS AND NUTRITION

The Council has authorized publication of the following announcement. These fellowships are sponsored by the Nutrition Foundation, Inc., in cooperation with the Council. In 1959, 10 fellowships will be given in honor of Dr. Virgil P. Sydenstricker, recipient of the 1958 Joseph Goldberger award in Clinical Nutrition.

PHILIP L. WHITE, SC.D., *Secretary.*

FELLOWSHIPS FOR RESEARCH IN CLINICAL NUTRITION

PURPOSE: To stimulate staff members and students of schools of medicine to take a more active interest in the science of nutrition.

AMOUNT: $200 per month for three months.

CONDITIONS: 1. Grant shall be made to a medical student on recommendation of a senior investigator. 2. Recipient will be selected by the Council. 3. Grant shall be used solely for remuneration of selected medical student. 4. Grant shall be limited to a period not to exceed three months during the nonacademic portion of school year. 5. No senior investigator may have more than one student per year receiving a grant. 6. Only a brief progress report or summary will be required. Publication will be at the discretion of the senior investigator.

APPLICATION: 1. Application should be made in writing by the senior investigator to: Council on Foods and Nutrition, American Medical Association, 535 N. Dearborn St., Chicago 10, on or before Dec. 15, 1958. 2. Application shall include: (*a*) brief outline of study proposed, (*b*) assurance that adequate physical facilities are available, (*c*) assurance (but not necessarily identification) of the availability of a qualified medical student.

Fall-out and Protection

There is a great need for better fact-finding and evaluation of world-wide radioactive fall-out, according to Willard F. Libby, Ph.D., a member of the U. S. Atomic Energy Commission. Lacking adequate statistical tools, he adds, existing evidence indicates that biological effects of a nuclear war would be serious and deadly but would "not constitute an overwhelming medical problem."

Dr. Libby's comments appear in prepared remarks scheduled for delivery next Thursday (Oct. 16) in Madison, Wis., before a symposium sponsored by the A. M. A. Committee on Foods and Nutrition. He makes these additional points:

—With better statistics we could estimate the world-wide hazard from nuclear war fall-out and could exercise more efficient control over the consequences.

—A national fall-out shelter program is an absolute necessity "for the defense posture of this country."

(See Pages 772 and 773 for items from the recent Boston meeting of the A. M. A. Committee on Civil Defense.)

Conferees listen to Dr. Joseph A. Falzone, National Institutes of Health, Gerontology Branch, Baltimore, as he spoke on "Basic Medical Research" at A. M. A. Planning Conference on Aging.

Conference Calls for Medical Society Action in Aging—"Medicine's No. 1 Problem"

Millions of people in this country face special problems of health and well-being as they grow old—problems which also influence the lives of their neighbors in every age group. What are these problems? What is American medicine doing to help solve them?

In Chicago last month, 150 representatives from 46 states—including medical society designates, state health commissioners, and members of agencies concerned with the multiple phases of aging and the aged—gathered at an A. M. A. Planning Conference. The purpose of the meeting Sept. 13 and 14 was "to develop effective responses to the growing challenges in aging which face medicine and to coordinate present and future medical society acticities at national, state, and local levels."

It was the first in a series of conferences sponsored by the Council on Medical Service's Committee on Aging. Future sessions, also under A. M. A. auspices, will separately feature representatives of insurance companies, nursing homes, federal agencies, and other groups whose contributions and aims in the field of aging might be brought together in a program of integrated action. A joint conference to crystallize the efforts and direction of all interested groups then will be held, probably early next year, according to Dr. Joseph D. McCarthy of Omaha, the Council chairman. He said: "Time does not stand still today. We cannot say to ourselves, 'these problems can be answered tomorrow.' If we fail to plan and to do our part now, we may have no chance tomorrow."

The planning conference, which was many months in preparation, took place during a period when reports from wide and varied sources were outlining a new surge of interest and concern for masses of population considered "old." Sample reports noted that:

—A special meeting of the Federal Council on Aging was being held (scheduled for Sept. 30) to review federal-state relationships. After referring to the meeting, Mr. Sidney Spector, of the Council on State Governments, told the A. M. A. planning conference: "The oldsters of this nation are ready now to exert the massive political control to which their numerical proportion has been building." One-fourth of the U. S. electorate is now 65 years or older, and their number is growing at twice the rate of the over-all national population.

—Congress had passed legislation calling for a White House Conference on the Aging in January of 1961—preceded by federally-financed conferences at the state level. Many of the state conferences would be held in 1960, a Presidential election year. A special staff from the U. S. Department of Health, Education, and Welfare was gathering data this month in preparation for the state conferences.

—In Oslo, Norway, an 11-nation advisory group for the United Nations' World Health Organization was recommending a series of studies on problems arising from the growing number of aged—covering such aspects as retirement and employment, nutrition, housing, fitness, and health education.

—With the help of a Ford Foundation grant, the 250-member National Committee on the Aging (of the National Social Welfare Assembly) was launching a project to survey relatively unexplored ground: *the extent and possible needs relating to* legal protection and guardianship for oldsters. The study is being conducted in cooperation with bar associations and banking firms. Other committee projects cover research, employment, housing.

These events expose only the visible ripples in a deep sea of complexity engulfing elderly people and their intertwining social, economic, and health problems. That is why the A. M. A. at its planning conference was emphasizing the basic strength potential of individual physicians and their medical societies (three-fourths of the state medical associations and scores of county societies have committees on aging)—to point up community effort as the key to solution of a gigantic national problem. That also is why not one, but four, large organizations in the health field are tackling the problem. This is the recently-created Joint Council to Improve the Health Care of the Aged, whose members represent the American Dental Association, the American Hospital Association, the American Nursing Home Association, and the A. M. A.

All four associations recognize that, at a time when his medical needs normally are greatest, the earning power of the typical oldster is at its lowest. Multiplied by the millions, it is this factor—more than any other—which challenges the entire community in every corner of the nation.

Selected Comments

The problem in its complexity, the challenge in its urgency, and the future in its opportunity are illustrated in the following selected comments made at the Chicago conference (an editorial on the meeting is published on page 779 of this issue of THE JOURNAL):

The A. M. A. Committee on Aging is headed by Dr. Frederick C. Swartz of Lansing, Mich. Other members are Drs. Theodore G. Klumpp of New York; Wingate M. Johnson of Winston Salem, N. C.; Cecil Wittson of Omaha; David B. Allman of Atlantic City; Edward L. Bortz of Philadelphia; Henry A. Holle of Austin, Tex.; and Henry B. Mulholland of Charlottesville, Va. Staff secretary is Mr. George W. Cooley.

Physician's Share of Public Costs for Indigent Care

A recent government report should debunk once and for all the idea that physicians receive the lion's share of public funds spent for health care of the indigent. The opposite is true—in most public assistance health programs, doctors' services represent the smallest cost item, according to the Department of Health, Education and Welfare.

An analysis of the HEW report, made this month by the A. M. A. Committee on Indigent Care, reveals that of the total 287 million dollars reported for indigent health costs last year, less than 13% was paid to physicians. Over five times as much was spent for hospitalization. Almost as much was spent for drugs and supplies as for physicians' services. In all types of public assistance programs—for the disabled, the aged, dependent children, and general aid—hospitalization was the largest health cost item. Physicians' services was the smallest in every category except aid to dependent children, where it comprised 25% of total health costs.

"This report should be of particular interest," said a spokesman for the A. M. A. Committee, "because the physician frequently has been blamed for the cost of such services, although these may include hospital and nursing home costs, eyeglasses and other appliances, and even dental care. Now the unjustness of the blame is documented. The basic fault lies with the lumping together of all indigent health services under the catch-all heading of 'medical care.'"

Dr. Louis M. Orr, A. M. A. President-elect—"Medicine and its related fields have been largely responsible for extending longevity. Therefore medicine and its related fields have a responsibility of doing all they can toward solving any problems which they themselves have helped to generate."

Dr. David B. Allman, immediate past President of the A. M. A. and a member of the Committee—"There is no more important issue before American medicine today than the problems of the aging and the aged" (Medicine at Work, THE JOURNAL, July 27, 1957).

Dr. Theodore G. Klumpp, a Committee member and president of Winthrop Laboratories—"Decline will proceed more slowly (after the prime of life is reached) if the bodily functions are fully employed and, through moderate stress, they are held to their maximum capacities. . . . We must do everything we can, as we grow older, to resist the inclination to slow down the tempo of our living."

Dr. LeRoy Burney, surgeon general of the U. S. Public Health Service—"Joint action by the medical and health professions has made possible the elimination of many scourges of man. At the same time, these successful measures have opened the door to the most complex and provocative health problem of an aging population—chronic illness."

Dr. Wingate M. Johnson, a Committee member and professor of clinical medicine at the Bowman-Gray School of Medicine, Winston-Salem, N. C.—"Perhaps the most important challenge to the medical profession is to train its own members in the care of the older patient. This training should begin while they are medical students. . . . The family doctor has a peculiar advantage in being able to see the viewpoints of both the older and younger generation and to talk frankly to both."

Dr. Cecil Wittson, a Committee member and chairman of the Department of Neurology and Psychiatry at the Nebraska Psychiatric Institute, University of Nebraska College of Medicine—"There is a very impelling personal reason for the physician's participation in the community solution of the problems of aging. He is proverbially conscious about the health of his patients, but notoriously reckless with his own. But geriattrition is the common fate of man. For once, the healthy future you are attempting to guarantee is not the other fellow's. It is your own."

Dr. Jack Weinberg, clinical associate professor of psychiatry at the University of Illinois—"Aging begins when an individual stops adapting. . . . We Americans are so busy planning for the future that when it becomes the present we cannot enjoy it because we are thinking about the future."

Dr. Edward L. Bortz, a Committee member and chief of Medical Service Staff "B" at Lankenau Hospital, Philadelphia—"With one hand society is extending the life of man, with the other it is writing him off because of the date on his birth certificate. . . . If the 65 age barrier is not eliminated, many citizens face an extended senescence which could reach the proportion of a national calamity."

Exhibit and Workshops

Workshop sessions which followed presentations by individual speakers at the planning conference evoked recommendations which included these:

"People should be willing to pay for local services for the aged as for police and fire protection."

"Home care programs and homemaker services should be expanded."

"Physicians should not dominate the team effort."

"How about a central revolving fund from which loans could be made to oldsters for medical care?"

"Medicine has got to help the people evaluate nursing home care."

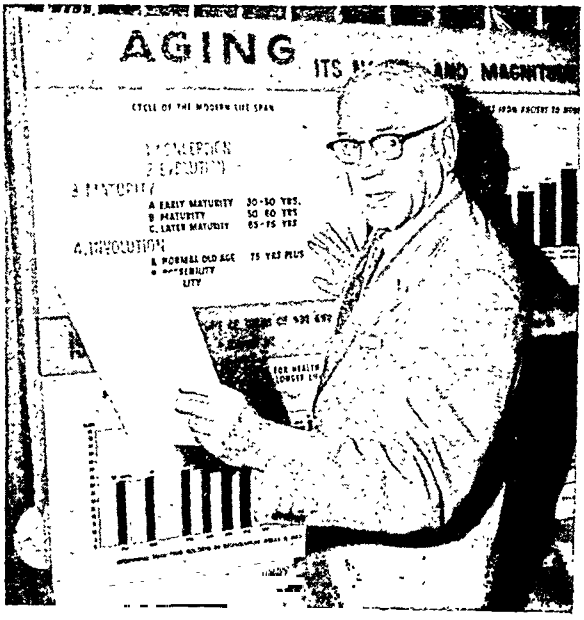
Between sessions, participants previewed, for the first time, a new exhibit to be introduced at the A. M. A. Clinical Meeting in Minneapolis Dec. 2-5. It illustrates the following six objectives of the Committee on Aging:

1. To seek public acceptance of a proper perspective toward older citizens.
2. To promote health maintenance and restorative services.
3. To encourage the training of personnel and the development of facilities for the care of the aged.
4. To cooperate in developing community programs for senior citizens.
5. To expand medical and socioeconomic research in reference to aging and the aged.
6. To improve methods of financing health care for the aged.

Beyond the Conference

Those aims form the framework of last month's planning sessions. But they do more than that—they delineate the broad areas of a continuing campaign which the medical profession, along with other groups, is pursuing on a long-range basis in order to better the health of the entire nation. For, in referring to our aging population, the conferees last month underlined one salient fact: It is too easy to fall into the error of considering these millions of elderly people as a group apart from the rest of society. Each of us is aging, from the moment of birth—really, from the instant of conception.

As Dr. Frederick C. Swartz, the Committee chairman, expresses that point: "It is not the aim of the Committee to break the human family up into groups because of some definable differences, such as age—but, rather, to keep the unit together by placing emphasis on their similarities. Medicine offers a positive health program which emphasizes physical exercise, intellectual activity and mental equanimity as a blueprint to continued good health. This whole program is health oriented, not disease impelled."



AGING
ITS … AND MAGNITUDE
CYCLE OF THE MODERN LIFE SPAN
A EARLY MATURITY 30-50 YRS.
B MATURITY 50 60 YRS
C. LATER MATURITY 65-75 YRS
A NORMAL OLD AGE 75 YRS PLUS
FOR HEALTH

Dr. Edward L. Bortz, a member of the Committee on Aging, demonstrates the new exhibit which the Committee will show at the A. M. A. Clinical Meeting in Minneapolis.

Reports Show Regional Variation in Disaster Emergency Planning

Distinct variations in the condition of medical disaster and defense planning efforts of eight Northeastern states were indicated by reports at a regional meeting held by the A. M. A.'s Committee on Civil Defense in Boston Sept. 13.

The Committee, one of two under the Council on National Defense, holds semiannual meetings in regions of the Office of Civil and Defense Mobilization. These sessions enable state medical societies and their woman's auxiliaries to report on local plans and problems.

State reports ranged all the way from Maine's elaborate organizational complex involving practically all of the state's health and medical groups to a New Jersey doctor's charge that disaster planning in his state is not supported by the state government.

Dr. Clyde I. Swett, representing the Maine Medical Association, outlined in detail efforts in his state to incorporate all health and medical agencies into both the planning and execution phases of disaster organization. "Each medical and paramedical section is charged with setting its own training plans, but the work is directed by an advisory council whose members are recruited from all health fields," he said.

Dr. R. Winfield Betts, chairman of the Special Committee on Civil Defense–Disaster Control of the Medical Society of New Jersey, reported the state is unwilling to enforce the New Jersey Civil Defense law, because it is politically unpopular. "Civil defense is a government responsibility," Dr. Betts said. "The government must develop the organization and make it work." He said his committee was anxious to assist the state director of civil defense training but was unable to get any action.

Different View From Vermont

Taking a different view was Dr. William Worthington, director of Medical Care Services for Vermont. He said he felt that lack of interest or organization by governmental units can be overcome. He said: "Once people are sold on emergency planning, no matter how distasteful the subject may be, they will force adequate federal and state planning to meet the situation." Mr. Getty Page, executive secretary of the Vermont State Medical Association, said his group was "about to come up with a good plan." The association, he said, had a good plan in the past, but it dissipated through lack of use and changes in personnel.

"Poor organization of emergency planning at state levels can usually be attributed to a lack of conviction that 'something can be done.'"

This is the opinion of Dr. Harold C. Lueth, chairman of the A. M. A. Committee on Civil Defense. He says: "The idea of the H-bomb numbs people into inactivity. We must emphasize that, while emergency care is an everyday part of medicine, its application in times of both war and natural disasters will be haphazard without an adequate plan."

Dr. Lueth feels that organized medicine must take the initiative in such planning, not wait for governmental units which may be reluctant to outline duties for professional groups.

A difference of opinion on the state of medical preparedness for defense and disaster in Massachusetts was shown in reports from its representatives. Dr. Robert W. Buck, secretary of the Massachusetts Medical Society, characterized the Bay State's situation as one of "confusion." He said an organizational plan had been laid out on paper, but the state society had produced "no action" on civil defense. This view was disputed by Mrs. John Crowley, chairman of the Committee on Civil Defense of the Woman's Auxiliary. "I think we have a good civil defense set-up," she said. "In my area (Lynn), each physician knows his post for an alert."

Dr. Harold C. Lueth of Evanston, Ill. is Chairman of the A. M. A. Committee on Civil Defense. Other members are Drs. Cortez F. Enloe Jr. of New York; Carroll P. Hungate of Kansas City; Max L. Lichter of Melvindale, Mich.; David Henry Poer of Atlanta, Ga.; Roscoe L. Sensenich of South Bend, Ind.; and Charles W. Steele of Lewiston, Maine. Mr. Frank Barton of Chicago is Staff Secretary.

New York, too, has had its share of confusion in civil defense efforts, according to Dr. Edward A. Burkhardt, chairman of the Special Committee on Civil Defense and Catastrophe. But he felt the state had "come a long way" in many aspects. "New York has government-supplied 200-bed civil defense emergency hospital units and stockpiled medical supplies," he said, "but we need concentrated effort and an annual check on the assignment of physicians to stations." The medical association's role, he said, should be to outline a sound medical program and present it to the state government.

Progress in Rhode Island

Rhode Island's progress in medical civil defense has been satisfactory, Dr. James B. Moran, chairman of the state association's Committee on Disaster, told the group. He said: "Atomic and disaster emergency plans have been instituted in hospitals. We have done some work with the CD-supplied packaged emergency hospital unit (Organization Section, The Journal, June 22, 1957) and are convinced each unit needs a trained civilian crew to set it up."

Counteract Mock Alert Shortages with Variety of Substitutions

Conditions simulated during Operation Alert 1958 in New England, New York, and New Jersey indicated shortages "so tremendous they could not possibly be met from resources within the region." That is what Dr. Jacob H. Landes, regional medical officer, told the A. M. A. Committee on Civil Defense last month in Boston.

Dr. Landes said that had the emergency been real, rather than an exercise, the following measures would have been necessary:

—Considerable stocks of sulfonamides would have been pressed into service to replace penicillin and broad-spectrum antibiotics.

—New sulfonylureas would be substituted for insulin for adult diabetics and insulin supplies reserved for children.

—Barbiturates and sedatives would be recommended to replace narcotics.

—Linen supplies in retail stores, textile houses, hotels, and laundries could be frozen and requisitioned for conversion into surgical pads and dressings.

—Training programs for self-help medical care would be organized to relieve the shortage of professional personnel.

—Expansion of existing hospital facilities to three or four times their normal patient load would be attempted, as well as the discharge of noncritical patients.

Evaluate Task Force Material in Emergency Medical Care Study

"Millions of casualties" and perhaps as much as 60% of the nation's skilled health and medical personnel dead or incapacitated . . .

This is the problem on which Dr. Earle Standlee, Staff Director of the A. M. A. Commission on a National Emergency Medical Care Plan, is basing the Commission's plan of study to establish criteria for the provision of medical care of the surviving population.

Speaking at the regional meeting of the A. M. A. Committee on Civil Defense in Boston recently, Dr. Standlee said the Commission is currently evaluating and classifying information prepared by three Task Forces established last April. Membership in these Task Forces was recruited from national health and medical organization which would be directly involved in the management and care of mass casualties in the event of enemy attack.

The Commission was created in April, 1957, by the A. M. A. Board of Trustees to develop a plan under a contract with the Office of Civil and Defense Mobilization (formerly FCDA).

Doctors Report on Alert Tests

In an effort to promote medical participation in disaster preparedness tests, the program of the Ninth Annual County Medical Societies Civil Defense Conference to be held in Chicago Nov. 8-9 will feature reports on several field test operations conducted this year. These will include:

Test Exercise Star—based on a mock earthquake of severe intensity, and conducted by the Alameda Contra Costa (California) Medical Association in cooperation with civil and military authorities.

Operation Prep Pitt—dealing with a theoretical jet plane crash into the Pitt Fieldhouse, and sponsored by the Allegheny County (Pennsylvania) Medical Society with the cooperation of local authorities.

Operation AFTA—based on a simulated plane crash on the Tulane University campus, and conducted by the Committee on Medical Education for National Defense (MEND) of the Tulane School for Medicine.

CD Ideas at Workshop Sessions

Workshop sessions held at the recent Boston meeting of the A. M. A.'s Committee on Civil Defense produced several ideas. Suggestions advanced:

—Scale models of the government-issued 200-bed civil defense emergency hospitals, to be used as an aid in training.

—Use of armed forces reserve units in tests of disaster plans.

—Urging of physicians to become well informed on radiological problems so that they may instruct patients on such matters as the handling of food, water and sanitation.

—Role of the Woman's Auxiliary as teachers in home survival care.

How Contagious Is Mental Illness?

A relatively unexplored concept—the communicability of mental and emotional illness—will come up for group discussion next month in Chicago as a highlight of the Fifth Annual Conference of Mental Health Representatives of the State Medical Associations.

Scheduled as chairman of this discussion in Chicago on Nov. 21 is Dr. Walter Baer of Peoria, a member of the A. M. A. Council on Mental Health, which is sponsoring the two-day meeting. Other round-table groups will consider mental illness and health in the aged, education for psychiatric medicine, the Joint Commission on Mental Illness and Health, and mental retardation in school children. Dr. Leo H. Bartemeier of Baltimore, Chairman of the Council, will preside at plenary sessions. Guest speakers will include A. M. A. President Gunnar Gundersen and Jonas E. Salk.

Safety in Sports— A Milestone and a Program

As the football season pushes into full swing this month on campuses across the nation, physicians could note an all-but-forgotten golden anniversary of an occasion which does great credit to the game and to their profession.

It was exactly 50 years ago that Dr. Edward H. Nicols, a physician at Harvard University, braved outraged cries of the school's football players by requiring them to wear headgear, braced shoes, thigh guards, and collarbone and shoulder pads. This was unheard of, never done before. Yet, only two years earlier, in 1906, sports enthusiast Theodore Roosevelt had called a White House conference of representatives from Harvard, Yale, and Princeton, in a move to transform the game from brutal roughhouse into clean and fast play.

Dr. Nicols recognized that the outcome of the conference—introduction of the forward pass and some other modification of rules—produced a safer game. But it wasn't safe enough—19 concussions on the Harvard squad in a single year. With introduction of his protective football paraphernalia a half-century ago (only three concussions at Harvard that first year) the game rose in prestige, although it still is one of the most hazardous of body contact sports. For the first time this season, some college teams will be using new type helmets (developed with the help of physicians at Cornell University and other research centers) which promise to further reduce that hazard.

The concern displayed by Dr. Nicols for the health of his school's team is shown manifold today by thousands of physicians the country over. They are doing something about the injuries which have killed at least 1,000 youths in all sports, and injured tens of thousands more, since record-keeping of these casualties began on a broad scale 25 years ago. What are the doctors doing? They are serving as team physicians, coaches, medical advisors for schools and on school boards. They are serving as design consultants to sporting equipment manufacturers. They are in (and on) the field and in the laboratory, conducting studies in athletic injury.

Most significantly, they are working with many experts outside of medicine—trainers, dieticians, educators, coaches, and others—who also are dedicated to making athletics more of a body-building asset and less of a body-breaking liability.

Chairman of the A. M. A. Committee on Injury in Sports is Dr. Allan J. Ryan of Meriden, Conn. Other members are Drs. Carl Badgley of Ann Arbor, Mich.; Francis C. Grant of Philadelphia; George Hammond of Boston; Harold Muller of Berkeley, Calif.; Owen B. Murphy of Lexington, Ky.; Thomas B. Quigley of Boston; and Augustus Thorndike of Cambridge, Mass. Staff secretary of the Committee is Fred V. Hein, Ph.D.

A. M. A. Forms Committee

So concerned has the medical profession been with raising these thresholds of safety in competition that four years ago the American Medical Association's Board of Trustees created a Committee on Injury in Sports to determine what causes specific athletic hurts, when they occur, and what can be done about them. This summer, the eight-man committee, headed by Dr. Allan J. Ryan of Meriden, Conn., joined with the National Collegiate Athletic Association and the National Association of Intercollegiate Athletics in presenting a four-point "Bill of Rights for the College Athlete." The document (The Journal, page 2087, Aug. 23, 1958), now being distributed to universities and colleges throughout the United States, enunciates the principles of good coaching, good officiating, good equipment and facilities, and good medical care as they relate to each other in benefiting the athlete.

"So far as most schools are concerned, this Bill of Rights is not new—it has been observed in every region of the country in some form or other for many years," Dr. Ryan, a one-time collegiate distance runner, said last week. "What the statement does set down, however, is a synchronization which, we feel, will make these principles uniform. And, while these concepts relate to college sports, they are applicable to the high school, other amateur, and professional athlete as well.

"The Committee, really, has just begun to explore this broad field. Our program also calls for looking into the value of conditioning in various sports. We are concerned, too, with the large number of ankle and knee injuries occurring in all contact athletics. We are studying specific bodily hazards in skiing, boxing, skin diving [papers on these topics will appear in future issues of The Journal], auto racing, hockey, soccer, baseball, and other forms of sport. While we hope to improve methods of treatment and rehabilitation for the injured athlete, our highest priority goal is to prevent injuries.

Other Programs

The A. M. A. Committee headed by Dr. Ryan may be taking the lead for the profession but it does not, by any means, represent the only medical endeavor to benefit athletes:

—In at least half the states of this country, medical advisory committees whose members are drawn from hospital staffs, local health departments, and medical societies are working with high school athletic associations to handle injury problems, develop preventive measures, and establish physical examination programs.

—High school sports injury conferences are being held regularly under the auspices of state and county medical associations. One such athletic in-

Amphetamines, Athletes, and Performance

How effective, if at all, are the amphetamines ("pep pills") in athletic performance? How widespread is their use by athletes? What is their potential for bodily harm? How addictive are they?

These and related questions are being explored by a special A. M. A. Committee on Amphetamines and Athletes, in cooperation with university and high school athletic associations. The committee, created by the Board of Trustees last year at the direction of the A. M. A. House of Delegates, is now processing replies from a survey conducted early this year at approximately 600 colleges and 800 high schools. Also being studied are notes of interviews with coaches, team physicians, trainers, key officials, and others connected with professional, college, and high school sports. These include the commissioners of professional associations for football, hockey, basketball, and baseball.

While this questioning was going on, the special committee and its staff launched two separate studies to learn whether alleged stimulation of athletes from amphetamine drugs was real or imagined. And if the stimulation were real, was it psychological or physiological in nature?

These and related answers are not yet known. In fact, they will not be determined until the committee submits its findings to the House of Delegates in December. In developing its report, the special Committee on Amphetamines and Athletes is breaking new ground. For, while there have been a number of studies along general lines (including evaluations of pep pill use by Japanese, British, and American flight crews during World War II), none have been definitive enough for the medical goal as pursued by the Committee.

Some of these reports have been conflicting, confusing, and shallowly sensational. For example, it has been said: "Amphetamines overcome fatigue but do not stimulate." "They definitely do stimulate—the four-minute mile would not have been possible without them." "They don't do a thing but fool the athlete into believing he can do better." "They are employed as psychological weapons only, to demoralize members of an opposing team." "They are addictive." "There has been no evidence of addiction."

The controversy over pep pills is not confined to the United States. It is keeping doctors and athletes talking in Japan, Germany, Mexico, Sweden, and other nations. In England, Sir Adolphe Abrahams not long ago told the Society for the Study of Addiction: "If it were practicable to construct a tunnel with oxygen-enriched atmosphere in which runners competed, record performances would be accomplished. But would this be approved? If amphetamine and cortisone can directly release another reserve of energy, are they not to be accepted as contributing to normal physiological well-being?" His statement is open to attack on the ground of sportsmanship—particularly in amateur athletics. The statement also emphasizes the use, rather than the abuse, of amphetamine. Yet, is even judicious use safe? And if it is, what are the perils of misuse? That is what the British Association of Sport has been asked to help determine. For in England, as in the United States, the use of amphetamines in sports is officially condemned by athletic associations.

In less than two months, physicians at last should be able to see the first scientific portrayal, via an official A. M. A. committee report, of the extent of amphetamine use in sports—and how, or whether, this drug relates to health, ethics, and performance.

---

jury clinic in Santa Ana, Calif., recently attracted 50 coaches from 15 high schools and junior colleges. Similar high interest is indicated in such a conference set for Nov. 7 in Milwaukee under auspices of the State Medical Society of Wisconsin, in cooperation with other medical groups, educators, and the Wisconsin State High School Coaches' Association.

—Postgraduate courses in sports injury problems are becoming more and more popular with practicing physicians. In the past year, for example, such courses in Colorado and Oregon brought attendances of more than 200 doctors each.

—In several regions of the country, most recently in Texas, organizations of athletic team physicians are relating those groups to activities of local medical societies. Similar collaborations are occurring on a broader level, as witness cooperative studies of the International Federation of Sports Medicine with the World Health Organization.

Efforts within the profession to promote the health of the athlete are matched by activities outside of medicine. These include an ongoing study of injuries in Army athletics, a current NCAA survey of football injuries in selected colleges, and recent establishment of a four-year college curriculum for the preparation of qualified trainers—all aimed at keeping the sportsman in peak condition.

Today, six surgeons, six physiotherapists, a dietician, a radiologist, and numerous coaches and trainers are serving at Harvard—to name only one school having a sports medicine program. It is a far and progressive cry from the days of Dr. Nicols when he insisted on protective gear for Harvard football players 50 years ago. It is an even farther cry from the days of Claudius Galen, the first team doctor in history, who tended the gladiators in 200 A. D.

These milestones mark a growing medical interest in athletics and athletes. They form a backdrop to the program now being joined by doctors everywhere as more and more people, participating in sports of all kinds, face the good health along with the occasional hazard of physical contest.

Expanding Challenge Told by Rural Health Advisors

Dr. F. S. Crockett's expressed fear that the A. M. A. Council on Rural Health might have reached a plateau in its operational curve was quickly dispelled when the executive committee met with its lay advisory committee Sept. 5 in Chicago. Dr. Crockett is Chairman of the Council. His plea to the advisory groups' representatives for the sort of program they could "go to bat for" brought immediate results.

Ten representatives of national farm, educational, research, and publishing organizations came to the meeting primed with suggestions as to areas of work and investigation that might bear fruit in the field of rural health.

Similarity of interest on the part of many of the advisory groups represented was apparent in several areas: nutrition; hospital facilities and insurance plans; the possible transference of antibiotics and hormones in food from milk, poultry, and meat animals to humans; and the need for leadership and medical cooperation in rural health efforts.

Mr. Beatty H. Dimit, chairman of the Interim Health Committee of the National Grange, said the Grange feared most that the rising cost of hospital care might "destroy Blue Cross." The Grange, he said, would like to see the Council investigate deductibility features in hospital insurance policies.

The widespread inclusion of hospital insurance as a fringe benefit in labor contracts has resulted in such overloading that hospitalization has become increasingly difficult for some patients, according to Mr. Herbert J. Voorhees, chairman of the Health Committee of the American Farm Bureau Federation. One of the big jobs ahead, Voorhees said, is to find funds for additional construction.

Expressing concern, too, over pyramiding costs of hospital construction and operation was Mr. Paul C. Johnson, editor of *The Prairie Farmer* and vice-president of the Board of Trustees of Lutheran Deaconess Hospital in Chicago. He said: "A hospital must be an efficiently operating unit, like a big factory, before savings can be accomplished. People have expensive tastes in medical care."

Dr. Martin P. Hines, a veterinarian from Raleigh, N. C., thought the Council should look into the question of whether antibiotics, especially penicillin as used to control mastitis in cows, might not be making the "entire population" penicillin-sensitive. Richard C. Davids, editor of *The Farm Journal*, agreed that the possible overuse of antibiotics was "one of the big questions" of farmers.

While agreeing that continued work on nutrition was important in rural health, Johnson felt that new approaches are necessary. Johnson said that future campaigns, in addition to plugging a theme such as "Better Breakfasts," would have to place greater emphasis on changed living patterns.

"We have to keep in mind that many people just don't wake up hungry," he said. "To them, breakfast is just those few minutes between dressing and leaving for work."

Chairman of the A. M. A.'s Council on Rural Health is Dr. F. S. Crockett of West Lafayette, Ind. Dr. Carll S. Mundy of Toledo, Ohio, is Vice-chairman, and Dr. George M. Fister of Ogden, Utah, is liaison member from the Board of Trustees.

Regional directors and the states they represent include Dr. Mundy (Michigan, Missouri, Ohio, Indiana, and Illinois), Dr. Fred A. Humphrey of Fort Collins, Colo. (New Mexico, Colorado, Utah, Montana, and Wyoming), Dr. Norman H. Gardner of East Hampton, Conn. (Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Rhode Island, Delaware, New York, New Jersey, and Pennsylvania), Dr. Willard A. Wright of Williston, N. D. (North Dakota, South Dakota, Iowa, Nebraska, Wisconsin, and Minnesota), Dr. Allen T. Stewart of Lubbock, Texas (Oklahoma, Kansas, and Texas), Dr. W. J. Weese of Ontario, Ore. (Idaho, Washington, and Oregon), Dr. Charles R. Henry of Little Rock, Ark. (Florida, Georgia, Alabama, Mississippi, Louisiana, and Arkansas), Dr. Carroll B. Andrews of Sonoma, Calif. (California, Arizona, and Nevada), and Dr. W. Wyan Washburn of Boiling Springs, N. C. (Maryland, West Virginia, North Carolina, South Carolina, Kentucky, Tennessee, and Virginia).

Secretary of the Council is Mrs. Arline Hibbard.

Need for Leadership

The need for greater leadership by state and county medical societies in rural health programs was expressed by several of the advisory groups' representatives when they met recently with the executive committee of the Council on Rural Health in Chicago.

"Our women are good health representatives," Mrs. Mason G. Lawson, Chairman of the By-Laws Committee of the A. M. A. Auxiliary, told the group, "but we sometimes feel the lack of a place in the program. We rely on the medical societies for guidance and advice and we need more leadership."

Warning of the possibility of government interference "if we don't do it ourselves," Mr. Herbert J. Voorhees of the American Farm Bureau Federation said, "We need more intraprofessional urging of cooperation on rural health programs. I feel the A. M. A. has not sold rural health programs to the state societies."

As an answer to the need for leadership, Mrs. Lawson suggested the advisory committee theory be extended to local levels in rural health work as an operational device.

Doctors and Communities Rated in Alabama Placement Survey

Communities and doctors seeking each other (Medicine at Work, The Journal, Sept. 29, 1956) in the perennial problem of physician placement are finding the way made easier for them in at least one state, thanks to a "community medical rating" survey conducted by the Medical Association of the State of Alabama.

With this study, the State Association aims to do more than just place a doctor in a town. Helping the community to evaluate itself and learn to keep a physician once he arrives is one major objective. Providing resource material for prospective physicians is another. The first was planned for in the booklet "Your Town—Weighed in the Balance." The second is being fulfilled by the accumulation of community information on equipped medical facilities, new industries, churches, and schools not previously listed in placement service files.

So far, Texas and Alabama are the only states reporting use of a Community Rating Schedule which was developed in 1953 by the A. M. A.'s Committee on Medical and Related Facilities. The schedule rates "individual need priorities" of communities and "desirability priorities" of physicians.

The survey committee sent medical questionnaires to town clerks in 301 municipalities with populations of 25,000 or less, with the cooperation of the Alabama League of Municipalities. If no response was received, the questionnaire was sent to the local chamber of commerce. The Alabama Academy of General Practice distributed a similar questionnaire to a member in each county. These mailings brought responses from one or more towns in 62 of the state's 67 counties.

With the reports tabulated, committee members made pilot studies of three communities. They sent letters of explanation to the communities and county societies and applied the Community Rating Schedule at meetings with local representatives. Then, with the initial studies completed, the committee visited other communities—38 in all, in 24 counties. Two of these towns had secured physicians within a month. The committee visits and evaluates each new community added to the placement service files. Reports are made available, on completion of each study, to interested physicians.

Neither Alabama, nor Texas, which made a similar study (*J. A. M. A.* 157:365-366 [Jan. 22] 1955), harbor doubts as to the value of their efforts. The Alabama report on the work says in part:

"If nothing else were accomplished . . . the time, money, and effort involved were justified in enhancing the relationship and prestige of the medical profession in Alabama with these communities."

Profession as "Matchmaker"

Where do most doctors have their hearts set on practicing?

California, Illinois, and New York.

Where is the greatest demand for physicians?

Illinois, North Carolina, Wisconsin, and Minnesota—listing over 100 opportunities each.

Where are the forces of doctor demand and supply likely to first meet in a courtship which weds a doctor to a community?

A. M. A. headquarters in Chicago.

These facts stand out in a report this month by the A. M. A. Committee on Medical and Related Facilities, which oversees activities of the Physicians Placement Service. Working through state medical societies, the A. M. A. office in the past year served as go-between for nearly 2,000 physicians and 1,700 communities trying to get together. Most of these physicians had recently completed an internship or residency; the others were just out of military service or were trying to relocate. Many of the communities were—and are—seeking better medical care for their citizens.

How does the medical profession play the matchmaker? It makes its placement services known through exhibits at medical student meetings, announcements to community leaders, and leaflets and listings to the profession. Many doctors express their preferences by mail and in person to Chicago—last year nearly 300 of them, some traveling cross-country, came directly to the A. M. A. office (under the Council on Medical Service) to gain a picture of location opportunities. But, in almost all cases, it is the state medical association placement service which brings the community and the doctor together after the A. M. A. "clearinghouse" initiates introduction.

(A detailed annual report of the A. M. A. Physicians Placement Service is scheduled for publication in The Journal on Oct. 25, 1958.)

FLASH BLINDNESS AND CHORIORETINAL BURNS PRODUCED BY ATOMIC FLASH

GUEST EDITORIAL

Brig. Gen. Victor A. Byrnes (MC), U. S. A. F.

TWO separate, though related, conditions may be produced by atomic flash. One is flash blindness, a temporary incapacitation produced by visible light, and the other is retinal burn, produced by a combination of visible and infrared light. Their implications from a disaster standpoint are quite different.

Flash blindness is due to the bleaching of the retinal photosensitive chemicals by bright light. The duration of the incapacitation produced depends on the brightness of the items one must see after the flash is over. Hence in daylight this is not a serious problem. The pupils will be smaller and will admit only 1/50th as much light as at night and the visual task will ordinarily be much brighter. There may be a temporary scotoma in the field of vision but unless a burn is produced it will disappear and it is not visually incapacitating. At night visual disability will exist up to half an hour if the source of illumination of the visual task is a moonless sky. Any increase in brightness of the visual task will reduce the disability time proportionately. The blink reflex is of little value in protection against flash blindness because of the extreme intensity of the light. The exact effect in any individual case will depend on the brightness to which the eye is exposed (whether looking toward the fireball or away), the reflectance of surfaces, and protection afforded by buildings, overhanging structures, hats, or protective filters. The reflectance of the background and of the atmosphere varies so much that distances at which flash blindness can be expected will vary tremendously. With nominal bombs at night in the open with the subject facing the direction of the detonation it can be expected at distances of over 35 miles.

Effective filters to prevent flash blindness usually also prevent the individual from doing anything useful. This is true except for special filters designed with sharp cutoffs to permit certain specialized visual tasks utilizing narrow bands of monochromatic light. If a period of warning is given the individual can cover both eyes to prevent both flash blindness and retinal burns. If he must see during the warning period a patch may be worn over one eye to protect the retinal adaptation in that eye even though the uncovered one is dazzled by the flash. The patch may then be placed over the eye with flash blindness so it can adapt and be protected in the event of a second flash later while the previously protected eye is used for seeing.

The effect of flash blindness on implementation of civil defense planning will depend on adequate warning and on the success with which knowledge of the condition has been previously imparted to civil defense personnel.

Chorioretinal burns are a related phenomenon. Their production depends on the lens system of the eye forming an image of the fireball on the retina. The visible and near infrared light (400-1,250 mμ) energy is absorbed by the retinal and choroidal pigment. The distance to which these can be produced depends on pupillary size, clarity of the atmosphere, and size of the bomb. They can be produced by a nominal bomb to distances over 35 miles when the air is clear. Again, so much energy is delivered before the blink reflex that it is not effective in preventing this lesion. Pupillary size is important, thus making this much more of a nighttime than daytime hazard. The direction of the visual axes is much more important than point of focus. While the latter has some effect on the area of the retinal image it is not significant in attenuating the energy per unit area in it. Unless the image of the fireball is formed on the macular area the permanent effect will be a scotoma in the peripheral field similar to that of the physiological blind spot. It differs in that it will be in the same position in both eyes, thus giving a true symmetrical binocular scotoma. This will not ordinarily be a serious visual defect. However, if it is imaged on the macula bilaterally this will result in a permanent central scotoma with vision reduced to 20/200 (peripheral acuity). This lesion can occur outside the danger zone of any other atomic effect except fall-out.

Director of Professional Services, Office of the Surgeon General.

Neither of these conditions requires civil defense planning for treatment. Recovery from flash blindness will take place in about half an hour. If the energy is high enough to produce a burn it is not painful, since the retina has no pain endings, and it requires no dressing. In severe burns it may be desirable to use steroids to reduce the inflammatory reaction and subsequent scarring of the retina but no emergency treatment is required. The temporary effect of flash blindness is probably a much greater hazard to effective civil defense action than is the permanent burn.

Civil defense efforts in regard to these conditions should be directed toward education to prevent flash blindness in at least one eye and the understanding that if it does occur normal vision will return shortly. Such understanding may be helpful in the prevention of panic.

CONFERENCE ON AGING

The recent Planning Conference on Medical Society Action in the Field of Aging may well have marked a stride forward by American medicine in its continuing efforts on behalf of the nation's aging population. As reported in the "Medicine at Work" section on page 769 in this issue of The Journal, the conference was attended by representatives from 46 state medical associations. This broad representation and the enthusiasm of the group discussions alike demonstrated the growing concern of America's doctors with the problems of the aging population. Again and again, three points were made clear by both speakers and discussants: that society can not isolate the aged, that medicine must provide leadership, and that coordinated action of all groups concerned is needed.

Anyone familiar with the growth of the problems and their various manifestations must recognize the need for a new and realistic attitude toward aging and the value of concerted action. Dr. Frederick C. Swartz, chairman of the Committee on Aging of the Council on Medical Service, well stated the need for full recognition of the other two concepts.

"It is not our aim," he said, "to break up the human family into groups because of some definable differences, such as age, but, rather, to keep the unit together by placing emphasis on their similarities.

"Above all," he continued, "the American Medical Association needs leadership in this field. Not only at the national level, but at the level of the states and counties. A type of leadership that binds medicine together and confidently points the way for all who would live long and happily. . . . Leadership that realizes that there is more to the practice of medicine than seeing patients, that composite ills or areas of possible improvement are also the responsibility of the doctor."

ORALLY AND PARENTERALLY ADMINISTERED RADIUM

Important in the list of iatrogenic diseases are the abnormalities of bone, especially sarcoma, that appear many years after the internal administration of radium.[1] Radium salts were given orally and intravenously in the treatment of numerous medical disorders during the period 1915-1930.[2] Their use seemed to be justified by the state of medical knowledge at the time.[3]

It is now evident that the late effects of internally deposited radioactive materials can be extremely grave, and they are of increasing concern to radiologists. A pilot study on patients who received thorium dioxide injections from 1930 to 1945 was started in Washington in 1955.[2] As was noted by Looney and Colodzin, hundreds of patients who have had radioactive materials in their bodies for long periods of time are still living. They are excellent sources of material for defining more precisely the safe levels of radioelements in the body.

It must not be assumed that everyone who has received radium or thorium internally will develop bone tumors, blood dyscrasias, or other diseases. If the familiar *post hoc, ergo propter hoc* fallacy is to be avoided, there must be comparisons between groups with and without lesions attributable to ionizing radiation. The almost limitless resources of university and government laboratories are available for the processing of the information so obtained; they include such facilities as low-background chambers for the examination of persons with low body-content of radium and new apparatus for the quick examination of teeth extracted by dentists. But the *sine qua non* is patients, with and without lesions attributable to radium, in sufficient numbers to permit meaningful comparisons between groups.

Attention is therefore directed to the appeal of Dr. Samuel D. Clark, elsewhere in this issue (page 761) of The Journal, for the cooperation of American physicians in a study of the late effects of radium poisoning. This study represents a cooperative effort of the Radioactivity Center of the Department of Physics at the Massachusetts Institute of Technology and the Division of Biology and Medicine of the Atomic Energy Commission. Competing on the one hand with roentgen rays and on the other hand with the radioactive isotopes produced by the uranium pile, radium seems to be nearing the end of its period of usefulness in therapy. Physicians cooperating in this study of its late effects can help to write the close of one of the most dramatic chapters in the history of medicine.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

Second Session, 85th Congress

Construction

S. 3914, by Senator Thye (R., Minn.), pertains to the Hill-Burton Act extension and would authorize a $2,500,000 appropriation for grants to states to survey the need for renovation and modernization of public and nonprofit hospitals, diagnostic or treatment centers, rehabilitation facilities, and nursing homes. In its application, a state would have to designate a single agency which would utilize the services of the state Hill-Burton advisory council in making the survey and report to the surgeon general all information required by him. The funds would be allotted by a formula provided in the bill, but no allotment would be less than $25,000.

The bill also authorizes 50 million dollars for the fiscal year 1959 and 100 million dollars for each of the two succeeding years to be used as grants for the renovation and modernization of the above facilities. A formula for allotting funds to states is provided, but no state would receive less than $300,000.

The bill provides that, after passage, the surgeon general, with the approval of the Federal Hospital Council and the Secretary of the Department of Health, Education, and Welfare (HEW), would revise and supplement the regulations and equipment and general standards of priority for projects to be renovated and modernized. After such regulations have been issued, the states would be required to amend their state plans so as to qualify for the grants. The bill also provides for a five-year extension (through June 30, 1964) of both the regular hospital construction provisions and the categorical programs.

H. R. 12628, by Representative Williams (D., Miss.), would extend the Hill-Burton Hospital Construction Act. It provides for a five-year extension, until June 30, 1964, of both the regular hospital construction provisions and the categorical programs under the Hill-Burton Hospital Construction Act. This bill has now been passed and is Public Law 85-664.

H. R. 12694, by Representative Williams (D., Miss.), would authorize loans for the construction of hospitals and other medical facilities under the Hospital Survey and Construction Act. This bill has also been passed and is Public Law 85-589. This bill was introduced by the Chairman of the Health Subcommittee of the House Committee on Interstate and Foreign Commerce at the request of representatives of the Baptist Church which, because of its belief in separation of church and state, has not, until this year, availed itself of the grant program under the Hill-Burton Hospital Construction Act.

The bill provides for direct loans up to 40 years for the construction of hospitals and categorical facilities for which grants are provided under the Hill-Burton Act. The loans would bear an interest rate of 2.125%. The bill calls for interest equal to the current average yield on all outstanding marketable obligations of the United States plus 0.25%. The amount of the loan would be limited to the federal share of the estimated cost of construction of the projects. If the projects were being financed by both a loan and a grant, the aggregate amount could not exceed the federal share. If prior to repayment of the loan the project is transferred to a nonqualified operator or ceases to be nonprofit, the loan would become due immediately under the provisions of the bill. New funds are not authorized by the bill to carry out this loan program. Hill-Burton funds therefore would be used either for grants or loans.

H. R. 12752, H. R. 12753, H. R. 12754, H. R. 12755, and H. R. 12756, by Representatives Rains (D., Ala.), Addonizio (D., N. J.), Barrett (D., Pa.), Sullivan (D., Mo.), and Ashley (D., Ohio), respectively, would amend the Housing Act to increase the amount available for housing loans to educational institutions and hospitals and to authorize loans for building classrooms and other academic facilities.

Authorization would be increased for direct loans for college housing from the present 925 million to 1,425 million dollars. Of this sum, 125 million dollars, an increase of 100 million dollars, would be earmarked for loans to public and nonprofit teaching hospitals for the construction of nurses' and interns' housing.

The bill also provides for a direct loan program of 500 million dollars to provide 50-year loans at a maximum interest rate of 2.75% for the construction of classrooms, laboratories, and related facilities at educational institutions "offering at least a two-year program acceptable for full credit toward a baccalaureate degree." Loans could also be made for the rehabilitation or improvement of existing structures.

S. 4035, by Senator Sparkman (D., Ala.), would amend Housing Act relating loans to nursing homes. This bill provides extensive amendments to the housing laws. Two of the titles are of interest to

---

From the Washington Office of the American Medical Association.

medicine. One amendment would authorize the Federal Housing Administration to insure mortgages for the construction or rehabilitation of proprietary nursing homes. The loans could be made up to $12,500,000 or 75% of the value of the completed property, whichever is less, and bear interest at 4.5%. The mortgagor would also be required to pay 0.5% insurance premium on the loan. The federal housing commissioner would be authorized to require any mortgagor to be regulated or restricted as to charges and methods of operation. If the mortgagor is a corporate entity he could regulate or restrict its capital structure and rate of return. In the latter case, in order to carry out this authority, the commissioner would be authorized to purchase stock or interest in the mortgagor, up to $100. Such interest could be redeemed by the mortgagor on the termination of the loan.

A nursing home is defined as "a facility which is or will be licensed or regulated by law, which provides continuous medical and nursing care to the long-term, convalescent, infirm, or elderly patient in a home-like atmosphere, furnishing facilities and comforts normally found in a patient's home, and which provides, in addition thereto, such specialized services, equipment, and safety features as may be required for the safe, proper and adequate care of patients at all times." In carrying out the provisions of the loan program to proprietary nursing homes, the federal housing commissioner would be required to consult and obtain the advice and recommendation of the Public Health Service.

The bill would also authorize an increase of 400 million dollars (to 1,325 million dollars) for making direct loans for college housing. Of the total authorization, 75 million dollars, an increase of 50 million dollars, would be earmarked for direct loans to hospitals for the construction of nurses' and interns' housing.

The bill also authorizes 250 million dollars for direct loans to educational institutions "offering at least a two-year program acceptable for full credit toward a baccalaureate degree" for the construction of classrooms, laboratories, and related facilities, including equipment, machinery, and utilities.

This bill was passed by the Senate, however, it failed to pass in the House under suspension of rules. A two-thirds majority is necessary, and the bill received 251 affirmative votes and 134 negative. The American Medical Association testified in favor of the nursing home loans provisions.

H. R. 13495, by Representative Herlong (D., Fla.), would provide special Hill-Burton hospitalization construction grants for federally impacted areas. This bill would provide 15 million dollars a year for four years, beginning July 1, 1958, to be used as grants to the states for the construction of hospitals in federally impacted areas. While the program would be operated under the regular Hill-Burton program, funds would be segregated into a special account, and the federal share would be 90% of the federal impact portion of the project. If the funds provided to carry out the terms of this bill were insufficient to finance all projects eligible under the bill, the surgeon general would be required to establish a system of priorities for each project.

The "federal impact portion" is defined as the percentage of the project equal to the percentage of the population attributable to a federal impact. "Federal impact" would be determined by the increase over the previous five years in the number of federally-connected persons residing in the area. To qualify as a federally impacted area, at least 30% of the population of a county or political subdivision would have to be federally connected, and during the five-year period preceding the application, the number of federally-connected persons would have to have increased by not less than 150%. A "federally-connected person" is defined as a person or his dependents employed on federal property, except members of the armed forces and their dependents. "Federal property" is land owned or leased by the United States and which is not subject to taxation by the state; it includes Indian lands and flying schools that provide flight training to members of the Air Force. It does not include, among other things, postoffices and low-rent housing projects or any other federal property not included under the federal aid to education in federally impacted area laws.

This bill was introduced in an attempt to secure funds for hospitals in the Cape Canaveral area which has experienced a tremendous population growth (from 19.000 to 90 000 persons), the major portion of which consists of federal employees.

Public Health Service

H. R. 12668, by Representative Huddleston (D., Ala.); H. R. 12685, by Representative Multer (D., N. Y.); H. R. 12821, by Representative Broomfield (R., Mich.); and S. 4076, by Senator Barrett (R., Wyo.), pertain to Cystic Fibrosis Research and are identical to H. R. 12331, by Representative Knutson (D., Minn.), discussed in The Journal, Aug. 23, 1958 issue, page 2085.

H. R. 12784, by Representative Osmers (R., N. J.), is identical to H. R. 6747, by Representative Harris (D., Ark.), and S. 1895, by Senator Hill (D., Ala.) and others. This bill is fashioned after a law enacted in 1954 which provides a method of establishing safe tolerances for residues of pesticide chemicals on raw agricultural commodities. It would prohibit the use of additives which have not been adequately tested to establish their safety, requiring chemical manufacturers to furnish to the Federal Drug Administration evidence that proposed uses of chemical food additives would be safe. It would exempt from pretesting those chemical additives now in use that are "generally recognized" as being safe but would not exempt those not "generally recognized" as safe regardless of the length of time they have been in use. The bill would also require that additives which may be toxic when used in excessive amounts must have safe levels of use established and must have "functional value."

H. R. 12875, by Representative Williams (D., Miss.), and H. R. 12876, by Representative Roberts (D., Ala.), would extend and amend the Health Research Facilities Act of 1956. This bill would extend the 30 million dollar a year grants-in-aid program for health research facilities for an additional three years (through June 30, 1962). This bill has passed both houses and is awaiting the President's signature.

H. R. 13254, by Representative Williams (D., Miss.), pertains to chemical food additives and is similar to H. R. 6747, by Representative Harris (D., Ark.), and S. 1895, by Senator Hill (D., Ala.), and would amend the Federal Food, Drug, and Cosmetic Act to prohibit the use of additives in food which have not been adequately tested to establish their safety.

The procedure of this bill is to define a food additive and to establish a procedure whereby the safety of such additive may be established before its use. A "food additive" is defined as "any substance, the intended use of which results . . . in its becoming a component or otherwise affecting the characteristic of any food, including any substance intended for the use in producing or manufacturing, packing, processing, preparing, treating, packaging, transporting, or holding food; including any source of ionizing radiation intended for any such use, if such substance is not generally recognized . . . to be safe." Exempted from such definition is a pesticide to be used on raw agricultural commodities. The term "safe" is defined to mean "without hazard to the health of man or animal." The bill would hold that all food additives would be deemed to be unsafe unless their use conforms to the terms of an exemption or regulation issued by the Secretary of the HEW.

The bill provides for a procedure for obtaining a regulation from the Secretary of the HEW setting forth the limits of use and for appeals to the U. S. Circuit Court of Appeals from an adverse ruling of the Secretary. Experts would be selected by the National Academy of Sciences. Within 60 days of such referral, the Committee would certify its report and recommendations to the Secretary setting forth the reasons for the recommendations.

H. R. 13517 and H. R. 12834, by Representative McCarthy (D., Minn.), and H. R. 12871, by Representative Kean (R., N. J.), pertain to Maternal and Child Health and Welfare and are similar to S. 3504, by Senator Neuberger (D., Ore.), discussed in THE JOURNAL, July 19, 1958, page 1520. This bill would increase the annual authorization for appropriations for maternal and child health care from $16,500,000 to $21,500,000 and increase the authorization for appropriations for hospital and medical care for crippled children from 15 million to 20 million dollars. It would also increase the annual appropriation for child welfare services from 12 million to 17 million dollars.

S. 4193, by Senator Hill (D., Ala.) and Senator Smith (R., N. J.), is similar to H. R. 13254, by Representative Williams (D., Miss.), and would amend the Federal Food, Drug, and Cosmetic Act to prohibit the use of additives in food which have not been adequately tested to establish their safety. While the language of this bill differs from that of H. R. 13254, the purposes of both are essentially the same. The major difference is that S. 4193 eliminates the provision of an advisory committee of experts which would hear appeals from adverse rulings by the Secretary of the HEW. H. R. 13254 was reported, on July 28, by the House Interstate and Foreign Commerce Committee of containing identical language to S. 4193.

H. R. 13524, by Representative McCarthy (D., Minn.), pertains to White House Conference on Aging and is identical to H. R. 9822 by Representative Fogarty (D., R. I.) discussed in THE JOURNAL March 15, 1958, page 1338.

S. 3694, by Senator Watkins (R., Utah) anc others, pertains to sanitation facilities for Indian and is identical to H. R. 12100, by Representativ Rhodes (R., Ariz.), as reported in THE JOURNAI Aug. 23, 1958, page 2085. The bill has passed th House and on Aug. 14 has been favorably reporte in Senate.

Labor

H. R. 13507, by Representative Teller (D., N. Y.) pertaining to welfare and pension plans disclosur is similar to H. R. 13223, by Representative Roosevelt (D., Calif.), and S. 2888, by Senator Douglas (D., Ill.) and others, S. 3044, by Senator Mundt, and H. R. 10102, by Representative Berry (Republicans, S. D.), S. 3097, by Senator Smith, and H. R. 10272, by Representative Frelinghuysen (Republicans, N. J.), and H. R. 10236, by Representative Holt (R., Calif.). H. R. 10102 was discussed in THE JOURNAL, April 26, 1958, page 2188.

This bill would establish the type of information concerning employee welfare benefit plans that would be required to be made available to participants and beneficiaries of such plans. An "employee welfare benefit plan" is defined as "any plan, fund or program . . . established by an employer or by an employee organization, or by both, for the purpose of providing its participants or their beneficiaries, through the purchase of insurance or otherwise, medical, surgical or hospital care or benefits, in the event of sickness, accident, disability, death or unemployment." The bill provides that a description of the plan and annual financial reports containing specified information shall be made available for examination by any participant or beneficiary in the principal office of the plan. A participant or beneficiary has the right to request a copy of the plan and latest annual report, and the administrator of the plan would be required to mail it to him within 30 days. The administrator of the plan would also be required to file with the Secretary of Labor two copies of the description of the plan and annual reports to be made available for examination in the public document room of the Department of Labor. Violation of the disclosure sections would make an individual liable to a fine of up to $1,000 or imprisonment of up to six months. If an administrator refuses or fails to fill the request of a participant for information contained in the plan or annual reports, the administrator could, at the court's decision, become liable to the participant or beneficiary in the amount of $50 a day from the date of refusal or failure.

Unlike S. 2888, which has passed the Senate, this bill does not require the registration of welfare benefit plans with the Secretary of Labor. Nor does it provide him with authority to investigate or enjoin any activities or practices of officials of the welfare benefit plans. It is noted that the House amended S. 2888 to conform to provisions of H. R. 13507.

Taxes

H. R. 12725, by Representative Simpson (D., Pa.), on a tax deferment for self-employed is similar to H. R. 10, the Jenkins-Keogh Bill, as it passed the House. Unlike H. R. 10, which would allow a deduction from the annual income of 10% or $2,500, whichever is less, this bill allows 10% or $3,000, whichever is less.

H. R. 12909, by Representative Fogarty (D., R. I.), and H. R. 13125, by Representative Libonati (D., Ill.), pertains to tax deferment for self-employed and is identical to H. R. 9 and 10 (Jenkins-Keogh bills).

H. R. 13583, by Representative Fascell (D., Fla.), is identical to H. R. 10, the Jenkins-Keogh bill, as it passed the House. The bill did not pass the Senate; however, chances for its passage next session look extremely favorable. This bill would permit a self-employed individual to deduct from adjusted gross income an amount equal to 10% of net earnings from self-employment or $2,500 annually, whichever is the lesser. No deductions would be allowed for any taxable year after the individual attains age 70. The maximum in an individual's lifetime would be 20 times the maximum annual deduction allowable, but in no case could it be more than $50,000. For individuals aged 50 or older on Jan. 1, 1959, the annual limit would be increased by one-tenth for each full year in excess of 50, as determined on Jan. 1, 1959. Thus, for an individual aged 60 on that date, the annual limit on his deduction would be 20% of self-employment income up to a maximum of $5,000.

A special limitation is imposed on individuals who have previously received benefits under an employer's pension, profit-sharing, or stock bonus plan. Included in such plans would be a pension or retirement plan (including military) established by the United States or any political subdivision thereof. Such an individual would have his lifetime limit (20 times his allowable annual deduction) reduced by the number of years he was covered by such retirement plan. Thus, an individual covered under a civil service retirement program for 15 years would be allowed a maximum lifetime deduction of five times his annual allowable deduction. No individual would be allowed a deduction in any year in which he receives any benefit under any of the above pension plans.

A self-employed individual is defined as one who is subject to the tax on self-employment income under the social security law—doctors and clergymen. In addition, self-employed individuals who also receive wages up to $4,200, which are subject to the employee tax under the social security program, would be eligible.

Payments may be made to purchase a restricted retirement policy from a domestic insurance company or to build up a restricted retirement fund at a bank which must be the trustee (custodian accounts provided in original H. R. 10 have been eliminated). No life insurance benefits could be provided under a restricted retirement policy after age 70 or older. Payments under such a policy must begin by 70½ years. Annuities may be only life annuities on the insured or joint and survivor annuities on the insured and his spouse. Payments from a restricted retirement fund also must begin by 70½ years of age and be completed by age 80. Certain restrictions are placed on investments on restricted retirement funds.

Benefits received after age 65 are to be considered as part of gross income and subject to the regular tax unless a lump sum payment is received. In such a case the tax would be computed by finding the increase in tax resulting from including one-fifth of the total payment in gross income and multiplying the tax increase by five. If an individual, before achieving age 65, "takes down" more than $2,500, the tax would be 110% of the aggregate increase in tax, had the amount been received equally in the taxable year and the four preceding years. If the amount is less than $2,500, the tax would be 110% of the tax attributable to the "take down."

Where an individual dies, the amount of death benefits equal to the cash surrender value of the restricted retirement policy at the time of death would be treated as income to the beneficiaries.

The life insurance benefits would not be considered part of their gross income. Amounts paid to decedent's beneficiaries under the restricted retirement trust fund would be considered taxable as gross income.

H. R. 13743, by Representative Holt (R., Calif.), would amend the Internal Revenue Code to provide, among other things, a tax deduction of all medical expenses incurred by a taxpayer for himself, his spouse, or a dependent. It also would allow an annual deduction up to $900 of all amounts paid a college as tuition or fees for the education of the taxpayer, his spouse, or a dependent.

Miscellaneous

H. R. 12612, by Representative Kilday (D., Texas), pertains to federal workers payroll deduction for health insurance. It is virtually identical to H. R. 10694, by Representative McFall (D., Calif.), discussed in The Journal, June 7, 1958, page 747.

S. 4055, by Senators Sparkman and Hill (Democrats, Ala.), would establish a program of Civil Defense survival depots to provide subsistence for civilian population evacuated from potential target areas in the event of attack. The purpose of this bill is to establish survival depots to provide housing, clothing, and feeding of individuals who would evacuate heavily populated areas in the event of war. The bill would establish an Emergency Survival Board composed of the director of the Office of Defense and Civilian Mobilization, who would be chairman, the Secretary of Defense, and the Secretary of Agriculture. The board would be responsible for (1) determining which cities would be likely targets; (2) the danger zone from which persons would be evacuated; (3) the number of such evacuees; and (4) the areas to which evacuees would be taken. In such evacuation areas the board would establish survival depots consisting of warehouses and other facilities, including sanitation and emergency water supplies, as the board would deem necessary. The depots would contain tents, cots, clothing, medical supplies, and foods from surplus government stocks. Stocks of food and fiber to be used in building up supplies would be obtained from the Commodity Credit Corporation or from domestic sources. The board would contract with individuals and organizations in the evacuation area for the preparation and processing of the food and fiber. The supplies would be rotated from time to time as the board deems advisable. In carrying out the purposes of the bill, the board would be expected to cooperate with the American Red Cross, state and local governments, and other groups which would be of assistance in establishing the program.

H. R. 12581, by Representative Edmondson (D., Okla.), H. R 13089, by Representative Dellay (D., N. J.), and H. R. 13420, by Representative Blatnik (D., Minn.), are similar to S. 3576, by Senator Humphrey, and H. R. 11714, by Representative Blatnik (Democrats, Minn.), and H. R. 12166, by Representative Lankford (D., Md.), and would amend the Water Pollution Control Act to increase one of the limitations on grants for construction from $250,000 to $500,000 and for other purposes.

H. R. 13420, which was favorably reported by the House Committee, is identical to H. R. 11714 (*J. A. M. A.* 167:1520 [July 19]) except that it requires the surgeon general to take action to insure that contractors pay wages equal to those prevailing in the local community as provided in the Davis-Bacon Act.

S. 4160, by Senator Bennett (R., Utah), would establish a program of loans for the purpose of encouraging and assisting individuals to obtain a college education.

The bill would authorize the establishment of a 75 million dollar revolving fund from which loans of up to $2,000 per year could be made to students pursuing a course toward a baccalaureate degree or such postgraduate degrees in the individual's chosen academic area, except for such special cases as the Commissioner of Education may designate.

To qualify for a loan, the applicant would have to be certified as acceptable by the college. The loan would be made without security on the signature of the borrower. (If the applicant is a minor, the note would have to be endorsed by his parent or guardian.) The loan, which would bear interest equal to the average annual rate on United States obligations, would be due and payable five years after the borrower ceases a full-time course of study. Twenty-five per cent of the loan would be cancelled for individuals majoring in the physical sciences if they graduate in the upper 25% of their class.

S. J. Res. 199, by Senator Hill (D., Ala.), is similar to H. J. Res. 698, by Representative Fogarty (D., R. I.), and would establish the National Advisory Council for International Medical Research and to establish a National Institute for International Medical Research. The purpose of this joint resolution is to encourage and support international studies, experiments, and research into the causes diagnosis, treatment, and control of physical and mental diseases. It would also authorize research in rehabilitation of the physically handicapped, provide for international exchange of knowledge and information resulting from research, and provide for the exchange, between the United States and other countries, of research workers for training and for carrying out research in physical diseases. The Secretary of HEW would carry out the purposes of the joint resolution and would be authorized to utilize the Public Health Service and the Office of Vocational Rehabilitation and other agences.

The resolution would establish a National Institute of International Medical Research to carry out such functions, including grants for research and research training in facilities outside the United States, as may be assigned by the surgeon general. The resolution also would establish a National Advisory Council on International Medical Research. This council, whose chairman would be the surgeon general, would be composed of 18 members, 16 of whom, appointed by the Secretary, would be from the fields of medical research, teaching, medical, or biological science, rehabilitation, education, or public and international affairs. Eight of the 16 members would be leading experts in the field of international medical research. One of the members would be a representative of the Secretary of State and the Director of the Office of Vocational Rehabilitation would be an ex officio member. The council would meet at least three times a year. No international research or training project could be approved, except after review and recommendation by the Council. The Secretary, through the surgeon general, would be required to make provision for coordination of the work of the council and the National Advisory Health Council and other advisory councils concerned with research and rehabilitation. The resolution specifically forbids the support of public health programs of an operational nature and limits activities to research matter. The bill authorizes 50 million dollars annually to carry out its purposes.

Veterans Affairs

H. R. 12636, by Representative Moulder (D., Mo.), is similar to H. R. 12873 and H. R. 12874, both by Representative Moulder, and would provide that the death, regardless of cause, of any veteran of World War I would be conclusively presumed to be service-connected if (1) the veteran has been rated for 12 or more years as totally disabled from a service-connected disability, (2) if he has been rated as totally disabled for a service-connected disability for a 10-year period following his 50th birthday, or (3) if the veteran has been rated as totally disabled for a service-connected disability after he has reached his 62nd birthday. Presumably, the purpose of this bill is to provide increased benefits for the widows and dependents of qualifying veterans.

H. R. 13720, by Representative Beckworth (D., Texas), would amend the Veterans' Benefits Act of 1957 to authorize the granting of hospital care to any veteran in need of such care. This bill would make any veteran eligible for hospital care in VA facilities who submitted competent evidence of his need for hospital care.

Social Security

H. R. 12701, by Representative Flood (D., Pa.), is identical to H. R. 7086, by Representative Blatnik (D., Minn.). It would provide for a pay-as-you-go national program of social security to be supported by "an equitable gross income tax." In addition to providing retirement payments to all persons in the United States at the age of 60, it would provide similar benefits for disabled persons, certain children, and for certain cases where the female heads the family.

H. R. 12911, by Representative Moore (R., W. Va.), would increase social security benefits and tax rate. This bill is identical with H. R. 12493, by Representative Boggs (D., La.), reported in The Journal, Aug. 23, 1958, page 2085.

H. R. 12936, by Representative Lesinski (D., Mich.), would amend the Social Security Act to provide, among other things, increased monthly benefits. This bill would amend the Social Security Act by lowering the retirement age for both men and women to age 60 and increase present monthly money benefits by 15%. To finance these increases, the tax rate on the present wage base of $4,200 would be increased. On Jan. 1, 1959, the tax would be increased for the self-employed from the present $141.75 to $236.25; in 1975 the tax would reach $378.00. For the employed, the present tax of $94.50 would be increased to $157.50 on Jan. 1, 1959, and by 1975 the employer and employee would each pay $252.00 under the proposed changes.

H. R. 12977, by Representative Bennett (R., Mich.), would amend the Social Security Act to provide, among other things, medical benefits for certain social security beneficiaries as follows:

Hospital, Nurse-Home, and Surgical Benefits.—A program of hospital, nursing home, and surgical benefits would be initiated for an individual (and spouse) who is eligible for retirement benefits under OASI. The bill would provide up to 60 days of hospitalization in any 12-month period in semi-private accommodations and nursing home care up to a combined total of 120 days in the same period. It would also cover the cost of surgical care (not elective surgery) with freedom by the beneficiary to choose a surgeon of his choice, provided the surgeon is certified by the American Board of Surgery or is a member of the American College of Surgeons (except in cases of emergency.) Unlike the Forand Bill, H. R. 9467, this bill does not provide for oral surgery performed by a dentist nor does it provide for minor surgery in a doctor's office, except in cases of emergency.

Hospital care could be received only in those hospitals which has entered into an agreement with the government. Eligible nursing homes would be those where skilled nursing care could be obtained and which are operated in connection with a hospital or in which nursing care and medical services are prescribed by, or performed under the general direction of persons licensed to practice medicine or surgery in the state. Treatment in a tuberculosis or a mental hospital would be specifically precluded. The hospital would not receive payment from the OASI trust fund if payment were due under a workmen's compensation law or under a plan of any state or the United States. In the event that the OASI trust fund paid for such hospital or other medical services and it was subsequently determined that a workmen's compensation or other state or federal plan is liable for such expenses, then the United States would be subrogated to all rights of the beneficiary or the provider of services to whom payment had already been made. Physicians would be paid in amounts as specified in agreement made with the Secretary of HEW or as prescribed in regulations promulgated by him.

The Secretary of HEW could utilize the services of private nonprofit organizations which (*a*) represent qualified providers of hospital, nursing home, or surgical services; or (*b*) operate voluntary health insurance plans. These nonprofit groups could be utilized as fiscal agents but only to the extent that the Secretary of HEW "can make satisfactory arrangements with them and to the extent he determines such utilization would contribute to the effective and economic administration.

To qualify for the above medical benefits a person would have to be entitled to OASI retirement benefits and have an income (including the income of his spouse and monthly insurance benefits received under the Social Security Law) of less than $2,400 in the preceding 12-month period. Such an individual's spouse would also be entitled to dependents' benefits under the Social Security Law, including widows, and would be entitled to the medical benefits. All regulations to implement the provisions of this bill would be prescribed by the Secretary of HEW. The Forand bill provides for a nine-man National Advisory Health Council to consult with the Secretary and presumably aid him in the drafting of regulations. The bill would prohibit the Secretary from having supervision or control over the practice of medicine or administration and operation of hospitals and nursing homes.

Redefine Disability.—Under existing law disability is defined as inability to engage in any substantial gainful activity by reason of a medically determinable physical or mental impairment which can be expected to result in death or to be of a long-continued and indefinite duration. This bill would change the definition to read: "inability of an individual by reason of any medically determinable physical or mental impairment which can be expected to be permanent or of long-continued and indefinite duration, to engage in a substantial gainful activity which is the same as or similar to the occupation or employment last performed by him on a regular basis before the onset of such impairment.

Liberalize Coverage Requirements for Disability Benefits. The bill also would change the coverage requirements for the disability freeze and for disability cash payments. Among other coverage requirements under existing law, a disabled individual must have been in covered employment for 20 out of the 40 quarters preceding the onset of disability. This bill would reduce the requirement to 15 quarters of coverage during the 30-quarter period prior to the onset of disability.

Retirement Age.—Under existing law, the retirement age is 65, although women may receive reduced benefits at age 62. This bill would reduce the retirement age for women to 60 and for men to 62.

Increased Benefits.—The maximum primary benefit would be raised from the present $108.50 per month to $150.60; the minimum primary benefit would be increased from the present $30 to $50; while the maximum family benefit would be increased from $200 to $305.

Wage Base and Tax Rate Increase.—To pay for these new and increased benefits, the wage base upon which social security taxes are paid would be increased from the present $4,200 to $6,000. The tax rate for the self-employed would be increased in 1959 from the present 3.375% to 6.375%; the employee and employer tax rate would be increased from the present 2.25% each to 4.25%. For the period 1961 to 1964, these taxes would be increased from the presently scheduled 4.125% to 7.125% for the self-employed and from 2.75% to 4.75% for the employer and employee. By 1975 these taxes would be increased from the presently scheduled 6.375% to 9.375% for self-employed and from 4.25% to 6.25% for the employer and employee.

On Jan. 1, 1959, the tax would be increased for the self-employed from the present $141.75 to $382.50; in 1975 the tax would reach $562.50. For the employed, the present tax of $94.50 would be increased to $255.00, and by 1975 the employer and employee would each pay $375.00.

H. R. 12979, by Representative Green (D., Ore.), would amend the Public Assistance provisions of the Social Security Act to provide assistance for temporarily disabled individuals by changing that section of the Social Security Act which provides public assistance for the permanently and totally disabled by striking the term "permanently and totally" wherever it occurs. It would also remove any individual from eligibility for benefits "who has not been disabled for a period of at least 30 days." The effect of this bill would be to establish a program of public assistance for the temporarily disabled.

H. R. 12986, by Representative Ullman (D., Ore.), would amend the Social Security Act to provide, among other things, an increase in the wage base and tax rate and to increase benefits payable thereunder.

This bill would (1) provide for increased benefits under social security; (2) reduce the retirement age for women to age 62; (3) increase widows' insurance benefits from 75% to 85% of the primary benefits; and (4) provide insurance for the dependents of disability insurance beneficiaries. To meet the cost of these liberalizations, the wage base upon which social security taxes are paid would be increased from the present $4,200 to $6,000 and the tax rate would be increased for the self-employed beginning in 1959 from the present 3.375% to 4.125%, with periodic increases so that by 1975 the self-employed would be paying 7.125% on the $6,000 wage base. The taxes for the employee and employer would be increased beginning in 1959 from the present 2.25% to 2.75%, with periodic increases so that by 1975 each would be paying 4.75% on the $6,000 wage base.

On Jan. 1, the tax would be increased for the self-employed from the present $141.75 to $247.50; in 1975 the tax would reach $427.50. For the employed, the present tax of $94.50 would be increased to $157.50, and by 1975 the employer and employee would each pay $285.00 under the proposed changes.

S. 4121, by Senator Case (R., N. J.), and others would amend the Social Security Act to increase the benefits payable under the old-age, survivors, and disability insurance program. This bill would increase the monthly social security benefits by increasing the social security wage base and tax rate and by accelerating the periodic increases provided in existing law. A table for determining benefits would be substituted for the formula contained in the law. Minimum benefits would be increased from $30 to $33 monthly; maximum individual benefits would be increased from the present $108.50 to $119.40, and the maximum family benefit would be increased from the present $200 to $260.80. To meet the cost of these increased benefits, the wage base would be increased from the present $4,200 to $4,800. The tax rate for self-employed individuals beginning on Jan. 1, 1959, would be raised from the present 3.375% to 3.75% (from present $141.75 to $180). Beginning in 1960 and every four years thereafter, these taxes would be increased periodically so that beginning in 1972 the self-employed would be paying 6.75%. Existing law provides that in 1975 the self-employed would be paying 6.375%. Thus, in 1972 the self-employed individual would pay a tax of $324. Both the employee and the employer would have their tax rate increased in 1959 from the present 2.25% to 2.5% (from $94.50 to $120). Beginning in 1960 and every four years thereafter, the rate would be increased by 0.5% until 1972, when the rate for the employee and employer would be 4.5% for each. Thus, beginning in 1972, the employee and employer each would be paying $216.

H. R. 13205, by Representative Byrd (D., W. Va.), would liberalize disability benefits requirements. This bill is identical to S. 1812, by Senator Revercomb (R., W. Va.), which would amend the coverage requirements for applicants for disability benefits under the Social Security Act. Under the present law before an applicant can receive disability payments, he must be fully insured (40 quarters of coverage or one-half the quarters since 1950, with a minimum of six quarters) and have been covered 1½ years out of 3 years and 5 out of the 10 years immediately prior to the onset of his disability. This bill would permit disability payments to be made if the applicant had "at lease one quarter of coverage."

H. R. 13206, by Representative Byrd which is identical to S. 1811, by Senator Revercomb, and would redefine "disability" under Social Security as used in the disability benefits provisions of the Social Security Act. Under the present definition, an applicant for disability benefits is eligible only if he is found unable to engage in any substantial gainful activity. Under this proposal, if, as a practical matter, the applicant could not obtain employment, he would be eligible for disability payments.

H. R. 13308, by Representative Moulder (D., Mo.), would amend Title I of the Social Security Act to increase the amount of federal funds payable thereunder to states which have approved plans for old-age assistance. This bill would increase the maximum toward which the federal government may contribute for aid to the needy aged from the present $60 to $75 and would change the formula so that the federal contribution could be larger. Under the present law, the maximum amount the federal government can contribute is $39 of the $60 limit; under this proposal the federal contribution could be a maximum of $49.17 of the $75 limit. In addition to the above funds, the federal government would pay one-half of the states' administrative costs in carrying out the old-age assistance program. The most notable feature of the bill is that it would eliminate vendor medical payments for this public assistance program. Presumably, the recipients would be expected to pay for their medical care from their benefits. The bill does not amend the remaining three programs of public assistance—aid to dependent children, the blind and the permanently and totally disabled.

H. R. 13549, by Representative Mills (D., Ark), and H. R. 13550, by Representative Reed (R., N. Y.), would liberalize the social security law by increasing benefits and to provide actuarial soundness of the trust funds by increases in the wage base and tax rate and the acceleration of periodic tax increases.

MEDICINE AND THE LAW

TORT LIABILITY OF CHARITABLE HOSPITALS TO PATIENTS

In 1876, the Supreme Court of Massachusetts, in *McDonald v. Massachusetts General Hospital,* 120 Mass. 432, first announced the rule in the United States that a charitable hospital is not liable for injuries caused by the negligence of its agents and employees. The decision was based upon an English case, *Holliday v. St. Leonard's,* 11 C.B., N.S. 192 (1860), which in turn was based upon the dictum in an earlier English case, *Duncan v. Findlater,* 7 Eng. Reprint 934 (1839). However, the dictum in the *Duncan* case had been overruled in 1866 in *Mersey Docks Trustees v. Gibbs,* 11 Eng. Reprint 1500, and the *Holliday* case had been reversed in 1871 *in Foreman v. Mayor of Canterbury,* L.R. 6 Q.B. 214. Although the *Holliday* case had been reversed and the dictum of the earlier case overruled even before the date of the Massachusetts decision, charitable hospitals have nevertheless been held to be immune by many courts throughout the United States as a result of this decision.

A Rhode Island court in 1879 chose to reject the doctrine of immunity, and in *Glavin v. Rhode Island Hospital,* 12 R.I. 411, a charitable hospital was held liable for injuries caused by the negligence of an intern. But shortly thereafter, the Rhode Island legislature enacted a statute granting immunity and thereby repudiating the *Glavin* decision.

Since the *McDonald* decision in 1876, the general rule in the United States has been that of immunity or qualified immunity. However, in recent years the trend has been toward the liability of charitable hospitals for the torts of their employees and agents. In the following states the courts have held charitable hospitals to be fully liable for the torts of their employees and agents the very first time the issue of liability arose: Delaware (1951), Minnesota (1920), New Hampshire (1939), North Dakota (1946), Rhode Island (1879) (overruled by statute), and Vermont (1950).

In the following states, full liability was adopted as the rule even though the courts of these states had previously followed variations of the rule of immunity or qualified immunity: Arizona (1951), California (1951), Iowa (1950), Kansas (1954), New Jersey (1958), New York (1957), and Ohio (1956).

Despite the trend of the state courts in reversing their previous rules of immunity, the courts of Pennsylvania (1958) and Connecticut (1957) have noted the action of other courts but have refused to disturb their rules of immunity on the ground that such action is the prerogative of the legislature.

In 1952, the Alaska court considered the question of liability for the first time and held a charitable hospital liable to a patient who payed only part of the cost of his hospitalization. In 1954, a federal court declared that the rule of charitable immunity does not apply in Alaska. Mississippi (1951), Washington (1953), and Idaho (1956) have held charitable hospitals liable to paying patients, the latter two states reversing previous holdings. Although these cases were limited to facts involving paying patients, the court's decision in each instance left the impression that a similar decision would be reached with regard to nonpaying patients.

The names and citations of the cases referred to above are shown in the summary which follows this discussion.

The landmark case which appears to have given the current trend toward liability its great impetus is a District of Columbia, Court of Appeals decision, *President and Directors of Georgetown College v. Hughes,* 130 Fed. (2d) 810, 76 App. D. C. 123 (1942). Three of the judges who participated in the decision (Rutledge, Miller, and Edgerton, J. J.) held that charitable institutions enjoy no immunity from tort liability. The three other judges (Groner, Ch.J., Stephens, and Vinson, J. J.) expressed no opinion on the question of complete liability and concurred only on the issue raised by the facts of the case that charitable corporations are responsible for the negligence of their servants causing injury to strangers. These words in the opinion written by Associate Justice Rutledge seem to summarize the trend and philosophy of current judicial thinking in tort law as it applies to charitable institutions:

> The rule of immunity is out of step with the general trend of legislative and judicial policy in distributing losses incurred by individuals through the operation of an enterprise among all who benefit by it rather than in leaving them wholly to be borne by those who sustain them. The rule of immunity itself has given way gradually but steadily through widening, though not too well or consistently reasoned, modifications. It is disintegrating. Each modification has the justification that it is a step in result, if not in reason, from the original error toward eventual correction. . . .
>
> . . . It does not recompense injured persons that the loss inflicted is by charitable institutions. . . . We do not believe the survival of charities will turn on whether they must answer for their wrongs to persons they are formed to help. There may be some added expense of operations. It may be no more than the cost of litigating these claims over and over, for the issue will not be down. Insurance must be car-

ried to guard against liability to strangers. Adding beneficiaries cannot greatly increase the risk or the premium. This slight additional expense cannot have the consequences so frequently feared in judicial circles, but so little realized in experience. To offset the expense will be the gains of eliminating another area of what has been called "protected negligence" and the anomaly that the institutional doer of good asks exemption from responsibility for its wrong, though all others must pay.

In the absence of legislative action to the contrary, it appears that the rule of charitable immunity is likely to disappear in the not too distant future.

Tort Liability of Charitable Hospitals to Patients in The United States

Alabama	Liable to paying patient. Tucker v. Mobile Infirmary Assn., 68 So. 4, 191 Ala. 572 (1915). No reported court decisions involving charity patients although the Tucker case may be interpreted to indicate full liability.
Alaska	Full liability. Moats v. Sisters of Charity, 13 Alaska 546 (1952); Tuengel v. Sitka, 118 F. Supp. 399 (1954).
Arizona	Full liability. Ray v. Tucson Medical Center, 230 P. (2d) 220, 72 Ariz. 22 (1951).
Arkansas	Immune from liability to nonpaying patients except for negligence in the selection and retention of employees. Arkansas Midland R. Co. v. Pearson, 135 S. W. 917, 98 Ark. 399 (1911). No reported court cases involving paying patients.
California	Full liability. Malloy v. Fong, 232 P. (2d) 241, 37 Cal. (2d) 356 (1951); Section 1714 California Civil Code.
Colorado	Execution under a judgment rendered against a charity in a tort action cannot be levied on property which is part of the charitable trust. St. Mary's Academy v. Solomon, 238 P. 22, 77 Colo. 463 (1925). Liability within limits of insurance coverage. O'Connor v. Boulder Colorado Sanitarium Assn., 96 P. (2d) 835, 105 Colo. 259 (1939).
Connecticut	Immune from liability except for negligence in the selection and retention of employees. Hearns v. Waterbury Hospital, 33 A. 595, 66 Conn. 98 (1895); McDermott v. St. Mary's Hospital, 133 A. (2d) 608 (1957).
Delaware	Full liability. Durney v. St. Francis Hospital, 83 A. (2d) 753 (1951).
District of Columbia	Question of liability not authoritatively decided. Dicta expressing full liability in Court of Appeals decision, President and Directors of Georgetown College v. Hughes, 130 Fed. (2d) 810, 76 App. D.C. 123 (1942). A trial court held that hospital is immune from liability for injuries sustained by a patient through the negligence of its nurses where there is no claim that they were negligently selected by the hospital or that hospital itself was negligent. White v. Providence Hospital, 80 F. Supp. 76 (1943).
Florida	Liable to paying patients. Nicholson v. Good Samaritan Hospital, 199 So. 344, 145 Fla. 360 (1941). No reported cases involving charity patients although the doctrine of full liability is dicta in Wilson v. Lee Memorial Hospital, 65 So. (2d) 40 (1953).
Georgia	Liable for negligence in selecting and retaining employees; execution on a judgment recovered for such negligence is not limited to nontrust assets. Liable to paying patient for negligence of employees even though they have been selected with due care, but judgment can be executed only from income derived from paying patients or insurance. Morton v. Savannah Hospital, 6 S.E. 887, 148 Ga. 438 (1918).
Hawaii	No reported cases.
Idaho	Liable to paying but not to nonpaying patients. Wheat v. Idaho Falls Latter Day Saints Hospital, 297 P. (2d) 1041 (1956).
Illinois	Liable within limits of liability insurance and other nontrust assets. Moore v. Moyle, 92 N.E. (2d) 81, 405 Ill. 555 (1950).
Indiana	Immune from liability to charity and paying patients unless hospital failed to exercise reasonable care in selecting and retaining employees who committed tort, in which case there is no immunity. St. Vincent's Hospital v. Stine, 144 N.E. 537, 195 Ind. 350 (1924).
Iowa	Full liability. Haynes v. Presbyterian Hospital, 45 N.W. (2d) 51, 241 Iowa 1269 (1950).
Kansas	Full liability. Noel v. Menninger Foundation, 267 P. (2d) 934 (1954).
Kentucky	Complete immunity from liability. Emery v. Jewish Hospital Ass'n., 236 S.W. 577, 193 Ky. 400 (1921).
Louisiana	Immune from liability. Jordan v. Touro Infirmary, 123 So. 726 (1922). But immunity of assured unavailable as defense by insurer. Stamos v. Standard Accident Ins. Co., 119 F. Supp. 245 (1954).
Maine	Immune from liability. Jensen v. Maine Eye & Ear Infirmary, 78 A. 898, 107 Me. 408 (1910).
Maryland	Immune from liability. Howard v. South Baltimore General Hospital, 62 A. (2d) 574 (1948). Exception: liability within limits of insurance coverage (provided by statute); Gorman v. St. Paul Fire & Marine Ins. Co., 121 A. (2d) 812 (1956).
Massachusetts	Immune from liability. McDonald v. Massachusetts General Hospital, 21 Am. Rep. 529, 120 Mass. 432 (1876).
Michigan	Immune from liability. Pepke v. Grace Hospital, 90 N.W. 278, 130 Mich. 493 (1902).
Minnesota	Full liability. Mulliner v. Evangelischer Diakonniessenverein, 175 N.W. 699, 144 Minn. 392 (1920).
Mississippi	Liable to paying patients. Mississippi Baptist Hospital v. Holmes, 55 So. (2d) 142 (1951). Liable for negligence in the selection and retention of employees. Mississippi Baptist Hospital v. Moore, 126 So. 465, 156 Miss. 676 (1930).
Missouri	Immune from liability. Dille v. St. Luke's Hospital, 196 S.W. (2d) 615, 355 Mo. 436 (1946).
Montana	No reported cases.
Nebraska	Immune from liability. Cheatham v. Bishop Clarkson Memorial Hospital, 70 N.W. (2d) 96, 160 Neb. 297 (1955); Muller v. Nebraska Methodist Hospital, 70 N.W. (2d) 86, 160 Neb. 279 (1955).
Nevada	Immune from liability to nonpaying patients. Springer v. Federated Church of Reno, 283 P. (2d) 1071 (1955). No reported cases involving paying patients.
New Hampshire	Full liability. Welch v. Frisbie Memorial Hospital, 9 A. (2d) 761, 90 N.H. 337 (1939).
New Jersey	Full liability. Collopy v. Newark Eye & Ear Infirmary, 141 A. (2d) 276 (1958).
New Mexico	No reported court decisions.
New York	Full liability. Bing v. Thunig, 143 N.E. (2d) 3, 163 N.Y.S. (2d) 3 (1957).
North Carolina	Immune from liability. Williams v. Union County Hospital Assn., 75 S.E. (2d) 308, 237 N.C. 395 (1953). Exception: liable f[illegible] and retention of employees. [illegible] spital Inc., 75 S.E. (2d) 303, 23 [illegible]
North Dakota	Full liability. Rickbell v. Grafton Deaconess Hospital, 23 N.W. (2d) 247, 74 N.D. 525 (1946).
Ohio	Full liability. Avellone v. St. John's Hospital, 135 N.E. (2d) 410 (1956).
Oklahoma	Liable to paying patients. Sisters of the Sorrowful Mother v. Zeidler, 82 P. (2d) 996, 183 Okla. 454 (1938). No reported cases involving charity patients.
Oregon	Immune from liability. Gregory v. Salem General Hospital, 153 P. (2d) 837, 175 Ore. 464 (1944).
Pennsylvania	Immune from liability. Gable v. Sisters of St. Francis, 75 A. 1087, 227 Pa. 254 (1910); Knecht v. St. Mary's Hospital, 140 A. (2d) 30 (1958).
Rhode Island	Immune from liability by statute. General Laws, Section 7-1-22 (1956).
South Carolina	Immune from liability. Lindler v. Columbia Hospital, 81 S.E. 512, 98 S.C. 25 (1914).
South Dakota	No reported cases.
Tennessee	Full liability but damages not recoverable out of trust property. Vanderbilt University v. Henderson, 127 S.W. (2d) 284, 23 Tenn. App. 135 (1938).
Texas	Immune from liability. Exception: liable for negligence in selection or retention of employees. Jones v. Baylor Hospital, 284 S.W. (2d) 929 (1955).
Utah	Liable to paying patients and probably also to nonpaying patients. Sessions v. Thomas P. Dee Memorial Hospital, 78 P. (2d) 645, 94 Utah 460 (1938).
Vermont	Full liability. Foster v. Roman Catholic Diocese of Vermont, 70 A. (2d) 230, 116 Vt. 124 (1950).
Virginia	Immune from liability. Weston v. Hospital of St. Vincent, 107 S.E. 785, 131 Va. 587 (1921). Exception: liable for negligence in selection and retention of employees. Norfolk Protestant Hospital v. Plunkett, 173 S.E. 363, 162 Va 151 (1934).
Washington	Liable to paying but not to nonpaying patients. Pierce v. Yakima Valley Memorial Hospital, 260 P. (2d) 765 (1953). Liable for negligence in selection or retention of employees. Canney v. Sisters of Charity, 130 P. (2d) 899, (1942).
West Virginia	Immune from liability. Meade v. St. Francis Hospital, 74 S.E. (2d) 405, 137 W. Va. 834 (1953). Exception: liable for negligence in selection or retention of employees. Roberts v. Ohio Valley General Hospital, 127 S.E. 318, 98 W. Va. 476 (1925).
Wisconsin	Immune from liability. Grabinski v. St. Francis Hospital, 63 N.W. (2d) 693, 266 Wis. 339 (1954). Liable for negligence in selection or retention of employees. Schumacher v. Evangelical Deaconess Society, 260 N.W. 476, 218 Wis. 169 (1935).
Wyoming	Immune from liability to nonpaying patients. Bishop Randall Hospital v. Hartley, 160 P. 385, 24 Wyo. 408 (1916). No reported cases involving paying patients.

MEDICAL NEWS

ARIZONA

Regional Meeting of Physicians.—The Arizona regional meeting of the American College of Physicians will be held Oct. 18 at St. Luke's Hospital, Phoenix, under the general chairmanship of Dr. William R. Hewitt. Invited speakers include Drs. Earl J. Baker, Phoenix, and Preston J. Taylor, Tucson, who will give "New Developments in Hypothermia" and "Malabsorption Syndrome," respectively. Speaker at the banquet in the Safari Hotel, Scottsdale, will be Dr. Fuller B. Bailey, professor of medicine, University of Utah College of Medicine, Salt Lake City, and regent of the college. There is no registration fee. For information write Dr. Leslie B. Smith, 1130 E. McDowell Road, Phoenix, Ariz.

ARKANSAS

Appoint Professor of Anatomy.—Horace N. Marvin, Ph.D., has been promoted professor and head of the department of anatomy at the University of Arkansas Medical Center, Little Rock. Dr. Marvin, who joined the School of Medicine faculty in 1942 and has been an associate professor since 1949, succeeds Dr. William C. Langston, who has reached emeritus rank after serving on the faculty for 28 years.

CALIFORNIA

Punch in Galvanized Container Poisonous.—According to the Morbidity and Mortality Weekly Report of the Public Health Service for Sept. 5, the California Department of Public Health has reported an outbreak of food poisoning following the consumption of a punch drink served in a coffee shop. Fourteen of 25 persons who drank the punch became ill with cramps and diarrhea from 15 to 45 minutes after drinking the suspect beverage. The punch, consisting of a commercial mix, fresh and bottled lemon juice, sugar, and water, was prepared in a galvanized iron container and then stored in a refrigerator. The lining of the cans had been extensively corroded by the punch. Chemical analysis of a sample of the punch showed zinc present in the proportion of 184 parts per million. No other toxic heavy metals were found.

Dr. Topping Named University President.—Dr. Norman H. Topping took office Sept. 2 as president of the University of Southern California, his alma mater. Dr. Topping returned to Southern California from the University of Pennsylvania, where he had been vice-president for medical affairs six years. He formerly was an assistant surgeon general of the U. S. Public Health Service and associate director of the National Institutes of Health at Bethesda, Md. During World War II he was a member of the U. S. Typhus Commission and won its medal. He also has received the Bailey K. Ashford award of the American Society of Tropical Medicine and the award of the Washington Academy of Science. Dr. Topping was president of the American Society of Tropical Medicine in 1949-50, and since 1956 has been chairman of the Committee on Virus Research and Epidemiology of The National Foundation.

FLORIDA

University Grants.—Melvin Fried, Ph.D., assistant professor of biochemistry at the University of Florida College of Medicine, Gainesville, has received a $32,660 grant from the National Institutes of Health to finance a three-year study devoted to the characterization of protein moieties of lipoproteins.——The U. S. Public Health Service has announced the awarding of a $24,000 grant to Dr. William W. Stead, associate professor of medicine at the University of Florida College of Medicine, Gainesville, to finance a two-year study for the development of an improved test of pulmonary ventilator function.

GEORGIA

New Chair at Emory.—Dr. Ross L. McLean has been appointed to the newly created chair of tuberculosis and pulmonary diseases at the Emory University School of Medicine, Atlanta, established by the Atlanta Tuberculosis Association. Dr. McLean was formerly director of professional services at the Veterans Administration Hospital in Baltimore, and an assistant professor of medicine at Johns Hopkins University.

ILLINOIS

Eye and Ear Infirmary Centennial Dinner.—In connection with the centennial observation of the founding of the Illinois Eye and Ear Infirmary, Chicago, the Illinois Department of Public Welfare, in cooperation with the University of Illinois, will join with the alumni associations of otolaryngology and ophthalmology in a celebration dinner at the Palmer House Hotel, Chicago, Oct. 15. The infirmary is dedicated to service, education, and research providing free medical services for indigent

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

citizens of Illinois suffering from diseases of the eye, ear, nose, and throat. For information write Dr. Otto L. Bettag, Director, Department of Public Welfare, State of Illinois, Springfield.

Chicago

Passavant Dedicates New Pavilion.—The new East Pavilion of Passavant Memorial Hospital was dedicated Sept. 21. The nine-story, 4 million dollar addition provides a potential 90 beds, increasing the hospital's patient capacity to 353. The surgery suite in the new wing includes eight operating rooms and allied treatment and diagnostic units. Two operating rooms have colored closed-circuit television equipment. Next to the auditorium is a conference room for classes and small meetings. The radiology department is equipped with an automatic processing machine which processes a film in eight minutes. Passavant is affiliated with Northwestern University Medical School as a teaching hospital.

INDIANA

Annual State Meeting in Indianapolis.—The 109th annual convention of the Indiana State Medical Association will be held at Murat Temple, Indianapolis, Oct. 12-15. Round-table luncheons Oct. 13 are listed as follows: "Hayfever and Other Allergies," Dr. Donald J. White, Indianapolis, "Current Status of the Correct Management of Thyroid Disorders," Dr. Glenn W. Irwin Jr., Indianapolis, and "Evaluation of Patients for Cardiac Surgery," Dr. Harris B. Shumacker Jr., Indianapolis. "Chemical Tests for Intoxication" will be a program consisting of a talk by Dr. Herman A. Heise, Milwaukee, vice-chairman of the American Medical Association Committee on Medicolegal Problems, followed by a two-hour mock trial demonstration and a special scientific exhibit on "Problems in Forensic Sciences by the Forensic Sciences Study Commission of the Legislative Advisory Commission of Indiana." Dr. Ralph D. Rabinovitch, Northville, Mich., and Esther J. Swenson, Ph.D., Tuscaloosa, Ala., are participants in the annual Conference of Physicians and Schools. A symposium, "Chronic Inflammatory Diseases of the Lungs," will include the following participants: Drs. Ted F. Leigh, Atlanta, Ga.; Averill A. Liebow, New Haven, Conn.; and Thomas H. Burford, St. Louis. A golf tournament, the annual trap-skeet shoot, and a program of ladies' entertainment are arranged. For information write the Indiana State Medical Association, 1021 Hume Mansur Building, Indianapolis 4, Ind.

MICHIGAN

Exchange Program for Interns and Residents.—Eighteen hospitals in 14 communities throughout Lower Michigan are now affiliated with The University of Michigan Medical Center, Ann Arbor, in an exchange program for the advanced training of interns and resident physicians. Dr. John M. Sheldon, professor of internal medicine and director, University of Michigan department of postgraduate medicine, described the four-part program now in effect: (1)—A program which permits residents from the affiliated hospitals studying internal medicine, surgery, or obstetrics and gynecology to spend their three-year terms at the University of Michigan Medical Center. This includes a nine-month course in the basic sciences preparatory to the state board examinations. (2)—A program under which university staff members visit each affiliated hospital six or more times a year to examine and evaluate the training programs. In addition, a conference is held at the university once a year so the educational committees may meet with the university staff members to coordinate their program. (3)—Training in general practice which provides annually for about 10 internships of two years each. These interns spend alternating six-month periods at the University of Michigan and at the affiliated hospitals. (4)—A program for student experience in general practice which permits senior medical students to spend their vacation period working in affiliated hospitals. University of Michigan faculty members visit the hospitals participating in this program about 12 times each year.

MONTANA

State Medical Election.—At the annual meeting of the House of Delegates of the Montana Medical Association Sept. 13 the following officers were elected and installed: president, Dr. Herbert T. Caraway, Billings; president-elect, Dr. Leonard W. Brewer, Missoula; vice-president, Dr. Raymond F. Peterson, Butte; secretary-treasurer, Dr. Theodore R. Vye (reelected), 412 N. Broadway, Billings, Mont.; assistant secretary-treasurer, Dr. William E. Harris, Livingston (reelected); executive committe, Drs. John A. Layne, Great Falls (reelected), Edward S. Murphy, Missoula (to serve in addition to the above named officers); delegate to American Medical Association, Dr. Paul J. Gans, Lewistown; alternate delegate, Dr. Sidney C. Pratt, Miles City.

NEBRASKA

Clinical Meeting in Omaha.—The Omaha Mid-West Clinical Society will hold its 26th annual sessions at the Sheraton-Fontenelle Hotel, Omaha, Nov. 3-6. Three panel discussions are planned; "Staphylococcus Infections," "Common Fractures," and "Obstetric Shock," moderated by Drs. Henry J. Lehnhoff Jr., Richard D. Smith, and Maurice E. Grier, respectively. Dr. Donald J. Wilson, Omaha, president-elect of the society, will moderate a symposium on Nov. 6 on "This is What's New!" Guest speakers are as follows: Drs. Benjamin M. Gasul, Chicago; Thomas H. McGavack, Martinsburg, W. Va.; Earl D. Osborne, Buffalo, N. Y.; Victor Goodhill and Myron Prinzmetal, Los Angeles; Louis T. Byars, St. Louis; Edward M. Litin, Rochester, Minn.; Spencer L. Israel, Philadelphia; Julian E. J. Jacobs, Charlotte, N. C.; W. Edward Chamberlain, Washington, D. C.; and Campbell M. Gardner, Montreal, Quebec, Canada. Scientific exhibits are planned, and the meeting is classified for category I credit by the American Academy of General Practice. For information write the Omaha Mid-West Clinical Society, 1031 Medical Arts Building, Omaha 2, Neb.

NEW JERSEY

Symposium on Diabetes.—The New Jersey Diabetes Association in cooperation with the New Jersey State Department of Health will present the sixth annual Symposium on Diabetes Mellitus at the Harrison S. Martland Medical Center, Newark, Oct. 29. The morning session will feature ward rounds and a bedside conference, with Dr. Francis D. W. Lukens of the University of Pennsylvania, Philadelphia, as chief discussant and Dr. Harold J. Jeghers, of Seton Hall College of Medicine, Jersey City, moderator. The afternoon session, a clinical conference, will include the following:

The Arteries and Kidneys in Diabetes Mellitus, Dr. William E. Ehrich, Philadelphia.
Renal Biopsy Pathology in Diabetic Patients, Dr. George E. Schreiner, Washington, D. C.
Problems of Lipid Metabolism in Diabetes, Dr. David Seligson, New Haven, Conn.
Relation Between Diabetes and Obliterative Arteriosclerosis, Dr. Walter Redisch, New York City.

A panel discussion, "Arteriosclerosis, Diabetes and Related Lipid Metabolism," will be moderated by Dr. Jeghers. For information write Dr. Arthur Krosnick, State of New Jersey Department of Health, Trenton 7.

NEW JERSEY

Lectures on Sterilizing Equipment.—Contamination of hospital supplies by their surroundings will be discussed by Dr. Carl W. Walter, associate clinical professor of surgery, Harvard Medical School, Boston, Oct. 21, at Seton Hall College of Medicine and Dentistry, Jersey City. Dr. Walter's paper, entitled "Environmental Sepsis," will be presented from 3-4 p. m. at Murdoch Hall in the Jersey City Medical Center, Jersey City, and will be open to all with a professional interest in the subject.

Conference on Industrial Health.—"The Disturbed Adolescent, Our Future Employee" will be the theme for the New Jersey Industrial Health Conference at Far Hills Inn, Somerville, Oct. 18. The program lists the following:

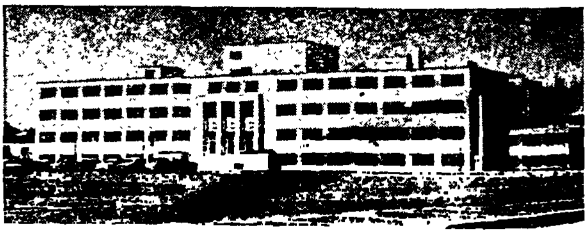
Rehabilitation of the Disturbed Adolescent, Dr. Ralph Brancale, Menlo Park, N. J.
Emotional Factors at Work, Dr. Gerald Gordon, Wilmington, Del.
Problems of Emotional Stability Today, Dr. Joseph M. Tobin, Princeton, N. J.
Medical Research in the Petroleum Industry, Dr. Horace W. Gerarde, Linden, N. J.
Electromyography—Its Value in Low Back Diagnostic Problems (Comparison of Various Diagnostic Techniques), Dr. Earl F. Hoerner, West Orange, N. J.

A disaster demonstration directed by Dr. Thomas F. Nevins Jr., director, Esso Bayway Medical Department, will be conducted at 2 p. m.

NEW YORK

Annual Public Health Lecture.—The ninth Augustus B. Wadsworth Lecture will be given at the Division of Laboratories and Research, New York State Department of Health, Albany, Nov. 20, by Dr. Albert H. Coons, visiting professor of bacteriology and immunology, Harvard Medical School, Boston, on "Stalking with Antibodies." The lectureship was established in 1950 by the staff of the laboratories and the council of the New York State Association of Public Health Laboratories.

Plan Dedication of Research Wing in Buffalo.—The dedication of Sherman Hall, a new research wing of the University of Buffalo School of Medicine, is planned for Oct. 18, 10 a. m. Cost of the T-shaped, four-storied wing was $1,641,000, made possible by a $695,000 grant from the estate of the late Dr. and Mrs. DeWitt J. Sherman, and matching funds from the National Institutes of Health. On the ground floor are physiology research laboratories, high-altitude chambers, isotope rooms, an all-weather room, and machine and electronics shops. On the first floor are student teaching laboratories, neurophysiology and cardiopulmonary research laboratories. The second floor will be devoted to research in bacteriology and immunology. The new department of biophysics at the university will be on the ground floor of the new hall.



The new Sherman Hall of the University of Buffalo School of Medicine.

Personal.—Dr. Stephen C. F. Mahady, former director of the Broadacres Sanatorium, Utica, has been appointed director of the State Out-Patient Chest Clinic at the Broadacres Sanatorium. The Sanatorium, which was turned over to the state in 1948 for use as a tuberculosis hospital, was returned to Oneida County Aug. 15.——Emanuel M. Bogdanove, Ph.D., assistant professor of anatomy, Albany

Medical College, will spend the 1958-1959 academic year in London, England, under the terms of a U. S. Public Health Service traineeship award, studying under Dr. Geoffrey W. Harris, at the Maudsley Hospital, University of London.—Dr. Barbara R. Rennick, assistant professor of physiology, New York State University Upstate Medical Center, Syracuse, has been awarded a Wellcome Foundation fellowship for travel in Europe. She left Syracuse Sept. 1 to return in about six weeks.

New York City

Lecture on Oral Pathology.—The New York Institute of Clinical Oral Pathology has announced the seventh Herman L. Reiss Memorial Lecture to be held at the New York Academy of Medicine Building, 2 E. 103rd St., Oct. 27, 8:30 p. m. Dr. Seymour J. Kreshover of the National Institutes of Health, Bethesda, Md., will lecture on "Prenatal Factors in Oral Pathologic Conditions." Members of the dental, medical, and allied professions are cordially invited.

Dr. Merritt Named Acting Dean at Columbia.—Dr. H. Houston Merritt, director of the neurology service, has been appointed acting dean of the Faculty of Medicine of Columbia University and acting vice-president in charge of medical affairs. In addition to this new post, Dr. Merritt will continue as Columbia's professor of neurology and to direct the neurological service at the New York Neurological Institute.

PENNSYLVANIA

Symposium on Nutrition in Pittsburgh.—"Advances in Human Nutrition," a symposium sponsored by the H. J. Heinz Company as part of a week of ceremonies dedicating the new Heinz Research Center, will be held in Pittsburgh, Oct. 13-14. Speakers will include Charles Glen King, Ph.D., executive director, Nutrition Foundation Inc.; Dr. Alexander Marble, president, American Diabetic Association; Dr. William Henry Sebrell, director, Institute of Nutrition Sciences, Columbia University, New York City; Dr. Nevin S. Scrimshaw, director, Institute Nutrition of Central America and Panama; Floyd S. Daft, Ph.D., director, National Institute of Arthritis and Metabolic Diseases; Dr. Fredrick J. Stare, chairman, department of nutrition, Harvard University; Dr. Eric K. Cruichshank, of the Medical Schools of the University College of the West Indies (Jamaica) and the University of London; and Dr. James M. Hundley, of the United Nations' Food and Agricultural Organization and its International Children's Emergency Fund. Reports will be made on the results of research on these subjects:

Relationship Between Nutrition and the Degenerative Diseases of Middle and Old Age (Especially Arteriosclerosis and Coronary Heart Disease.)
Maternal and Child Nutrition.
Nutritional Treatment of Children Afflicted with Inherited Metabolic Disorders, or "Chemical Diseases."
Basic Biochemical and Nutritional Research.
International Aspects of Malnutrition, with Emphasis on the Under-Developed Areas of the World.

The symposium will feature a panel discussion on nutrition education conducted by E. Neige Todhunter, Ph.D., president, American Dietetic Association, and by medical nutritionists, home economists, and educators. The sessions will be held at the H. J. Heinz Company Auditorium. Guests will tour the laboratories of the new Research Center.

Philadelphia

Symposium of Tuberculosis.—A three-day International Symposium on the Status of Tuberculosis as a Public Danger will be held in Philadelphia Nov. 20-22, at the Bellevue-Stratford Hotel, Philadelphia, under the auspices of Deborah Tuberculosis Sanatorium and Hospital of Browns Mills, N. J. Chairman of the Deborah Symposium Planning Committee is Dr. George N. J. Sommer Jr., of Trenton, N. J., and member of Deborah's medical board. Dr. Sommer said that topics to be discussed include epidemiology, mortality and morbidity changes, case findings programs, bacteriological aspects, prophylaxis including the status of BCG and Isoniazid prophylaxis, surgical aspects of tuberculosis treatment, chemotherapy of tuberculosis, drug resistance, the open negative case and its various implications of public health management. Deborah Tuberculosis Sanatorium, a free and nonsectarian institution, founded 36 years ago, has embarked on an expansion program in the role of a specializing hospital at the frontier of cardiac and pulmonary surgery.

SOUTH DAKOTA

Election of Medical Examiners.—The South Dakota State Board of Medical and Osteopathic Examiners met in August in Rapid City and elected to the presidency for the fiscal year Donald L. Kegaries, M.D., Rapid City; vice-president, Robert A. Buchanan, M.D., Huron; secretary-treasurer, Magni Davidson, M.D., Brookings. Reelected was executive secretary Mr. John C. Foster, 300 First National Bank Building, Sioux Falls, S. D. Other members of the Board include Chester B. McVay, M.D., Yankton.

VIRGINIA

Dr. Cash Appointed Professor in Pakistan.—Dr. James R. Cash, Walter Reed Professor of Pathology, University of Virginia Department of Medicine, Charlottesville, has been appointed professor of pathology at the Basic Medical Science Institute in Karachi, Pakistan. The Basic Medical Science Institute is a new school founded jointly by the Pakistani government, the International Co-operation Administration of the U. S. State Department, and

Indiana University, to train graduates of Pakistani medical schools to become faculty members of their medical schools. Dr. Cash's appointment in Pakistan is for two years, after which he plans to resume his affiliation with the department of pathology at the medical school.

Annual State Meeting in Richmond.—The 111th meeting of the Medical Society of Virginia will be held at the Jefferson Hotel, Richmond, Oct. 12-14. The presidential address will be given by Dr. Harry C. Bates Jr., Arlington, at the opening session. The program includes the following papers by guest speakers:

Present Status of Drugs in Hypertension, Dr. Edward S. Orgain, Durham, N. C.
Oral Hypoglycemic Drugs, Dr. John J. Canary, Washington, D. C.
Genetic Counseling, Dr. Victor C. Vaughan, III, Augusta, Ga.
Neurotic Problems in the Aged, Dr. Ewald W. Busse, Durham, N. C.

Specialty meetings, alumni meetings and banquets, technical exhibits, and a ladies' program are planned. Entertainment includes the banquet Oct. 14, 7 p. m., featuring the installation of Dr. Walter P. Adams, as president. For information write Mr. R. I. Howard, executive secretary, Medical Society of Virginia, 1105 W. Franklin St., Richmond 20, Va.

WASHINGTON

Dr. Kegel Goes to Iran.—Dr. Richard F. C. Kegel, of Aberdeen, has accepted the post of visiting radiologist to the Shiraz Medical Center, Shiraz, Iran, for two years. Dr. Kegel has been in the Near East previously as head of the department of radiology at The American University of Beirut, Lebanon. After his term as visiting radiologist, he will return to his practice in Aberdeen.

Annual Symposium on Heart Disease.—The 10th annual Symposium on Heart Disease, sponsored by the Washington State Heart Association in cooperation with the Washington State Department of Health, will be presented Oct. 17-18 at the University of Washington Health Sciences Building, Seattle, with the theme, "Congestive Heart Failure and Hypertension." Speakers and subjects are:

(1) Concept of Essential Hypertension; (2) Starling's Concepts of Heart Failure in Man, Sir George White Pickering, Oxford, England.
(1) Hemodynamic Effects of Exercise; (2) Response of Hypertensive Patients to Physical Exercise, Dr. Carleton B. Chapman, Dallas.
(1) Clinical-Physiological Correlations of Congestive Heart Failure; (2) Cardiac Output and Congestive Heart Failure, Dr. Lewis Dexter, Boston.
(1) Treatment of Congestive Failure; (2) Natural History of Hypertensive Disease in Man and Hypertension in Giraffes, Dr. James V. Warren, Durham, N. C.

There will be no registration fee. The symposium is approved for category I credit by the American Academy of General Practice. For information write the Washington State Heart Association, 3121 Arcade Building, Seattle 1, Wash.

WISCONSIN

Dr. Bellis Honored.—Dr. Glenford L. Bellis, the only surviving member of the group of 22 men and women who founded the Wisconsin Anti-Tuberculosis Association 50 years ago, was the first recipient of the association's new "award for distinguished service." The award will be made from time to time for "distinguished service to tuberculosis control in Wisconsin."

GENERAL

Annual Public Health Meeting.—The American Public Health Association announces that its 86th annual meeting will be held in St. Louis Oct. 27-31. Scientific sessions will be held in Kiel Auditorium, where scientific and technical exhibits will be on view. More than 40 related organizations are scheduling sessions during the same week. Highlights will include presentation of the annual Ablert Lasker awards of the association and the Sedgwick Memorial Medal. For further information write Dr. Berwyn F. Mattison, 1790 Broadway, New York 19, Executive Secretary.

Fellowship in Medical Neoplasia.—Memorial Center, a training center affiliated with Cornell University Medical College, New York City, which specializes in cancer and allied diseases, offers fellowships to a limited number of graduate physicians. Candidates must be graduates of recognized A. M. A. approved medical schools and must have completed or be in process of completing two years of postgraduate training in internal medicine in addition to one year of internship. They "must be of the highest integrity and moral character" and have an expressed interest, both academic and clinical, in the study of malignant neoplastic diseases. The salary stipend is $6,000 per annum without maintenance. Appointment is for one year normally beginning July first, renewable for one or two years for select individuals. Applicants should apply in writing to: Dr. Lloyd F. Craver, Chief, Medical Neoplasia Service, Memorial Center for Cancer and Allied Diseases, 444 E. 68th St., New York 21.

Applications for Grant in Hematology Research.—The Hematology Research Foundation invites applications for a grant-in-aid for Hematologic Research for a period of one year. Applications must be submitted no later than Nov. 10 to Hematology Research Foundation, 64 W. Randolph St., Chicago 1; nine copies are requested. Application forms for the grants are available on request. Awards will be announced in January, 1959, by the medical advisory board which will choose the applicants on the basis of the proposed research project. The Hematology Research Foundation, a nonprofit organization, provides funds for the research of leukemia, Hodgkins and other blood diseases.

Neuropsychiatrists Convene in Columbus, Ohio.—The 34th annual convention of the Central Neuropsychiatric Association will be held Oct. 17-18, with headquarters at the Deshler-Hilton Hotel, Columbus, Ohio. The presidential address will be given the afternoon of Oct. 17 by Dr. Edward G. Billings, Denver. Fourteen papers are scheduled, and Drs. Hilda R. Knobloch and Benjamin Pasamanick will present movies with their talk on "Behavior and Development in an Infant Gorilla." Presiding at the scientific sessions will be Drs. Martin H. Hoffmann, Detroit, and Hamilton F. Ford, Galveston, Texas. The annual banquet is planned for Oct. 17, 6:30 p. m. A ladies' program is arranged. For information write Dr. Ralph M. Patterson, Secretary-Treasurer, Central Neuropsychiatric Association, The Columbus Psychiatric Institute, University Health Center, Columbus 10, Ohio.

Conference on Tuberculosis in Dayton.—The Mississippi Valley Conference on Tuberculosis will be held Oct. 15-18 at the Biltmore Hotel, Dayton, Ohio. The keynote address will be given by Frank J. Lausche, senator from Ohio. A session on "Radiation Facts and Fiction" will be moderated by Dr. Fred J. Hodges, Ann Arbor, Mich. The following panel discussions and moderators are scheduled:

The '59-ers, Pioneers in Respiratory Diseases, Mr. J. Irvin Nichols, executive director, Michigan Tuberculosis Association, Lansing.
The Independent Agency Fortress of Freedom, Mr. John E. Egdorf, executive director, Tuberculosis Institute of Chicago and Cook County.
This is My Problem, Mr. George J. Kienzle, director, School of Journalism, Ohio State University, Columbus.

The Mississippi Valley Trudeau Society will meet Oct. 17 with Drs. William M. Spear, Oakdale, Iowa, and Harold G. Curtis, Cleveland, presiding at the two sessions. Two panel discussions "Atypical (Anonymous) Mycobacteria" and "Inoperable Pulmonary Neoplasm," will be moderated by Drs. Dieter Koch-Weser, Cleveland, and Virgil A. Plessinger, Cincinnati, respectively.

Physicians Meeting in Louisville.—The Kentucky-Tennessee regional meeting of the American College of Physicians will be held Oct. 18 at the Brown Hotel, Louisville, Ky. The program lists the following:

Diagnosis and Treatment of Mucous Membrane Lesions, Dr. Adolph B. Loveman, Louisville.
Comparison of Chest X-Ray Changes and Pulmonary Function in Chronic Lung Disease, Drs. William H. Anderson, Edsel S. Reed, and Paul O. Wells, Harlan, Ky.
Idiopathic Retroperitoneal Fibrosis and Factor VII Deficiency, Drs. Bernard I. Popham, and Thomas D. Stevenson, Louisville.
Death from Acute Renal Failure—Analysis and Critique, Dr. Walter K. Hoffman Jr., Memphis, Tenn.
The Electrocardiogram in Chronic Cor Pulmonale, Dr. Thomas N. Stern, Memphis.
New Cause of Pseudo Heart Disease, Dr. Maurice S. Rawlings, Chattanooga, Tenn.
Idiopathic Thrombocytopenic Purpura, Drs. Ellis A. Fuller, Louisville, Maxwell M. Wintrobe and George E. Cartwright, Salt Lake City.
Erythrocyte Acetycholinesterase in Paroxysmal Nocturnal Hemoglobinuria, Dr. Robert C. Hartmann and Joseph V. Auditore, Ph.D., Nashville.

Speaker at the banquet (7 p. m.) will be Dr. Charles A. Doan, Columbus, Ohio, first vice-president of the college. All medical residents in the area are cordially invited.

Anesthesiologists Meeting in Pittsburgh.—The American Society of Anesthesiologists will meet Oct. 18-24 in the Penn-Sheraton Hotel, Pittsburgh. Panel discussions planned for Oct. 22 are as follows: Exchange of Water and Electrolytes During the Operative Period; Resuscitation: Pneumatic, Electronic, and Expired Air; Morbidity and Mortality in the Operating Room: Where Lies the Responsibility; The Monitoring of Vital Functions During Anesthesia. Papers by Canadian speakers will include "A Technique for Measuring Concentrations of Fluothane During Closed Circuit Anesthesia with an Infra-Red Analyser," by Drs. Deirdre M. Gillies, James G. Robson, William G. Cullen, and Harold R. Griffith, Montreal, and "Acid-Base Homeostasis During Fluothane Anesthesia," by Dr. Allen B. Dobkin, Saskatoon, Saskatchewan. Luncheon panel discussions will feature Brig. Gen. Donald D. Flickinger, M.C., U. S. A. F., Washington, D. C., speaking on "Biomedical Aspects of Space Flight," and Dr. George T. Pack, New York City, presenting "The Influence of Disease on History." Motion picture sessions and scientific and technical exhibits are planned. Sixty-seven round-table luncheons will be held Oct. 21. For information write the American Society of Anesthesiology, 802 Ashland Ave., Wilmette, Ill.

Regional Physicians Meeting in Hot Springs.—The American College of Physicians Arkansas-Oklahoma Regional Meeting will be held Oct. 18 at the Arlington Hotel, Hot Springs, Ark. Dr. Bert F. Keltz, Governor for Oklahoma, will preside at the opening session at which Dr. John N. Compton, Governor for Arkansas, will present an address. Papers including invited authors are:

The Erythropoetic Factor, Drs. Walter H. Whitcomb and James F. Hammarsten, Oklahoma City.
Activation of the Free Wall of the Right Ventricle in Right Bundle Branch Block, Drs. Loyal L. Conrad and T. Edward Caddy, Oklahoma City.
Milk Alkali Syndrome, Dr. Malcolm W. Davis, North Little Rock, Ark.

Lipid Metabolism in Diabetes, Dr. Allen R. Hennes, Oklahoma City.

Dangers of the Roentgen Ray, Dr. Joseph A. Norton, Little Rock, Ark.

Spotted Fever in Oklahoma: A Clinical and Epidemiological Study, Drs. Harold G. Muchmore and Walter A. Camp, Oklahoma City.

Production of Experimental Gastritis by a Preparation of Human Gastric Juice, Drs. Stewart G. Wolf Jr., William O. Smith, Walter Joel, and Merlin K. Duval, Oklahoma City.

A panel on "Hepatitis" is planned for 4 p. m., moderated by Dr. Richard V. Ebert, Little Rock. At the evening session banquet, with Dr. Compton as toastmaster, guest speaker will be Dr. Dwight L. Wilbur, San Francisco, president of the college.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral Examination.* San Francisco, Sept. 29-Oct. 3, and Phoenix, April 5-10, 1959. The 1959 written examination will be given in various locations in the United States and Canada, July 17. The final date for filing application for the 1959 written examination is six months prior to the examination. There is no filing deadline for oral examinations. Sec., Dr. Curtiss B. Hickcox, 217 Farmington Ave., Hartford 8, Conn.

American Board of Dermatology: *Written. Several Cities,* June 30. *Oral.* Detroit, Oct. 17-19. Final date for filing all applications is April 1. Sec., Dr. Beatrice Maher Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *Written.* Oct. 20, 1958. *Oral.* Chicago, Oct. 13-16. *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the South and Southwest, New Orleans, Feb. 3-6. Final date for filing application is Jan. 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application is Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application is March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application is March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application is Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: Applications for certification, new and reopened, Part I, and requests for re-examination Part II, are now being accepted. All candidates are urged to make such application at the earliest possible date. Deadline date for receipt of application was September 1, 1958. No application can be accepted after that date. It should be noted by prospective candidates that the deadline date in 1959 is August 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written,* qualifying test (Part I), January 1959. Final date for filing application was July 1, 1958. *Oral Examinations 1958* (Part II): Chicago, Oct. 6-10. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 21-23, 1959. Deadline for receipt of applications was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 6-10. Final date for filing application was April 30. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Chicago, Oct. 30-Nov. 1. Final date for filing application was Sept. 30 Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Oral.* Chicago, Oct. 24-26 and New York, Dec. 5-7. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written.* Chicago, Oct. 9-11. Final date for receipt of case reports was July 1. Corresponding Secretary, Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Examination in Public Health.* St. Louis, Oct. 24-26. Final date for filing application was Aug. 15. Sec., Dr. Thomas F. Whayne, 3438 Walnut St., Philadelphia 4.

American Board of Psychiatry and Neurology: New York City, Dec. 15-16; New Orleans, Mar. 16-17. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 will be terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Regular Examination.* Washington, D. C., Dec. 8-11. Final date for filing application was July 1. *Special examination in Nuclear Medicine for those diplomates in Radiology or Therapeutic Radiology.* Washington, D. C., Dec. 6. Final date for filing application was Oct. 1. *Special Examination.* Cincinnati, Mar. 16-19, 1959. Final date for filing application is Nov. 1. Candidates completing training June 30, 1959 are not eligible for the Spring 1959 examinations. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: Written examinations (Part I) will be held at various centers in the United States, Canada, Hawaii, Puerto Rico, and certain military centers abroad on December 3. The date of the Fall examination in *Part I* has been changed from the last Wednesday of October as announced in its current Booklet of Information to December 3, 1958. Thereafter, examinations in Part I will be held once annually, on the first Wednesday of December. The closing date for filing applications will be August 1. *Part II.* Rochester, Minn., Oct. 20-21; Nashville, Tenn., Nov. 17-18; New York City, Dec. 15-16; Houston, Tex., Jan. 12-13; New Haven, Conn., Feb. 9-10; Durham, No. Car., March 9-10; San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: Various centers throughout the United States. *Written.* Spring of 1959. Final date for filing application is December 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Avenue, Detroit 2.

American Board of Urology: *Written Examination.* Twenty-five cities throughout the country, Dec. 5. The oral will be given in Chicago in February 1959. Sec., Dr. William Niles Wishard, Jr., 30 Westwood Road, Minneapolis 26.

GOVERNMENT SERVICES

ATOMIC ENERGY COMMISSION

Atomic Demonstration Visits High Schools in Every State.—Last week, seven panel trucks left the American Museum of Atomic Energy to begin the fourth year of the Atomic Energy Commission's high school demonstration program. With each unit is a manager—a college graduate trained in nuclear energy—and demonstration apparatus including animated panels, charts, a geiger counter, and a Van de Graff generator.

This one-day program is designed to give its young listeners a glimpse of the present and potential uses of atomic energy. First a demonstration-lecture is presented at a regular assembly of the school's entire student body; then the exhibits manager arranges for experiments and discussions for students in their science classes and clubs. A small nuclear science library of books suitable for secondary school students carried with "This Atomic World" is stressed by the manager in his discussions.

Since its beginning in 1955, "This Atomic World" has traveled to high schools in every state and the District of Columbia to stimulate the interest of young people in science and science-teaching careers. The program is made available without charge. The Oak Ridge Institute of Nuclear Studies in Tennessee, a nonprofit corporation of 36 southern colleges and universities, also administers 24 other traveling exhibit units of three major types and operates the American Museum of Atomic Energy for the Atomic Energy Commission.

AIR FORCE

International Symposium on the Physics and Medicine of the Atmosphere and Space.—The United States School of Aviation Medicine has sent out invitations for the Second International Symposium on the Physics and Medicine of the Atmosphere and Space to be held Nov. 10-12 at the Hilton Hotel in San Antonio, Texas. The general subjects of the sessions are environment, planets, vehicles, rescue in space, medical problems, and medical problems of time. Southwest Research Institute, 8500 Culebra Rd., San Antonio, is in charge of the arrangements.

The keynote speech on Monday morning will be delivered by the commandant of the School of Aviation Medicine, Major Gen. Otis O. Benson Jr., on "Common Platform of Physics and Medicine in the Advance of the Vertical Frontier." Among other speakers and chairmen of the sessions will be the following:

Alan T. Waterman, National Science Foundation
Hugh L. Dryden, director, National Advisory Committee for Aeronautics
Marcel Nicolet, head, department of radiation, Meteorological Institute of Belgium
Lieut. Gen. Walter E. Todd, Maxwell Air Force Base, Alabama
Hubertus Strughold, professor of space medicine, U. S. School of Aviation Medicine
Jakob Eugster, University of Zurich, Switzerland
Detlev W. Bronk, Rockefeller Institute of Medical Research, Rochester, N. Y.
Major Gen. Bernard A. Schriever, U. S. Air Force
L. R. Shepherd, president, British Interplanetary Society, London
Wernher von Braun, Army Ballistic Missile Agency, Alabama
Major Gen. Dan C. Ogle, surgeon general, U. S. Air Force
Capt. Langdon Newman, commandant, U. S. Naval School of Aviation Medicine, Pensacola, Fla.
Alberto Hurtado, director, Institute of Andean Biology, Lima, Peru
Siegfried J. Gerathewohl, associate professor of Psychology, U. S. Air Force School of Aviation Medicine
William R. Lovelace II, Lovelace Foundation, Albuquerque, N. Mex.
E. J. Baldes, Mayo Clinic, Rochester, Minn.
Walter O. Roberts, professor of astronomy, University of Colorado, Boulder
Heinz Haber, University of California, Los Angeles.

Held at the close of the geophysical year, this symposium affords an opportunity for the international exchange of information on subjects related to the exploration of space. Attendance is restricted (500) to those directly concerned in the physics and medicine of space. The proceedings will be published in book form.

Personal.—Brig. Gen. Earl Maxwell, M. C., retired Sept. 1, after 30 years' active service. General Maxwell is rated as Chief Flight Surgeon. He is board certified in Ophthalmology and in aviation medicine. After retirement, he will be affiliated with Alcon Laboratories, Fort Worth, Texas.

ARMY

Personal.—Col. Clark B. Williams, M.C., formerly Advisor to the U. S. Military Assistance Advisory Group to the Nationalist Government of China on Taiwan, has been named Executive Officer at Brooke Army Medical Center, San Antonio, Texas. ——Brig. Gen. Carl W. Tempel, M. C., joined the office of the surgeon general in Washington, D. C., on Sept. 1, as chief of the professional division, succeeding Brig. Gen. Sam F. Seeley, who retired from the Army after more than 31 years' service. Dr. Tempel will be responsible for the professional activities of the Army medical service in all general and specialty fields of medical practice. He is certified by the American Board of Internal

Medicine and in the Sub-specialty Board for Pulmonary Disease.—Major Gen. Paul I. Robinson, executive director, Office for Dependents' Medical Care, Army Surgeon General's Office, became Coordinator of Medical Relations for the Metropolitan Life Insurance Company on his retirement on Aug. 31. He was succeeded by his assistant, Col. Floyd L. Wergeland. General Robinson had been executive director of the "medicare" program since it was established in December, 1956.

NAVY

Personal.—Capts. Allan S. Chrisman, Calvin B. Galloway, and Frank P. Kreuz Jr., have been made temporary rear admirals. Captain Chrisman is commanding officer, U. S. Naval Hospital, San Diego, Calif.; Captain Galloway is commanding officer of the U. S. Naval Medical School, National Naval Medical Center, Bethesda, Md.; and Captain Kreuz is commanding officer of the U. S. Naval Hospital, National Naval Medical Center.

The following medical officers, all captains, were retired on Aug. 1, 1958: Robert B. Johnson, Bishop L. Malpass, Donald W. Miller, James R. Reid, Robert B. Simons, Edward F. Slosek, Robert B. Shepardson, and Morris M. Rubin.

PUBLIC HEALTH SERVICE

Grants for Training Health Workers.—Grants and awards totaling almost two million dollars for the training of public health specialists were announced, on Sept. 8, by the Public Health Service. A total of $1,003,410 was awarded to 231 persons, including physicians, engineers, health educators, laboratory workers, dentists, and members of other health professions. These persons will enter colleges and universities throughout the United States this fall for a year of training in public health aspects of their professions. Grants totaling $981,617 also were made to 47 colleges and universities offering courses which prepare registered nurses for beginning positions in public health nursing and to 11 schools of public health for training of students whom the schools select.

This is the third year that public health training funds have been available from the federal government. During the first two years of the program, traineeship grants and awards have financed the training of over 1,000 public health workers. The purpose of the program is to relieve the acute personnel shortage in state and local health agencies.

Influenza Vaccination.—The Public Health Service has recommended consideration of influenza vaccination among groups wishing to guard against absenteeism in their professions or occupations and among those to whom the disease might be an added health risk. There are now ample supplies of influenza vaccine of the polyvalent type, containing immunizing material against the important strains of influenza, including the Asian strain. Vaccination should be planned before the fall season begins. According to Dr. Leroy E. Burney, surgeon general of the Public Health Service, there is no indication at present that widespread attacks of influenza will occur this fall and winter, but there undoubtedly will be some influenza, and vaccination is a prudent measure for certain groups and individuals.

Practicing physicians should be the judges of whether or not to vaccinate individuals. Groups which should be considered for vaccination include hospital staffs whose services are necessary to the care of the sick; groups living in close proximity where influenza could spread rapidly, such as institutions; industrial or service groups, big or small, in occupations where the sudden absence of a sizable part of the force would create serious disruption of the work; and individual patients or groups who have a special risk, such as the aged, the chronically ill, and pregnant women.

MISCELLANEOUS

The Virchow Centennial Lectures.—The Armed Forces Institute of Pathology (AFIP) in Washington, D. C., is celebrating, throughout the year 1958, the centennial of the publication of Rudolph Virchow's "Cellular Pathology," in which Virchow first proclaimed a unified concept of cells as self-reproducing biological entities. The celebration program started on March 3, with the first of a series of five daily lectures presented at the institute at 11 a. m., to which the scientific public in the Washington area were invited as they have been to all of the lectures in this series. The schedule of lectures for the rest of the year is as follows: On Oct. 15, Histochemistry and Cellular Pathology, will be presented by R. D. Lillie, M.D., chief, Clinical Laboratory of Pathology and Histochemistry National Institute for Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Md.; Nov. 12, The Cellular Doctrine in the Framework of Medical Science, by Alfred Plaut, M.D., cardiovascular section, AFIP; Nov. 19, Tumors and Cellular Pathology, by Jacob Furth, M.D., Associate Director of Research, Childrens Cancer Research Foundation, Harvard Medical School, Boston; Dec. 3, The Contributions of Studies on Deficiency States to Cellular Pathology, by R. H. Follis Jr., M.D., chief, nutritional section, AFIP; and Dec. 17, Genetics and Cellular Pathology, by K. M. Brinkhous, M.D., professor of pathology, University of North Carolina School of Medicine, Chapel Hill, N. C.

DEATHS

Forrer, Daniel Atwell Ⓜ Griffin, Ga.; University College of Medicine, Richmond, 1901; died Aug. 13, aged 86.

Fortelka, Frank Louis Ⓜ Riverside, Ill.; Chicago College of Medicine and Surgery, 1917; veteran of World War I; served on the staff of St. Anthony's Hospital in Chicago; died in the Veterans Administration Hospital in Hines Aug. 17, aged 64, of Parkinson's disease.

Fracasse, John Ⓜ San Diego, Calif.; Georgetown University School of Medicine, Washington, D. C., 1935; certified by the National Board of Medical Examiners; veteran of World War II; died Aug. 5, aged 50.

Godschall, Alice Bush, Embreeville, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1928; member of the American Academy of General Practice; on the staff of the Embreeville State Hospital; died in the Chester County Hospital, West Chester, July 29, aged 61.

Graham, Joseph Brown, Birmingham, Ala.; University of Virginia Department of Medicine, Charlottesville, 1928; member of the Medical Association of the State of Alabama; died in the South Highlands Infirmary, Aug. 8, aged 56, of acute pulmonary edema and arteriosclerotic heart disease.

Gray, George Morris, Denver; University of Kansas School of Medicine, Kansas City, 1952; interned at the Presbyterian Hospital in Denver, where he served a residency; served a residency at St. Luke's Hospital; resident in pathology at the Children's Hospital; found dead in his car Aug. 3, aged 34, of an overdose of sleeping pills.

Helmholz, Henry Frederic Ⓜ Rochester, Minn., head of the section of pediatrics at the Mayo Clinic from 1921 to 1946, died in the Methodist Worral Hospital Aug. 19, aged 75, of pulmonary edema and coronary atherosclerosis. Born in Chicago, Dr. Helmholz received a bachelor of science degree from the University of Wisconsin, Madison, in 1902, and that of doctor of medicine in 1906 from Johns Hopkins University, Baltimore, where he also served as a fellow in pathology. From 1907 to 1909 he did graduate work in medicine at the University of Berlin, University of Breslau, and the University of Vienna, returning to Chicago to enter the practice of pediatrics. He was assistant professor of pediatrics at Rush Medical College, Chicago, from 1910 to 1920, medical director of the Infant Welfare Society of that city for the same period, and a member of the Otho S.A. Sprague Memorial Institute for Medical Research from 1912 to 1920. During World War I, Dr. Helmholz served as a consultant in pharmacology to the War Department. On Jan. 1, 1921, he became chief of the section of pediatrics in the Mayo Clinic. He became a senior consultant at the Clinic on July 1, 1946, and reached emeritus status in 1949. He also served as professor of pediatrics in the Mayo Foundation, Graduate School, University of Minnesota, from 1921 to his retirement in 1949. In October, 1951, foundation alumni who were fellows in pediatrics honored him at a dinner. At this time an etching of Dr. Helmholz was presented to the section of pediatrics and copies of the etching given to each guest. Dr. Helmholz was associated with St. Mary's, Colonial, and Worral hospitals. He was the moving spirit in the establishment of the Rochester Child Health Project which attracted public health and social workers throughout the Western Hemisphere and many representatives of health, and allied organizations from abroad to become acquainted with activities in the field of "social" pediatrics. He was a specialist certified by the American Board of Pediatrics and served as its vice-president when it was organized in 1934. In 1935 he was appointed a member of an advisory board of experts for the Laboratory for Child Research established by the Loyal Order of Moose in Mooseheart, Ill. He was chief medical consultant for the United Nations International Children's Emergency Fund in Europe in 1947-1948, a post which took him into many countries. In 1940, he served as vice-chairman of the White House Conference on Children and Youth in a Democracy, as chief consultant to the Mid-Century White House Conference in 1950, and as chairman of the subcommittee on child health of the advisory committee of the U. S. Children's Bureau. He was past-president of the Fifth International Congress of Pediatrics, of the American Pediatrics Society, and of the American Academy of Pediatrics, and an honorary member of many national pediatric societies in Europe and Central and South America. Dr. Helmholz was chairman of the Section on Diseases of Children of the American Medical Association in 1923-1924; an associate member of the American Urological Association; a member of the Northwest Pediatric Society, the American Society of Pharmacology and Experimental Therapeutics, American Physiological Society, the American Association of Bacteriolog-

Ⓜ Indicates Member of the American Medical Association.

ists and Pathologists, the Society for Research in Child Development, the National Research Council, the American Child Health Association, the Alumni Association of the Mayo Foundation, the Society of the Sigma Xi, Phi Beta Kappa, the Alpha Omega Alpha medical honor society, and the Chi Psi academic fraternity. He was also a member of the executive council of the Governor's Committee on Children and Youth of the State of Minnesota, state chairman of the Exceptional Child of the Minnesota Parent Teacher Association, and a member of the Minnesota Council for the Gifted Child. In 1947 he received the National Order of Merit of Carlos J. Finlay, in the grade of comendador, or knight commander, from the Republic of Cuba. In 1951 he was elected first president of the Olmsted County Community Council. In 1952 he was named chairman of the committee on health of the National Congress of Parents and Teachers, and in 1954 he became a member of the executive committee of that organization. In the latter year, he was elected vice-president of the Minnesota Congress of Parents and Teachers. In 1957 he was made a member of the Fifty-Year Club of the Minnesota State Medical Association, and in 1958 he was appointed chairman of the Minnesota State planning committee for the 1960 White House Conference on Children and Youth. In 1943 he was awarded the honorary degree of doctor of science by the University of Wisconsin in Madison, and from 1917 to 1922 he was editor-in-chief of the *American Journal of Diseases of Children*, serving as associate editor after 1926.

Hoermann, Rudolph Bernhard, Milwaukee; Chicago Homeopathic Medical College, 1899; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; on the staff of St. Joseph's Hospital; died Aug. 4, aged 85, of heart disease.

Holland, Harry Albert, Mantoloking, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1917; an associate member of the American Medical Association; member of the Medical Society of the State of Pennsylvania; fellow of the American College of Physicians; served on the staffs of the Chestnut Hill Hospital in Philadelphia and the Point Pleasant Hospital in Point Pleasant, where he died Aug. 9, aged 65, of coronary disease.

Irvin, James, Santa Barbara, Calif.; Medical College of Ohio, Cincinnati, 1909; died July 15, aged 77, following an operation on the gallbladder.

Joelson, Morris Samuel Ⓜ Paterson, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1906; consultant in obstetrics at Barnert Memorial Hospital; died in Deal Aug. 20, aged 74, of cancer.

Jones, Donald Jack Ⓜ Sacramento, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1936; veteran of World War II; died in the Lakeside Hospital in Cleveland Aug. 7, aged 48, of coronary heart disease.

Knight, Durell Keeling, Kansas City, Kan.; University of Kansas School of Medicine, Kansas City, 1924; member of the Kansas Medical Society; veteran of World Wars I and II; on the staff of Bethany Hospital and St. Margaret's Hospital, where he died Aug. 4, aged 63, of coronary insufficiency.

Lo Popolo, Vincent Charles Ⓜ Cross City, Fla.; College of Physicians and Surgeons, Boston, 1947; died Aug. 2, aged 43.

Luhr, Alfred Francis, Buffalo; Jefferson Medical College of Philadelphia, 1905; specialist certified by the American Board of Ophthalmology; an associate member of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; associated with Mercy, Buffalo General, and Sisters of Charity hospitals; died in St. Marys, Pa., Aug. 4, aged 78.

McMillan, Walter Ree, Dallas, Texas; Meharry Medical College, Nashville, Tenn., 1909; died Aug. 5, aged 84.

Mahon, George Dixon Ⓜ Dallas, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1913; member of the founders group of the American Board of Surgery; member of the Southern Surgical Association; fellow of the American College of Surgeons; served on the staffs of the Baylor University Hospital and Medical Arts Hospital; at one time on the staff of the Mayo Foundation in Rochester, Minn.; founder of the Dallas–Garland Airport; died Aug. 4, aged 65, of the Adams–Stokes syndrome.

Mayfield, George Franklin, Austin, Texas; St. Louis College of Physicians and Surgeons, 1906; died Aug. 4, aged 75, of cerebral hemorrhage.

Mayfield, Hugh F., Huttig, Ark.; Gate City Medical College, Texarkana, Ark., 1906; member of the Arkansas Medical Society; died July 30, aged 78, of ruptured aortic aneurysm.

Meek, Charles Roscoe Ⓜ Lorain, Ohio; Starling–Ohio Medical College, Columbus, 1913; member of the American Academy of General Practice; at one time supervisor of the public schools of Lorain; served as medical examiner and surgeon for the National Tube Division, Lorain Works; formerly health commissioner of Lorain; past-president of the staff of St. Joseph's Hospital; died Aug. 2, aged 71.

Milloy, Frank Joseph Ⓜ Phoenix, Ariz.; Northwestern University Medical School, Chicago, 1920; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; formerly secretary of the Arizona State Medical Association; charter member of Blue Cross and Blue Shield; chief of staff, St. Joseph's Hospital; affiliated with all the local hospitals; served as editor of *Arizona Medicine;* died Aug. 4, aged 64, of pulmonary lung tumor with pneumonitis.

Noble, Guy Eugene Ⓜ St. Marys, Ohio; Starling Medical College, Columbus, 1905; served as councilor of the Third District of the Ohio State Medical Association; chairman of the board of governors and chief of staff, Joint Township District Hospital; member of the staff, St. Rita's and Memorial hospitals in Lima; served as health officer; died Aug. 4, aged 77, of congestive heart failure.

Noon, Russell Alleyne, Johnstown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1924; chief on the medical service, Conemaugh Valley Memorial Hospital; associated with the Johnstown Memorial Hospital, where he died Aug. 4, aged 59, of arteriolar nephrosclerosis and hypertension.

Novello, Joseph Albert Ⓜ Elizabeth, N. J.; Georgetown University School of Medicine, Washington, D. C., 1932; member of the Industrial Medical Association; veteran of World War II; formerly member of the city board of education, affiliated with Alexian Brothers, Elizabeth General, and St. Elizabeth's hospitals; died in Millington Aug. 6, aged 52, of cancer of the intestine.

Phipps, George Wilson Ⓜ Caruthersville, Mo.; Hospital College of Medicine, Louisville, 1902; veteran of World War I; died Aug. 5, aged 78.

Sawyer, John Brewster Ⓜ El Cerrito, Calif.; St. Louis University School of Medicine, 1943; member of the American Academy of General Practice; veteran of World War II; on the staffs of the Alta Bates and Herrick Memorial hospitals in Berkeley; died Aug. 5, aged 43, as the result of a mid-air glider collision.

Sears, Henry Clark, Binghamton, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1906; an associate member of the American Medical Association; served as chief medical inspector for the Binghamton school system; formerly on the staff of the Binghamton City Hospital; died Aug. 5, aged 77, of cerebral hemorrhage.

Sellards, Joseph Walter Ⓜ Clarinda, Iowa; Drake University Medical Department, Des Moines, 1901; veteran of World War I; on the staff of the Clarinda Municipal Hospital, where he died Aug. 3, aged 83, of bronchopneumonia and uremia.

Sparks, Samuel M. Ⓜ New Kensington, Pa.; Jefferson Medical College of Philadelphia, 1927; member of the Industrial Medical Association; fellow of the International College of Surgeons and the American College of Surgeons; senior surgeon at Citizens General Hospital, where he died Aug. 4, aged 58, of sarcoma of the lower spine with metastasis to the lungs.

Stack, Robert Anthony Henry Ⓜ Lorain, Ohio; University of Cincinnati College of Medicine, 1920; fellow of the American College of Surgeons; veteran of World War I; member of the board of health of Lorain; associated with St. Joseph's Hospital, where he died Aug. 4, aged 63.

Stomberg, Carl Winfred Ⓜ Seattle; University of Minnesota Medical School, Minneapolis, 1925; formerly health officer of Everett; drowned Aug. 2, aged 56, while water skiing on Lake Stevens.

Swift, Earle Reed Ⓜ Lakeview, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; on the staff of the Kelsey Hospital, where he died Aug. 5, aged 85, of coronary thrombosis.

Thompson, Cleveland Ⓜ Waynesboro, Ga.; University of Georgia Medical Department, Augusta, 1909; fellow of the American College of Surgeons; past-president of the Medical Association of Georgia; on the staff of the Burke County Hospital; died Aug. 5, aged 74.

Walker, Joseph Edison, Memphis, Tenn.; Meharry Medical College, Nashville, Tenn., 1906; chairman of the board of Universal Life Insurance Company; president of the Tri-State Bank of Memphis; shot and killed by an acquaintance July 28, aged 78.

Wiesenfeld, Paul Cholmar, Perth Amboy, N. J.; L. R. C. P., Edinburgh, L. R. C. S., Edinburgh, and L. R. F. P. & S., of Glasgow, 1940; member of the American Academy of Orthopaedic Surgeons; specialist certified by the American Board of Orthopaedic Surgery; on the staffs of the New Jersey Orthopaedic Hospital in Orange, South Amboy (N. J.) Memorial Hospital, Roosevelt General Hospital, Metuchen, and Perth Amboy General hospitals; orthopedic consultant at Somerset Hospital, Somerville; died Aug. 9, aged 43, of coronary thrombosis.

Ziegler, William Henry Ⓜ Boonville, Mo.; Northwestern University Medical School, Chicago, 1922; served as pediatrician for the division of child hygiene, state board of health; on the staff of St. Joseph Hospital, where he died Aug. 3, aged 66, of acute myocardial infarction.

FOREIGN LETTERS

BRAZIL

Endocervicitis and Sterility.—Dr. J. S. Goes (*Anais da maternidade de São Paulo,* August, 1958) analyzed the factors modifying the receptivity of the cervical mucus to spermatozoa and the interference it offers to the migration of the sperms. He pointed out the necessity of maintaining the organic and functional integrity of the cervical mucogenic glands. This is destroyed by high cervical amputations and by conization and electrocoagulation of the cervical canal. In the presence of endocervicitis, the repeated intracervical application of such antibiotics as oxytetracycline was recommended.

Mammary Sarcoma.—At the Central Cancer Hospital in São Paulo, 10 mammary sarcomas were observed in a series of 754 malignancies of the breast. Dr. Silva Neto and co-workers (*Revista paulista de medicina,* vol. 52, June, 1958) stated that the mean age of the patients was 45.2 years, which is less than that for carcinoma of the breast. Discharge from the nipple was not observed in any of the patients. The chief complaint in all was a lump in the breast. Five of the tumors were fixed to the skin, and in two there were ulcerations. Four were fibrosarcoma, two liposarcoma, two rhabdomyosarcoma, one malignant mesenchymoma, and one cystosarcoma phylloides with malignant changes. This latter spread out to the axillary nodes. Postoperative irradiation was given those with lymph-node metastasis. The prognosis is better in patients with sarcoma than in those with carcinoma of the breast.

Segmentary Aortic Stenosis.—Dr. Nairo Trench and co-workers (*Arquivos da Santa Casa de São Paulo,* June, 1958) restricted the term "coarctation" to congenital cases of aortic stenosis. For acquired cases they preferred the term "segmentary or circumscribed stenosis." They observed three patients with segmentary aortic stenosis in an atypical location. Their symptoms strongly suggested coarctation of the aortic isthmus. Two of these patients were operated on with the latter diagnosis and only at operation was the atypical location and the acquired nature of the stenosis demonstrated. In the first patient, a 30-year-old man, the stenosis was localized in the abdominal aorta, above the renal arteries. It was impossible to verify with certainty the nature of the lesion. The second, a 5-year-old girl, was operated on with the diagnosis of isthmic coarctation. During the operation a segmentary stenosis of the diaphragmatic section of the aorta was found. The patient died in cardiac decompensation and at the autopsy and histological examination an acquired inflammatory process of rheumatic origin was found. In the third patient, a 16-year-old girl, the angiocardiographic signs also confirmed the clinical diagnosis of an isthmic coarctation. Operation revealed extensive alterations of the thickened aortic arch. The aortic pulsations were greatly diminished. It was impossible to resolve this situation by surgery. The patient died and the autopsy and histological findings revealed the rheumatic origin of the stenosis.

Strongiloidiasis.—The results obtained in the treatment of 20 patients with strongiloidiasis were reported by Drs. José Asfora and Maria Maranhão (*Revista brasileira de medicina,* May, 1958). The treatment consisted of introducing into the duodenum, by means of a duodenal tube, 60 Gm. of Panemax in 250 ml. of distilled water, followed by an ampul of hyaluronidase; two or three minutes later 40 ml. of a 1% solution of gentian violet was given. The Panemax, which contains papain, was given to dissolve the excess of duodenal mucus so as to permit a more direct action of the gentian violet on the worm, and the hyaluronidase was given to promote a wider diffusion of the dye, thus bringing it into a more intimate contact with the worm. Four of the patients vomited after the introduction of the medicine, but 12 of the remaining 16 were cured. This is a better rate of cure than has been obtained with other methods of treatment. Patients who were also suffering from ascariasis were also cured of this infestation. This was due to the action of the piperazine contained in the Panemax.

Cancer of the Hypopharynx.—Dr. J. F. Barbosa reported a series of 59 patients with cancer of the hypopharynx in the February issue of *Revista brasileira de cirurgia.* About 90% were located in the pyriform sinuses. These cancers constituted 52% of the malignancies of the pharynx and 5.3% of those of the upper respiratory system seen. Hypopharyngeal and laryngeal cancers were seen in a ratio of 1:1.8. Only 5% of the patients were women; 32% were chronic alcoholics; and 26% were heavy smokers. In 12.5% the Wassermann test was positive. The right pyriform sinus was more frequently affected (35) than the left (18). Of the 59 patients, 4 had cancers in other portions of the upper respiratory system. The highest incidence was in the group aged 50 to 59 years (25 patients); 49 had epidermoid (squamous cell) carcinoma, 7 anaplastic cell carcinoma, 1 basal cell carcinoma, 1

The items in these letters are contributed by regular correspondents in the various foreign countries.

adenocarcinoma, and in 1 no biopsy was performed. Twenty-five tumors were located in the upper portion of the pyriform sinus, 15 in the lower portion, 16 in both, 4 in the posterior wall of the hypopharynx, and 1 in the retrocricoarytenoid region. Clinical symptoms of metastasis in the neck were found in 49 of the patients when first seen, and in 16 of these they were bilateral. In 20 patients that were operated on, lymph node metastases were found in the surgical specimen. In 15 they were located on the same side as the tumor, in 4 they were bilateral, and in 1 they were on the opposite side; 42 of the patients had had symptoms for less than six months when first seen; 35 complained of pharyngeal pain; 31 had a history of enlarged cervical lymph nodes; 29 were hoarse; 14 had pain radiating to the ear; and 8 had hoarseness with dyspnea. Routine inspection and endoscopic examination give enough data for the clinical evaluation of the disease. Roentgenography shows the extension of the tumor to the esophagus and the depth of the infiltration to the surrounding tissues. Resection alone or combined with postoperative irradiation gives the best prognosis. Resection should be en bloc, removing in continuity the primary lesion together with the cervical lymph nodes and tissues. A conservative operation should be performed on tumors of the posterior wall of the hypopharynx and for small lesions of the lateral wall.

Varicose Veins.—Dr. E. B. Ribeiro (*Portugal médico,* June, 1958) pointed out that stasis of the venous circulation at the level of the common iliac vein causes varicose veins in the legs. For this reason direct treatment of the varicose veins is only a palliative measure and sooner or later the varicosities will recur. For the effective treatment of varicose ulcers, phlebectomy is essential.

FRANCE

Arteritis.—J. Patel and co-workers (*Presse méd.* 66:1245, 1958) studied 186 cases of arteritis and concluded that the emergency treatment of acute ischemia and exacerbations, with or without initial development of necrosis, is based on continuous intravenous infusions or intra-arterial infiltrations of heparin and vasodilators. The earlier surgical treatment is performed the better. It must be followed by close supervision, and the use of vasodilators parenterally in the event of recurrence. Relapses can be prevented by the use of anticoagulants.

Hypoglycemic Sulfonamides. — A. Loubatieres (*Presse méd.* 66:1175, 1958) reported that hypoglycemic arylsulfonamides show a selective tropism for the pancreas. They have no action in the absence of the pancreas or insulin. They stimulate the secretion of endogenous insulin, starting from the β-cells of the islands of Langerhans. They potentiate the effects of exogenous and endogenous insulin and facilitate the formation of new functioning β-cells. The possibility of an antienzymatic action of the substances is not proved. When properly used these sulfonamides make available to the body a complement of endogenous insulin. Some patients seem to benefit from the stimulative action of these drugs on the β-cells. Through such a mechanism a lasting remission of human diabetes may be possible.

Postpuerperal Cerebral Thrombophlebitis.—A. Guicheney and co-workers (*Presse méd.* 66:1158, 1958) studied a series of seven patients with postpuerperal cerebral thrombophlebitis in which two died. The authors concluded that an acute cerebral accident with Jacksonian convulsions occurring in the puerperium should call attention to the possible presence of cerebral thrombophlebitis, especially if eclampsia or embolism can be ruled out. The location of the thrombosis and its gradual extension determine the clinical manifestations. Anticoagulant treatment contributed to the healing of those patients on whom it was used.

Simple Goiter.—L. De Gennes (*Presse méd.* 66:1183, 1958) stated that if by the term simple goiter is meant an increase in volume of the thyroid not accompanied with hyperthyroidism or malignant changes, this type of goiter is the result of a hypersecretion of pituitary thyrostimulin. Most of such goiters are amenable to treatment with thyroxin and its derivatives. In such cases the essential point is not to mistake an exophthalmic goiter for a simple goiter. In a few patients operation may be indicated for cosmetic reasons. If thyroidectomy is performed a large portion of the active tissue should be spared in order to prevent myxedema. In the case of a hard and fibrous goiter of long duration, it is essential not to overlook the possibility of a thyroid carcinoma.

INDIA

Amebiasis.—D. D. Bamji and co-workers treated 95 patients who had amebiasis with two new 4,7-phenanthrolinequinone derivatives known as 11,925 and 11,925C (*Current Medical Practice,* vol. 2, June, 1958). These patients were diagnosed clinically and the diagnosis was confirmed by examination of stools, sigmoidoscopy, and smears from the sigmoidal mucosa. Eighty-four patients had intestinal and 11 had hepatic amebiasis, and 40 patients were treated with 11,925 and 55 with 11,925C. Their ages ranged from 13 to 70 years. The duration of symptoms, particularly frequency of stools, varied from less than 10 days to 1 year or more. Some gave a history of past attacks. The stools contained trophozoites in 55 patients, cysts in 30 and both in 10; 78 had abdominal pain, 23 had weakness and prostration, 15 had marked dehydration, and 4 had fever. Of the 11 with hepatic involvement, 10 had a palpable liver. Only 12 on sigmoidoscopy showed a normal mucosa, the rest showing congestion or ulcers.

Forty patients with intestinal amebiasis were treated with 11,925 and 55 (44 with intestinal and 11 with hepatic involvement) were treated with 11,925C. The total duration of treatment varied from 6 to 15 days. The preparations were available in the form of tablets, 100 mg. each of 11,925 and 50 mg. each of 11,925C. The former was used in a daily dose of 600 mg. divided into three equal doses. The daily dose of the latter varied from 300 to 600 mg. daily in three divided doses, depending on the severity of the condition and whether the infection was intestinal or hepatic. The total amount of the drug used varied from 3 to 10 Gm. of 11,925 and 1.5 to 9 Gm. of 11,925C. The results on the whole were satisfactory. Symptoms were relieved within a few days of treatment, followed soon by disappearance of the parasite from the stool and healing of intestinal ulcers. The 11,925 was more effective than 11,925C in patients with intestinal amebiasis and results were better in patients who showed the vegetative form in the stools than in those with cystic forms. In all patients with hepatic amebiasis, 11,925C was used and the results were good in 8 of the 11, as judged by regression in the size of the liver, relief of pain, improvement in toxemia, general condition, and appetite. In patients who had hepatitis with parasites in the stool, the latter disappeared in the course of treatment. Both preparations were well tolerated. Vomiting occurred in only two patients.

Kyasanur Forest Disease.—T. H. Work (*Journal of the Indian Medical Association*, vol. 31, Aug. 1, 1958) reported that a virus belonging to the Russian spring-summer group was isolated from man and monkeys suffering from a prolonged febrile illness in a district in Mysore State which has been called Kyasanur forest disease. The disease is mainly an affection of the hemopoietic and visceral organs rather than the central nervous system, as is the disease caused by Russian spring-summer viruses. The blood serum showed the presence of this virus at least 2 days prior to the onset and through the first 10 days of the disease. The tissues involved from which the organism was recovered were the heart, skeletal muscle, lung, liver, spleen, and kidney, but not the human brain. The cerebrospinal fluid showed the virus on a few occasions when the blood concentration of the virus was very high. The laboratory diagnosis is based on isolation of the virus from the blood serum in the first 10 days of the disease and demonstration and development of a rising titer of specific complement-fixing and neutralizing antibodies in suspected cases where no virus could be isolated. Although man-to-man transmission has not been observed, the virus is highly infectious. Thus, nine infections occurred in the professional and technical personnel of the Virus Research Center in Poona in the eight-month period of investigation of the disease, and two infections occurred in laboratories of the Rockefeller Foundation in New York. Two infections have been known to occur in persons showing demonstrable antibodies in the serum.

R. L. Rao in another article in the same issue described the clinical features of the disease. The onset is sudden with a headache and chill. The headache is severe and frontal in type and accompanied by aching of the whole body. This is followed by fever which rises rapidly to about 103 F (39.44 C). The temperature is continuous, lasting 5 to 12 days. Most patients show suffusion of the palate with maculopapular hemorrhagic spots. Severe prostration, out of proportion to the duration of the disease and extent of the fever, is present. Gastrointestinal symptoms may appear from the onset and hemorrhagic complications may occur in the middle of the first week. Death may occur within 8 to 12 days of the onset. In severe cases, listlessness, dyspnea, slurring speech, and tremors indicate a grave prognosis. Coma sets in eventually and may last for 12 hours. Those who recover continue to be weak over a long period. The leukocyte count is lowered but gradually returns to normal with recovery. The urine shows albumin and granular casts.

Rheumatoid Arthritis.—K. K. Sikka reported a series of 100 consecutive patients with rheumatoid arthritis (*Current Medical Practice*, vol. 2, June, 1958). The patients were subjected to one week of bed rest and given a vegetarian diet containing 344 Gm. of carbohydrate, 75 Gm. of protein, 60 Gm. of fat, and a very small amount of sodium chloride. The ages of the patients ranged from 9 to 50 (average 30) years, and 68 of the patients were in the age group 21 to 40 years; 70 were manual workers and 90 had to work in a fixed posture (60 sitting and 30 standing). The sitting posture was found to be more important than the nature of the work or the standing posture as a causative factor; 78 had to work in damp surroundings throughout the year; 76 were used to a vegetarian diet; and 60 were accustomed to taking an excess of salt with their meals. A history of arthritis in the family was given by 54 patients; 25% of the fathers, 16% of the mothers, and 13% of the siblings of these patients also suffered from arthritis. The common diet and other environmental conditions might be partly responsible for the familial incidence. The prognosis, however, was not influenced by a family history of rheumatoid arthritis.

A septic focus in the paranasal sinuses, teeth, tonsils, or middle ear was observed in 44 and gave a history of some major infectious, allergic, or venereal disease. Any association with rheumatic fever or recognizable endocrine disorder was much less frequent. Some type of postural deformity such as dorsal kyphosis or forward stoop was observed in 34. Seventy had had symptoms for two years or less before they came for examination. Seventy gave a history of some severe emotional trauma. Of the 40 female patients, 32 were married before the age of 18 and the fertility rate was 63.1. Thirteen did not have any children. A history of some change in the menstrual function before the onset of arthritis was available in 21 of the women; menopause had been reached in 4, and the rest did not show any relation between menstrual function and onset of the disease. A clear-cut history of peripheral circulatory disturbance including cold hands and feet, perspiring hands and feet, blanching of fingers, and chilblain was present in 80 of the patients. The onset was insidious in 75, and 76 complained of some prodromal symptoms such as undue fatigue, loss of appetite, loss of weight, or transient pain in joints. The joints to be involved first were those of the hands, feet, wrists, and ankles, followed by knees, elbows, shoulders, and hips. The joints of the right side of the body were involved first in 75. The skin was red in 74 and hot in 76. Periarticular swelling was present in 70, effusion in 40, marked wasting of muscles in 26, ulnar deviation in 20, and bony ankylosis in 8. Fifty-five were underweight and 10 overweight. Seven had associated disease in other systems than the locomotor. In 51 patients the severity of the disease varied with the weather, being worse in cold wet weather.

The urinary excretion of 17-ketosteroids was below normal in most of the patients in this series and there was a progressive decline in its level with progress of the disease. The uric acid-creatinine ratio was within normal limits in 60 of the patients, less than normal in 29, and higher than normal in 11. The total leukocyte count was within normal limits but the eosinophils tended to increase both in relation to rheumatoid activity and duration of illness; 58 had microcytic anemia; 10 had macrocytic anemia; and 32 had no anemia. The sedimentation rate was markedly raised in 82 at the time of the first examination, slightly increased in 8, and normal in 10. The total serum proteins gave almost normal values but the globulin fraction was increased with reversal of the albumin-globulin ratio in some. The serum uric acid was normal. Radiological examination in 72 revealed such abnormalities as osteoporosis, narrowing or widening of joint spaces, and bony ankylosis.

All patients were subjected to artificial fever therapy by means of intravenous injection of triple typhoid vaccine. Blood specimens were collected before and four and eight hours after these injections for estimation of absolute eosinophils and uric acid-creatinine ratio, and 24-hour specimens of urine were collected for estimating the excretion of 17-ketosteroids. Of the 100 patients, 74 were greatly benefitted by fever therapy. Particularly good results were seen when the vaccine was given in the early stages. The level of 17-ketosteroids in the urine increased in almost all patients. The absolute eosinophil count fell immediately after pyrexia and returned to its original level within 24 to 48 hours. The urinary uric acid–creatinine ratio increased after the pyrexia and then returned to its initial level. Some of the untoward reactions of this therapy were herpes, nausea, headache, vomiting, jaundice due to a coincident infectious hepatitis, and muscle cramps. There was no death following fever therapy, and serious complications such as circulatory collapse and delirium did not occur.

Tetanus.—S. R. Kamat and co-workers (*Current Medical Practice*, vol. 2, June, 1958) stated that in the treatment of severe cases of tetanus, although the value of muscle relaxants is recognized, none of the existing relaxants can be considered ideal. They used gallamine triethiodide in a series of 14 patients. The drug was given intramuscularly except in severe cases when it was given intravenously, especially for the first few days after admission. After a small test dose, the optimum dose for each patient was reached by gradually increasing the amount of the drug a few milligrams at a time. The optimum dose was repeated at four to six hourly intervals. As the rigidity diminished after some days of treatment, the dose was gradually tapered off. On an average, the dose ranged from 40 mg. every six hours to 60 mg. every four hours. Chlorpromazine was given simultaneously as it is believed to enhance the action of gallamine triethiodide and reduces the requirements of sedatives to a minimum. It was given orally or intramuscularly in a dosage of 25 to 50 mg. every six to eight hours.

None of the patients was found to be sensitive to gallamine. Sometimes manifestations due to overaction appeared in the form of cyanosis and shallow breathing which was treated by intravenous injection of 0.6 mg. of atropine followed by 0.5 to 1 mg. of prostigmine intravenously. In a few patients the prostigmine had to be repeated every 15 minutes for two or three doses. In addition the patients received 200,000 to 300,000 I. U. of antitetanic serum intravenously, barbiturates intramuscularly every 6 to 12 hours, and penicillin intramuscularly every 6 hours. Oral feeding was preferred, with some patients requiring intravenous fluids. A fluid intake of 2,250 to 3,000 cc. per day was maintained in all patients. Of the 14 patients, 10 had the severer type and of these 5 died (3 of pulmonary complications, 1 of spasms and exhaustion, and 1 of toxemia). The four with the milder type all recovered. The chief advantage of gallamine was the satisfactory relaxation with adequate and natural respiration in most of the patients. Artificial respiration had to be used only in one patient for a short period. Even those who died lived longer than was expected, and this could be attributed to the action of the drug. The points in favor of this drug are the significant reduction in mortality, satisfactory control of rigidity, and absence of cumulative action.

Treatment of Burns.—Patrao and Narayan (*Current Medical Practice,* vol. 2, June, 1958) treated 10 burned patients with intravenous injections of 6% polyvinyl pyrrolidine and local applications of a sulfothiourea gel after initial blood transfusions and intravenous fluids to counteract acute shock. They compared the results with those in a group of 10 controls treated with blood transfusions, dextrose solution intravenously, and local dressings with cod liver oil, sulfonamide ointment, or penicillin cream. The polyvinyl pyrrolidine was used to prevent the development of toxemia and secondary shock. Patients with burns involving less than 65% of the body surface were selected because those with burns involving 80% or more of the body surface invariably died within two days due to severe shock. In the trial series, there was rapid development of healthy granulation tissue, slough was minimal, and skin grafting could be resorted to earlier than in the controls. Pseudomonas aeruginosa infection was seen only in the control series. Patients in the trial series received only penicillin, none of the broad-spectrum antibiotics being found necessary. Their temperature was between 99 and 100 F (37.2 and 37.7 C) and came down to normal within two to three days, while most of the patients in the control group had to be given broad-spectrum antibiotics to control the toxemia and high fever developing from the fourth day on. Convalescence was shorter with the use of the solfothiourea gel locally. The polyvinyl pyrrolidine was given subcutaneously combined with hyaluronidase in children with no untoward results. Thus as compared to the control group, wound healing was more rapid, toxemia was less marked, and stay in hospital was shortened.

Epinephrine, Morphine, and Strychnine.—B. C. Bose and co-workers (*Indian Journal of Medical Research,* vol. 46, March, 1958) studied the pharmacological activity of the hydrochloride, citrate, and tartrate of epinephrine; the hydrochloride, sulfate, and tartrate of strychnine; and the hydrochloride, sulfate, meconate, and tartrate of morphine. The assay was carried out by determining the pressor effect with epinephrine in cats, the analgesic and respiratory depressant effect with morphine in rats and dogs, and the convulsant action with strychnine in frogs. Of the salts of epinephrine, tartrate had the maximal, citrate the intermediate, and hydrochloride the minimal pressor effect, when equimolecular doses of the salts were used. With morphine also, tartrate had the maximal analgesic and respiratory depressant action. With strychnine, the citrate and tartrate had more convulsant action than the hydrochloride, which was the mildest. On analysis of these results in relation to the molecular weights of the salts, it was noted that the molecular weight had some relationship with the pharmacological action. Thus with morphine, the molecular weight and the analgesic potency were proportionate to each other, although such other physical properties as solubility, permeability, alkalinity, ionization constant, and optical rotation may determine the potency of a particular salt.

JAPAN

The Pay of Physicians.—A barber earns 50 cents in less than an hour but the government pays the physician less than 16 cents to examine a patient and make a urinalysis. The medical society has been up in arms for a number of years demanding a revision of medical fees. The insured and the government, however, resist stubbornly any increase in these fees. After numerous conferences the medical profession has finally obtained an 8% increase in the fees, an amount far less than what was demanded. The health insurance works under a complicated system. Each family head is fully insured and the premium is deducted from his pay while the other members of his household are but 50% insured; that is, when medical care becomes necessary for them they are required to pay half of the total cost. To be half insured, an adult pays about 20 cents per person, per month.

Birth Control.—Having had severe setbacks in World War II in pharmaceuticals, Japan welcomes the opportunity of becoming a pilot plant in researches relative to birth control. Dr. Hayashi stated that a new synthetic corpus luteum-like substance changes the character of the uterine secretion in a way that blocks the entrance of sperms, renders the endometrium inhospitable for the implantation of fertilized ova, and makes the oviducts difficult of passage. Upon the heel of this report comes the news that the death rate has nearly balanced the birth rate, leaving no appreciable increase in population. This has been achieved by a wider dissemination about contraceptive techniques and by authorized interruption of pregnancies. The latter method was not without such untoward complications as sterility, unrelieved pelvic disorders, neuroses, and chronic invalidism. For this reason a noted gynecologist has urged physicians to take the uterine curettes out of their instrument cases and throw them away.

The indications for abortion in Japan include poverty and illegitimacy as well as unfitness to bear a child. The credulous public does not have an adequate appreciation of the dangers associated with abortion. It is erroneously supposed by some to be as simple as the extraction of a tooth. Unless the health or life of the mother is in jeopardy an abortion should not be undertaken. A first pregnancy especially should be carried through to completion even in the face of pending divorce, although the law legalizes abortion under such circumstances. If the husband is ill and unable to provide for the family, the wife who tries to help by working should be given a sympathetic understanding by her relatives. If, despite efforts to prevent conception, pregnancy occurs, for her to seek an abortion may not be the best solution. She should bear the first child for the sake of family happiness. If relatives are unable to help, aid may be obtained from a maternity home. Improvement of this situation is a Herculean task, but a contraceptive drug that can be taken by mouth may provide the solution. The post-war slogan in Japan is "Birth control or procreate and starve."

SWEDEN

Dihydrostreptomycin and Penicillin.—Dr. G. Nilsson (*Svenska läkartidningen*, June 27, 1958) treated several thousand patients who had acute infections of the throat, nose, and ears with a combination of dihydrostreptomycin and penicillin (Streptopenin). This combination was given daily for six days irrespective of any reduction in fever. The total dose of dihydrostreptomycin was 3 Gm. for adults, 2.25 Gm. for children between 10 and 15, and 750 mg. for those under 5. In the spring of 1958 the patients who were thus treated (within the age ranges of 7 and 40) in earlier years were subjected to audiometric tests. None of the 771 thus tested showed any impairment of hearing traceable to the Streptopenin. This combination has such a broad spectrum that it covers about 90% of the pathogenic bacteria hitherto isolated. The preference shown for dihydrostreptomycin as compared with streptomycin in this connection is due to the fact that the former is less likely to provoke allergic complications in the patients and hospital staff, but for prolonged treatment or when pushing the dosage above the safe limit it may be wiser to use streptomycin.

Import of Physicians.—The decision in June by the government to import a new lot of Austrian physicians in order to combat the present shortage has drawn protests from the Swedish Medical Association. In 1950, when the first lot of Austrian physicians was imported, Sweden, with a population of 7 million, had about 4,900 physicians. By June, 1958, there were about 6,500 in addition to 2,790 medical students. At the present rate of expansion, there should soon be between 14,000 and 15,000 physicians at work, whereas at present there is room for only 8,500 to 9,000. In other words, there is a real but temporary shortage, and the association's policy for dealing with it includes among other things the import of Danes, Finns, and Norwegians for whom there is no great language difficulty. Their cultural outlook also possesses many features common to that of Swedes. Negotiations have accordingly been proceeding between the various medical associations in the different Scandinavian countries with a view to the import of young physicians to Sweden. The association fears that the government's policy will dilute Sweden's medical talent to a dangerous degree and lower hard earned standards.

Tularemia.—At a meeting of the Swedish Medical Society, Dr. O. Ljung (*Nordisk medicin*, July 24, 1958) challenged the teaching that tularemia is easy to diagnose thanks to the specificity of its serologic reactions. In districts where tularemia is endemic, a high agglutination titer to Pasteurella tularensis may simply mean that infection has occurred at some time. It does not necessarily mean that the patient's present symptoms are caused by tularemia. An acute attack of tularemia may, however, be diagnosed when the titer rises rapidly in the first two to four weeks of an illness. The Widal test is apt to be puzzling, for Ljung has found that when the same material was sent to two different laboratories one reported titers four times as high as those of the other. Another speaker on the same occasion discussed the guinea pig test and the risk of infecting laboratory workers in the process. The surest road to the correct diagnosis lay in the demonstration of the germ itself (in defibrinated blood in the acute febrile stage of the disease and in the primary discharge in the ulceroglandular and oculoglandular form of the disease). In Sweden the ulceroglandular form is supposed to be more common than the other forms, but as no one knows how common the symptomless and atypical form is, this supposition may be incorrect. There is also much doubt over the relative importance of the different modes of infection. In Sweden it is probably most often conveyed by mosquitos and other insects. Elsewhere attention has been focused on contact with diseased rodents, and during World War II rats and mice in Europe were most often incriminated, being supposed to convey the disease by contaminating food and water.

UNITED KINGDOM

Mobile Physiotherapy.—A report from the Nuffield Provincial Hospitals Trust describes a scheme operating in Belfast for the rehabilitation of the elderly invalid at home. Patients are visited by a mobile physiotherapist who carries with her in a station-wagon a diathermy, shortwave, and radiant heat apparatus; ultraviolet lamps; paraffin baths; etc. Patients for home treatment are selected by a geriatrician who, in collaboration with a general practitioner, prescribes suitable physiotherapy and home care. The treatment is explained to the patients and their relatives. The cooperation of the latter is essential for home management of disabilities in the elderly. Generally speaking the results were good: 32% of the patients were much improved, 35% showed some improvement, and 33% did not respond. In addition to mobile physiotherapy and medical care, some of the patients needed home help, nursing care, laundry service, dietary supplements, and social care. All these needs cannot be met by one authority and cooperation between personnel employed by the health service, local authorities, and voluntary services is necessary. Few general practitioners have the time to coordinate all the services needed by such patients, and the report suggested that in every community there should be a coordinating center to deal with the problem of rehabilitation of the elderly, which is one of the gaps in the provisions of the National Health Service. This center should be staffed by personnel with special experience in this type of work.

Framycetin.—Trials with the French antibiotic, framycetin, produced by a species of Streptomyces decaris, were reported by Burrows (*Brit. M. J.* 2:428, 1958). Because this antibiotic is toxic when given systemically, it is used for local treatment only. Burrows used it to treat over 100 patients with such skin infections as impetigo, eczema, folliculitis, and sycosis barbae. The causative organisms, Staphylococcus pyogenes var. aureus and Streptococcus hemolyticus, were tested in vitro on blood agar for sensitivity. All strains of the former were sensitive to framycetin, but 65% of the streptococci were resistant. These were sensitive to chlortetracycline. Infections caused by staphylococci disappeared fairly rapidly. Nearly 70% of the cases of impetigo cleared within a week, indicating that framycetin is an effective antibiotic in this condition and that it compares favorably with neomycin. Only two cases of skin infection failed to respond to framycetin. No undesirable reactions or cases of sensitivity were recorded. The resistance of Str. hemolyticus to the antibiotic is, however, a serious drawback to its use in infective skin conditions.

Traffic Accidents.—An annotation in the *British Medical Journal* of Aug. 9 states that traffic accidents are becoming one of the greatest public health problems of the day. They caused 5,500 deaths and over 60,000 serious injuries in Great Britain in 1957. Unfortunately such accidents are no longer news and nobody seems to care about them. Meanwhile a certain amount of technical research goes on into the mechanical causes of accidents. Owing perhaps to the greater acceleration and smaller wheels of modern cars, skidding is reported to be increasing. It played a part in 13% of personal-injury accidents in 1954, 14% in 1955, and 15.5% in 1956. More skids due to wet roads are seen in summer than in winter. Part of this might be due to the greater impatience of some drivers on congested roads. At any rate, a careful watch is kept for dangerous sites, and the road surface is altered when found to be defective on test. A yielding rather than a rigid steering wheel shaft would reduce the severity of the injury to the driver. Toughened safety glass is safer than the laminated variety. In relation to the damage done by traffic accidents, the amount spent on research into them—about $200,000 a year—seems small, but mechanical safety is probably only a small part of the problem. The greatest menace is still the inconsiderate, inexperienced, careless, and overconfident motorist.

Dilemma of the Hospitals.—A recommendation in June that nurses' working hours should be reduced from 96 to 88 a fortnight has started a revolution in hospital wards. Nurses are shedding the extraneous duties which have accumulated round their basic role. The shorter working week has to be introduced without more money being provided for extra staff or payment of overtime. Hospitals in many areas are already short of nurses. Nurses and midwives are faced with a challenge. Only reorganization and full use of their skill and experience will bring the additional leisure time they desire. Much will depend on the attitude of managements. Already hospitals in several parts of the country have introduced the 44-hour week. The following letter appeared in the *Daily Telegraph* of Aug. 16, over the name of a hospital matron in London:

"Sir, The fortunes of the nursing profession appear to be at ebb tide. In spite of all the Government has done to improve conditions for nurses, we do not appear to be able to retain them . . . after they are trained. Many emigrate to other countries for better salaries and conditions, some leave nursing for more remunerative work elsewhere, and some marry. . . . Now . . . without being allowed any increase in our numbers of nurses, we are asked to reduce their working hours from 48 to 44 hours per week. . . . If we could attract and engage more nurses to be able to bring about this worthy reduction in working hours, there would be universal rejoicing in our hospitals. But we are forbidden to engage more, and yet we are expected to maintain a 24-hour service to our patients, without reducing our standards of nursing care. . . . Two bright ideas have occurred to the writer which are almost certain to be turned down by the powers that be, but both of which offer a solution to our desperate problem. The first is to reduce nurses' duty time to 44 hours per week and then allow them to work four hours overtime per week (at overtime rates which will have to be introduced) if they so wish. . . . The second is an even more controversial idea. Many people claim that student nurses leave the profession during training because of mental and physical overstrain. They complain that the syllabus of subjects is too full and too comprehensive. Therefore, if nurses cannot study and work without strain in a three years' course of 48 hours a week, how can they master it in a three years' course of 44 hours a week? Would it not be more sensible to reduce the hours per week, but lengthen the training from three years to three and half years or even to four years? This should lessen the strain and ensure that a well-instructed and experienced student went to her State examinations. And it would provide that greatest of all treasures to the hospitals, the fourth-year nurse who could be graded as a junior staff nurse."

Efficiency Experts to Streamline Hospitals.—The hospital service is to be streamlined over the next few years. Industrial efficiency experts are to introduce new methods. So successful has been an experimental organization and methods service that Mr. Walker-Smith, Minister of Health, has decided to put it on a permanent basis and enlarge it. Under a full-time assistant secretary it will review traditional ways of doing jobs and is expected to achieve greater economy and efficiency. While any step likely to improve efficiency would be welcome, some fear that all human feeling may be driven out of hospital treatment in the process. Running the 3,000 state hospitals accounts for 54% of the 2,000 million dollars which the National Health Service now costs annually. Hospitals have been asked to review their purchasing methods. It is hoped to extend the system under which groups of hospitals join together to buy supplies. Hospitals no longer needed to treat tuberculosis cases or sick children are being used for the mentally ill (now occupying 40% of all hospital beds), the aged sick, and others. The aim of the new building now going on is to increase still further the outpatient services and the use made of beds. The strain on the hospitals will be eased in two other ways. There will be more emphasis on disease prevention, and the liaison between hospitals, local health departments, and family physicians will be increased. The ministry aims to improve the status of the general practitioner, who is regarded as a key man. It also believes that strengthening of home nursing services will keep many more people out of hospital.

Sensationalism in Medicine.—The *British Medical Journal* of Aug. 2 reported that Dr. A. K. Bowman of the Scottish Western Regional Hospital Board feared an increase in hypochondriac tendencies and even the development of neuroses among people absorbing the wide range of television programs and press articles on medicine. Already people are going to their doctors with vague fears and anxieties about their health. The impact on their minds of watching a television program on a new treatment could convince them that they might have the symptoms of the disease. A program from the Western Infirmary, Glasgow, on the use of radioactive iodine in endocrine disorders sent several people to their doctors, self-convinced they were ill. Dr. Bowman had heard of only one case in which such a program had had a fortunate result.

The Anti-Smoking Campaign.—The National Society of Non-Smokers reports that in the first two months of its existence the smokers' clinic established in London was attended by about 150 people, of whom about 30 claim to have been cured of the habit. Many of these have established clinics in their homes. Week-end courses for a maximum of 65 tobacco addicts were started in September at $8.40 per "student." Lectures are given by chest physicians, psychotherapists, and health officers. To help those attending to comform to the "no smoking" rule, a hypnotist is in attendance.

Children in Hospital.—In a memorandum entitled "The Welfare of the Ill Child in Hospital," the child psychiatry section of the Royal Medico-Psychological Association stated that the popular notion that the younger the child the better the age for operating applies to only very young infants. Operations between the ages 1 and 5 years should be avoided if possible. It is recommended that once the child is admitted to the ward the parent should help to put him to bed and, if a bath is necessary, assist in this also, because unfamiliar baths can be particularly alarming at this stage. In this way the mother has done her part in conveying her acceptance of the situation to the child. It is recommended that, in spite of administrative difficulties, the question of children wearing their own clothes should be given careful attention. It is considered most inadvisable for children and adults to be together in the same wards, even for a short stay. This also applies to adolescents, who should have their own wards. In the English cultural setting separate wards for adolescents of each sex is advisable, without any rigorous separation when they are up and about.

It is most advisable that young children (up to the age of 4) should be with their mothers when in hospital, but it is admitted that at times the choice must be made between this and ignoring other demands at home. The hospital nurse can act as a mother substitute more effectively to the infant in arms than to the older child. To avoid further confusion in the child's mind and to prevent conflicting loyalties, the number of staff who tend him should be as small as possible (one person ideally). Changing staffs and changing shifts cause distress, which must be borne in mind. The excessively orderly hospital wards, with a few pleasantly arranged flowers, slippery floors, and neatly made beds signifying hygiene and efficiency to the medical and nursing staff, are not advocated. Immobility, when this is not essential, adds to a child's miseries and leads to bad behavior.

The Cost of Health Service.—The annual report on the National Health Service for 1957 states that the total cost of the service for England and Wales was about 1.6 billion dollars, of which about 64.4 million dollars was repaid by those using the service. The hospital service absorbed around 1 billion dollars and 176 million dollars was spent on the general practitioner service. The drug bill was 151 million dollars. The number of new patients fitted with hearing-aids during the year was 52,166, bringing the total to over 580,000 since the inauguration of the service. During the year over 4.5 million pairs of spectacles were provided. An analysis of the cost of the hospital service showed that medical salaries accounted for just under 10%, nursing salaries for just under 20%, and other wages and salaries for about 35%. Salaries and wages accounted in all for 31.2% of the gross cost, compared with 3.5% for drugs and dressings.

There were 19,343 principals and 1,465 assistants in general practice in the service. The number of principals in single practice was 6,381, and 67% of principals were in partnership. Most partnerships consisted of two physicians, and there were only 50 consisting of six or more. There were 1,331 practitioners aged 66 and over, and 616 of these were in single practices. There were 40 assistants in this age group, and 8 of them were aged 76 and over. The average number of patients per doctor was 2,273. The number of general practitioners who attended refresher courses was 1,763. An analysis of the drugs dispensed by pharmacists for general practitioners during the year shows that cough preparations headed the list, accounting for 11.3% of the prescriptions, but only 5.1% of the total cost. Antibiotics, on the other hand, headed the expense list, being responsible for 19.9% of the total cost, but only 7.2% of the total number of prescriptions. The next most expensive item was hormones other than sex hormones but including corticosteroids. These were responsible for 9.7% of the cost but only 2.5% of the number of prescriptions.

Griseofulvin.—A preliminary account of successful treatment of experimentally induced ringworm in guinea pigs by oral administration of the antibiotic griseofulvin was reported by J. C. Gentles (*Nature* 182:476, 1958). This metabolic product of several Penicillium species was markedly fungistatic to many fungi in vitro and showed systemic antifungal activity in plants. It is said to have a low toxicity for mammals. Guinea pigs were infected experimentally with Microsporum canis and treatment with griseofulvin started 10 days later when the lesions were well developed. The dosage was 60 mg. per kilogram daily by mouth. Control animals were given inert tablets. The beneficial effects of the antibiotic were evident clinically within four days of starting treatment, and the highly inflammatory reaction that developed in all the control animals was prevented. Histological examination showed that by the eighth treatment infected follicles were present only rarely, while in the control group almost all the hair follicles were heavily invaded by the fungus. In the treated animals the fungus was present in only the upper part of the hair shaft, the uninfected basal portion being sharply delimited from the invaded part. The uninfected part of the hair was apparently formed during the treatment with griseofulvin and resisted invasion by the fungus. It was also found to be effective on oral administration in guinea pigs experimentally infected with Tricophyton mentagrophytes, and it has also been used successfully for the treatment of Tricophyton verrucosum infection induced in cattle. In vitro it is active in low concentrations against all the common dermatophytes.

Epidemic of Tuberculosis.—An outbreak of pulmonary tuberculosis in a mixed day school of 650, resulting in five cases requiring sanatorium treatment and eight cases of primary tuberculosis, was reported by Dr. H. Bryant (*Med. Officer* 100:120, 1958). A 15-year-old boy in the fifth grade was sent by his family physician for mass x-ray examination and found to have pulmonary tuberculosis. Inquiries then revealed that four cases of tuberculosis in the school had been reported in the preceding 15 months. The whole of the fifth grade (104 children) were x-rayed on large films and were skin-tested. This revealed a boy and two girls in the 15 to 16 year age group with the disease. They were immediately admitted to hospital. By reason of strongly positive skin reactions, x-ray signs, or both, eight other children were thought to have primary tuberculosis. X-ray examination was also offered to the teaching and other staff, and this revealed a teacher working particularly with the upper grades who had suffered from tuberculosis, was under supervision at a chest clinic, and needed treatment. Officially her disease had been quiescent for six years, but full examination revealed a possible cavity. She was admitted to a sanatorium. By this time the school had closed for the summer.

At the beginning of the autumn term arrangements were made for the rest of the children to be skin-tested and mass x-rayed. This revealed two further cases: a boy 17 years of age and a girl who was found to have firmly calcified tubercles in her right lung. It was decided that the most probable course of events was that the infection had emanated from the member of the staff, but there was evidence of a stream of infection confined largely to the fifth grade and particularly in those grades where no less than 87% of the children had positive skin tests. One of the children may have received the infection from the original source and acted as the main source of dissemination among his classmates.

Thrombocytopenic Purpura.—A series of 93 patients with idiopathic thrombocytopenic purpura was studied by E. J. Watson-Williams and co-workers (*Lancet* 2:221, 1958). No treatment other than whole-blood transfusion or hematinics was given to 26 patients. The rest were divided in two groups, according to whether they had a history of more or less than 100 days from the onset of symptoms to the start of treatment (long-history and short-history cases). Short-history cases tended to remit spontaneously, and the onset of such a remission appeared to be hastened by steroid therapy. Splenectomy was followed by a good response in more than 75% of the short-history patients in whom a remission, spontaneous or induced, had not occurred. In long-history cases the chances of a spontaneous remission or of a lasting remission from steroid therapy appeared to be small, but splenectomy was followed by a good result in 50 to 60%.

It was therefore suggested that the initial management of the patient with a short history of purpura should be blood transfusion, to replace any serious blood loss, and administration of 75 mg. of cortisone or 15 mg. of prednisolone every six hours for three weeks. If the platelet count rises during this time, there is a good chance that it will be maintained. If there is no improvement within this period, splenectomy should be performed. The authors observed no evidence that the patient in the acute hemorrhagic phase is benefited by splenectomy. Patients with a long history of relapsing purpura should also be given a three-week course of steroid therapy. As it is exceptional for any remission obtained with such therapy to last for more than 60 days, all these patients should have a splenectomy either during the steroid-induced remission or as soon as it is apparent that the treatment has failed to influence the platelet count. On the other hand, if a remission does occur, it may be justifiable to defer operation in milder cases, especially if it is a response to a first course of steroids. In these circumstances delay is probably harmless provided the patient is kept under constant hematological supervision so that an impending remission can be anticipated and a further course of steroids given as a preliminary to splenectomy. In this series the chances of a permanent remission after splenectomy were about 50% up to 20 years after operation.

Murder by Insulin.—Last December a male nurse was found guilty of murdering his wife by injecting her with insulin. According to V. J. Birkinshaw and co-workers (*Brit. M. J.* 2:463, 1958), in an article giving the full technical details of the medicolegal investigation of the case, this is the first occasion on which such a charge has been substantiated and the first in which insulin has been demonstrated in human tissue, other than the pancreas, after death. When sent for by the husband, the police found the woman dead in her bath, which was empty of water. The husband's story was that he found her submerged in the bath and apparently drowned; he had removed the plug to let the water out and then tried artificial respiration. Postmortem examination revealed that death was caused by asphyxia due to drowning and that at the time of death the deceased was probably under the influence of a drug. Two injection marks were found on each buttock, and examination of the tissues underlying these revealed the presence of a substance that produced hypoglycemia on injection into mice and guinea pigs and stimulated glucose consumption by the isolated rat diaphragm. These biological effects were reduced or abolished by cysteine, pepsin, insulinase, the serum of insulin-sensitized guinea pigs, and anaerobic incubation. As these properties are characteristic of insulin, and no other known hypoglycemic agent could have produced the same combination of effects, it was concluded the active material in the tissue extracts could only have been insulin.

The amount of insulin isolated from the tissues was 84 units in 170 Gm. of tissue. The distribution of the insulin was uneven, there being more in the left buttock, which was the site of the most recent injection mark, than in the right, and more in the superficial than in the deep tissues. The large amount found and the uneven distribution indicated that its presence was not the result of endogenous secretion. It was estimated that at the time of death the buttock tissues contained at least 240 units of insulin—sufficient to produce either the soporific or comatose stages of the hypoglycemic state. The husband explained the injection marks by saying that his wife was pregnant and he had given her injections of ergonovine in an attempt to produce an abortion. No evidence of ergonovine could be found in the body.

Penicillin Sensitivity.—Penicillin cream has been used as the routine treatment of burns at the Birmingham Accident Hospital since 1945, on the grounds that it is the best prophylactic agent against colonization with Streptococcus pyogenes, which so often causes graft failure. In view of the reported increasing incidence of sensitivity reactions to penicillin, it was decided to investigate the matter. Mary R. Davies reported (*Lancet* 2:345, 1958) the findings in a series of 1,419 burned patients. Of the 1,232 who received local penicillin cream, only 6 (0.5%) had a reaction possibly attributable to penicillin, compared with 4 of 54 (7.4%) receiving injections of penicillin. Most of the reactions were mild, and none lasted longer than four days. The sensitivity state may be transient. Six of the 10 patients with sensitivity to penicillin in this investigation had no reaction to subsequent local application of the antibiotic. In view of these findings it was concluded that penicillin cream can justifiably be applied prophylactically.

CORRESPONDENCE

PLEA FOR IMPROVED TRAINING IN SYPHILIS

To the Editor:—For many years syphilis has been accepted as a public health responsibility, and its management, to a greater extent than that of most diseases, has been concentrated in clinics supported entirely or partially by public health funds. This can be explained by the fact that a large number of patients are in the lower socioeconomic groups and by the fact that the epidemiology of infectious syphilis not only is a public health responsibility but also is best conducted by public health personnel. Under these circumstances it is inevitable that control of the disease depends largely on the adequacy of public health programs. However, no program of disease control can be successful without the cooperation of the entire medical profession. The diagnosis and treatment of syphilis have never been confined to clinics; like other diseases syphilis has always been a responsibility of general medicine.

Within recent years many syphilis clinics have been closed, with the result that tax-supported services depend increasingly on private physicians for the management of syphilitic patients. Many state health departments now provide fees to private physicians for this purpose. Regardless of whether fees are paid by the patients or by other agencies, it is obvious that syphilis cannot be controlled without maximum cooperation between public health services, hospitals, and private physicians.

Unfortunately, syphilis has been peculiarly neglected by the medical profession in general since the early years of this century. The venereal stigma may be partially responsible, but the chief explanation seems to be that management of the disease has been largely in the hands of specialists. The advent of rapid treatment and the recent marked decline in the number of cases now prohibits further concentrated specialization in syphilis, with the result that general practitioners must accept responsibilities that were previously left to specialists. Lack of interest in syphilis by the medical profession in general is difficult to understand from a scientific point of view, because the disease continues to present numerous unsolved problems.

Among the infectious diseases syphilis probably ranks first in the complexity of its manifestations and of its immunological mechanisms. It has numerous features that seem to be unique in human infections. Osler's epigram, "to know syphilis is to know medicine," might be worded more exactly, "to understand syphilis is to understand immunology." The gaps in our knowledge of immune mechanisms are shown more clearly in the study of syphilis than any other single disease. Syphilis still presents a fascinating challenge to scientific medicine. But, in spite of unanswered questions, the disease can now be diagnosed with reasonable accuracy, and its treatment is relatively simple. Nevertheless, outside of special clinics, the management of syphilis frequently is characterized by inexcusable confusion and by errors of omission and commission.

Errors of omission include the following:

1. Failure to obtain serologic tests for syphilis (STS) from patients who are likely to have been exposed to the infection or who have signs and symptoms suggestive of the infection. A possible diagnosis of syphilis should be considered in every patient with a genital lesion or with skin and mucous membrane lesions suggestive of syphilis. There need not be primary or secondary syphilis before laboratory tests are done. Syphilis should be considered when patients have early infectious lesions; yet in numerous patients with such lesions the condition has been undiagnosed for weeks because the physician did not think of syphilis.

2. Often patients with positive STS recorded on their hospital charts are discharged from hospitals without anyone paying attention to the positive test. This applies to patients who enter the hospital because of some disease other than syphilis.

3. Too frequently, no history of previous STS or previous treatment for syphilis is obtained in patients who are diagnosed as having syphilis. It is difficult to obtain accurate histories of syphilis from many patients, but useful information can usually be obtained by careful questioning. Without history of previous STS and previous treatment the physician often is working in the dark in managing seropositive patients.

4. Frequently there is failure to report cases that are diagnosed and treated.

Errors of commission include (1) repeated treatment of patients solely because of the persistence of positive STS, (2) excessive total doses of penicillin and an unnecessary number of injections because of relatively small individual doses, (3) repeated courses of treatment given in a vain effort to reverse late signs and symptoms of syphilis that are irreversible, (4) incorrect diagnoses of "early" and "late" cases because no attempt was made to obtain adequate histories that were actually available, and (5) in a patient with a positive STS, syphilis is accepted as the cause of signs and symptoms that are due to something else.

In a complex disease such as syphilis it is inevitable that mistakes will be made and that there will be differences of opinion about difficult diagnoses. No one is infallible, but the above-mentioned mistakes are so common in hospitals and in physicians' offices as to warrant attention and remedy by organized medicine.

Since the advent of penicillin, many articles on the management of syphilis have been written by physicians working with the disease. Carefully conducted studies inaugurated originally by a committee of the National Research Council and subsequently sponsored by the U. S. Public Health Service have been reported. The studies were conducted by a number of cooperating hospitals and clinics. They have provided data that are certainly as authoritative as any that are now available, and they have resulted in complete agreement by the physicians in charge on certain fundamental principles of diagnosis and treatment.

Differences over theories, unusual cases, and exact dosages for the various types of syphilis are to be expected. Dosage schedules for any disease must be flexible. Public health departments usually advise minimal schedules of penicillin therapy based on their effectiveness in extensive trials. State departments of health differ somewhat in their advised schedules, but none advises total dosages as great as 10 million units of penicillin for asymptomatic syphilis or repeated treatments because of persistent positive STS in patients treated for late syphilis. Yet it is not unusual to find asymptomatic persons with syphilis being treated with more than 10 million units of penicillin by private physicians and in some hospitals. It has been well known for at least the past 25 years that it is futile to re-treat patients with late syphilis solely in the hope of reversing positive STS to negative. Yet many physicians seem to be unaware of this fact, or they ignore it.

The dearth of suitable material for teaching purposes in medical schools has resulted in little or no instruction about syphilis to many medical students. Hospital interns well trained in medicine often have no hesitancy in declaring their ignorance of syphilis. It is no longer feasible to attempt to teach syphilis in medical schools through examination of patients; but should not all medical schools provide a few hours of didactic instruction to students based on the modern concepts of the management of syphilis as accepted by public health services in this country and by the World Health Organization? Such instruction cannot cover all of the manifestations of the disease or devote time to its numerous intricacies. However, it could provide reasonably uniform information about the importance of histories in syphilis, the interpretation of serologic tests, and general principles of treatment.

There is no reason why syphilis should be relegated to a hinterland of medicine. The disease is still relatively common in the lower socioeconomic groups. In 1957 in New York state alone, 106 individuals were admitted to New York state mental hospitals because of general paresis. Most of them will remain in the hospitals for the rest of their lives. Modern antisyphilitic therapy can check the progress of general paresis and prolong the lives of paretics, but it cannot restore function to permanently damaged brains. Crippling neurosyphilis and cardiovascular syphilis can be prevented by treatment during the many years after infection that usually intervene before serious damage has occurred.

In 1956, Malzberg, of the New York State Mental Hygiene Department, reported that in 1950 there were more paretics receiving custodial care in New York state hospitals than in 1920, yet the rate per 100,000 population of admissions to state hospitals because of general paresis in 1920 was 7.9 compared to 2.8 in 1950 and 0.7 in 1957 (Malzberg, *Ment. Hyg.* 40:583-596 [Oct.] 1956). This paradoxical finding is explained in part by the fact that paretics now live longer and so remain in the hospitals for many more years. The fact that there are now almost 3,000 patients in New York state hospitals because of general paresis should alone awaken the medical profession to its responsibilities in syphilis control. If syphilis is to be controlled, a new interest must be established within the medical profession, and the place to begin would seem to be the medical schools.

PRECIPITATION TEST AND SYSTEMIC LUPUS ERYTHEMATOSUS

To the Editor:—An article entitled "Evaluation of Simple Precipitation Test for Systemic Lupus Erythematosus" by Jones and Thompson appeared in The Journal, March 22, 1958, page 1424. Since that time, we have had the opportunity to perform this test in the lupus erythematosus laboratory at the Los Angeles County General Hospital 313 times in 258 patients with various disorders. The results of this test have been correlated with results obtained from the rotary method (Dubois and Freeman, *Blood* 12:657-670 [July] 1957). The precipitation reaction in our experience is completely nonspecific for systemic lupus erythematosus.

These findings are similar to those of Lee and Schultz published in the Correspondence section of The Journal, July 19, 1958, page 1552. In view of the extensive use being made of this test throughout the United States; we thought that it would be of value to publish our results as well, so that this test would not be used as a screening procedure for systemic lupus erythematosus. The table outlines the results in various disorders. The precipitation test was performed simultaneously on serum and plasma from the same blood samples on which the L. E. cell tests were performed. In general, plasma gave a slightly higher titer of the precipitation reaction than did serum. The method of Jones and Thompson was followed in detail, and the degree of positivity was checked on a sample sent us by Dr. Jones so that our interpretations of the test reactions are comparable to his.

The most important groups to observe in the table are the untreated patients with active systemic lupus both with and without L. E. cells. Note that in 27 such patients who had 37 tests, 22 of the tests were completely negative, in contrast to 100% positive results in Jones' 13 similar cases. The reaction, it is true, as emphasized by the originators of it, does tend to become negative with spontaneous or therapy-induced remissions. The other important point to note from the table is that the incidence of positive results in patients with classic rheumatoid arthritis with negative L. E. cell tests was as great as in the patients with typical systemic lupus erythematosus. All the other positive results are listed in the table, including the large number in patients with Laennec's cirrhosis.

Results of 313 Precipitation Tests for Systemic Lupus Erythematosus Correlated with L. E. Cell Factor and Status of Patient

	Cases, No.	3+	2+	1+	Negative
Systemic lupus erythematosus, treated*					
L. E. cells present	30	1	7	4	28
L. E. cells absent	21	1	4	5	23
Untreated in remission					
L. E. cells present	8	1	1	1	7
L. E. cells absent	11	...	2	1	12
Untreated disease, active					
L. E. cells present	18	2	6	2	13
L. E. cells absent	9	1	1	2	9
Discoid lupus erythematosus					
With systemic manifestations	5	...	...	1	8
Without systemic manifestations	14	2	1	2	13
Rheumatoid arthritis (L. E. cell test negative)	53	3	13	5	37
Laennec's cirrhosis	11	1	6	2	5
Scleroderma	3	...	...	1	3
Dermatomyositis	2	...	...	...	2
Glomerulonephritis (acute and chronic)	7	...	1	...	6
Thyrotoxicosis	2	...	2	...	1
Congestive heart failure	1	...	2	...	...
Tuberculosis, active	1	...	1	...	1
Miscellaneous diseases	31	...	...	...	35
Normal	18	...	...	...	25

* Either steroids and/or antimalarials.

An attempt was made to determine whether this precipitation test correlated with any of the other routine laboratory tests. One hundred sixty patients had total protein and albumin globulin ratios determined by the salt fractionation method (Howe or Wolfson), and cephalin cholesterol flocculation and thymol turbidity tests were also done. These were performed within a week of the precipitation (p-toluene-sulfuric acid) and L. E. cell preparation tests. The only correlation found was that whenever a positive precipitation test was present (1+ or more), hyperglobulinemia was almost invariably present. The precipitation test was always negative if the total globulin levels were normal. Unfortunately in half the cases of hyperglobulinemia, the precipitation test was negative, so it had no value as a screening test for hyperglobulinemic states. There was no correlation between cephalin cholesterol flocculation or thymol turbidity and this test. Total cholesterol level determinations in 26 patients did not correlate with the precipitation reaction. It is our impression that the test is completely nonspecific. It is of value only when positive, and then it indicates the presence of hyperglobulinemia. As a diagnostic procedure for systemic lupus erythematosus, it should be abandoned.

MISUSE OF DRUGS

To the Editor:—Recent information reveals that a potentially serious situation may be developing in regard to the proper use of the two formulations of the new antibiotic kanamycin (Kantrex) which is currently available on the U. S. market.

To clarify the differences two points should be emphasized: 1. Kantrex Intramuscular is the only dosage form available for the treatment of systemic infections caused by kanamycin-sensitive micro-organisms. 2. Kantrex capsules are indicated solely for preoperative intestinal antisepsis and for the treatment of local infections caused by kanamycin-sensitive micro-organisms—and not for systemic use, since the formulation for oral use is not absorbed from the gastrointestinal tract.

Although the above information has been the subject of a recent letter sent to 145,000 practicing physicians in the United States, it seems desirable to bring the problem to the attention of the readers of THE JOURNAL. By this means it should be possible to identify the precise use of the new antibiotic to the medical profession of this country and thereby prevent the improper use of Kantrex capsules in the treatment of patients critically ill with systemic infections.

THE LEISURE CORNER

PLAYING THE MODERN ORGAN

Many new channels have opened up in the field of music in recent years. The modern organ now meets demands never before associated with this instrument. Its range and repertoire have been considerably broadened, and its versatility is so extensive that it startles those persons who have never had any formal musical training. Many physicians would like to play a musical instrument; many go through life without learning to play; others start when they are very young. An increasing number of physicians, however, turn to music in their mature years, many selecting the organ because it is a practical instrument for home use, it is easy to play, and it gives complete relaxation.

Probably the earliest form of the organ (in use in 500 B. C.) was an instrument the Greeks called the Pipes of Pan. This instrument consisted of hollow tubes of different lengths, and the player blew into or across the open upper-ends of the pipes. About three centuries later, Ctesibius of Alexandria constructed an instrument in which air was forced into the pipes by means of water power. Byzantium was the first city to become an important center for building organs. It was here that the pneumatic organ, with wind furnished by bellows, was first used. Along about 600 A. D., during the time of Pope Vitalian I, the church organ came into use. Then, between the 14th and 19th centuries, the Germans took a keen interest in the building of organs. In the United States, the first American organ played by electrical power was introduced at the Centennial Exposition in Philadelphia in 1876.

The reed organ, better known as the harmonium or melodeon, was a common instrument in the churches and homes of the country districts during the latter part of the last century. The tones, ranging from low to high were made by one or more series of different-sized reeds, similar to those found in the accordion or the harmonica. The keys opened valves to let air into the reeds. The pressure of the air was maintained by pumping up and down on two pedals. Present-day harmoniums are blown with a suction blower similar to that found in a larger pipe organ.

In general, the pipe organ is the largest and most powerful of all musical instruments. Any type of music can be played and most orchestral tones may be simulated. Instrumental tones such as those belonging to the violin, cello, double bass, clarinet, trumpet, oboe, bassoon, English horn, and saxophone may be duplicated, not to mention those which belong to the organ alone. The modern organ is probably the easiest of all instruments to play. One does not have to practice for long hours, and in a matter of minutes you find yourself playing simple tunes. The reason for this is that the instrument maintains sustained tone; press a key, and the tone remains until you release it. One-finger tunes sound surprisingly attractive for this reason, and it allows for delay between notes. Moreover, it permits a beginner to search for the next note without incurring a feeling of self-consciousness.

Any type of music you like may be played, including classical, jazz, folk tunes, church music, waltzes, fox-trots, rumbas, and the like. It is possible to simulate the score of a musical instrument if a song sounds best on any particular instrument. All of the string, woodwind, and bass instrument tones are right at your finger tips, to be employed individually, together, or in full orchestra. In addition to the basic instruments, one can blend thousands of fascinating tones, and it is this type of "flavoring" that results in much pleasure in playing the modern organ.

Modern organs are light in weight and can be moved readily from one room to another. All one has to do is unplug the console and tone equipment. There is very little maintenance cost after several years. Even the amount of electrical current used is extremely low. The modern organ uses electric amplification to increase the volume of sound and has three factors in common with the pipe organ: 1. The tone may be sustained or held for as long a time as wanted. 2. The sound may also be increased or decreased while being sustained. 3. The same kind of range of tone-volume from soft to loud is found in both instruments. These three factors make the electronic organ sound like the pipe organ, and many electronic organs are used in their stead. A primary difference, however, is that the electronic organ tone, always heard through loud speakers, makes good ensemble or group effects.

Electronic instruments utilize radio tubes to make the sound impulses louder. These impulses are put in motion by pressing down a key on the keyboard. In one type, an electric magnet is employed to catch the various speeds of impulses or vibrations which establish the different musical tones. A second type amplifies sound of the harmonium. Tone screws are placed above each reed, and these screws pick up the musical tones derived from the vibrating reed tongue. Still another type of electronic instrument amplifies sound by putting a small microphone inside the box of reeds.

Finally, a brief comment about the structure of an organ. Its main parts consist of a keyboard, valve mechanism, pipe assembly, and a blower. When the player presses the keys an electrical impulse is conveyed to the valve mechanism which alters it into a pneumatic impulse, one made by air, and lets air into the pipes; the sound is then produced. The keyboard is set in a case called the console. Ordinarily there are several rows of keys, sometimes as many as six. These are known as manuals, for they are played with the hands. A six-manual organ is divided into the great organ, the swell organ, the choir organ, the solo organ, the bombarde, and the echo organ. In addition, there is a pedal organ consisting of large wooden keys at the base of the console. These are played with the feet. The different sets of pipes are controlled by stop-knobs at the keyboard or stop-keys above the keyboards. Pipes vary from 0.5 in. to 32 ft. in length. Organs vary greatly in size, with the smallest having about 370 pipes and the largest more than 40,000 pipes. The bigger the organ the larger the range of musical effects which it can play. Some organs are played with rolls, much like those of a player piano.

BOOK REVIEWS

Cerebral Palsy in Childhood: The Aetiology and Clinical Assessment with Particular Reference to the Findings in Bristol. By Grace E. Woods, M.D., D.P.H., D.C.H. With foreword by Peter Henderson, M.D., D.P.H. Cloth. $6.50. Pp. 158, with 42 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44 Triangle West, Bristol 8, England, 1957.

Most recent books on cerebral palsy have been mere reviews of the literature and therefore of relatively little scientific value. It is refreshing to find this publication based on clinical observations and presented in a factual manner. It is an elaboration of a doctorate thesis and is based on a study of 301 children with cerebral palsy. It presents the various types of cerebral palsy according to their clinical characteristics and attempts to correlate these with certain etiological factors. Although the case material is not large and the method of investigation is retrospective, the study is, nevertheless, critical and attempts to derive conclusions from the facts presented rather than to jam the facts into the framework of a preconceived notion. The material is presented logically. The author finds a high correlation between (1) spastic paraplegia and prematurity, (2) spastic hemiplegia and difficult or forceps delivery, and preeclampsia, and (3) athetosis and jaundice. He does not discuss treatment but limits himself entirely to etiological factors and symptoms. The literature is well reviewed, although misquoted in several areas. The book is well documented with case reports and excellent photographs showing the various clinical syndromes. The statistics are of questionable validity, but this does not detract from the clinical implications. This is one of the best monographs yet written on the correlation between etiology and clinical syndromes in cerebral palsy.

Endocrine Pathology of the Ovary. By John McLean Morris, M.D., Associate Professor of Gynecology, Yale University School of Medicine, New Haven, Conn., and Robert E. Scully, M.D., Clinical Associate in Pathology, Harvard Medical School, Boston. Cloth. $8.50. Pp. 151, with 75 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

The authors have produced a valuable contribution to the knowledge of ovarian pathology and gynecologic endocrinology. Such a book must of necessity be written by two trained observers thoroughly familiar with pathology and clinical gynecology. Only by such a team approach to the complex problem of presenting to other medical men the basic significance of the ovarian abnormalities here presented can a clear concept of what is known and what is still to be discovered be obtained. The material is clearly presented and begins with a review of the histology of the ovary from the fetus through the period of sexual maturity, including cell rests of adrenal cortex and male elements composed of Sertoli and Leydig cells found in the ovarian hilus. The embryology of the gonads and its significance in understanding various types of tumor formation is stressed together with hormone production and sexual differentiation, normal and hermaphroditic.

Hormone assays are discussed, and their value and limitations are frankly stated. A brief description of the techniques used is included. Estrinism, defeminization, masculinization, and hyperadrenocorticism are described. Neoplastic and non-neoplastic abnormalities of the ovary are adequately covered. A classification of functioning ovarian tumors which seems both clear and logical is presented. The format of the book is simple, the type is clear and readable, and numerous valuable photomicrographs make this a valuable reference work for the student, pathologist, and clinician wishing to compare these with slides from tumors not yet diagnosed. An extensive bibliography of the world

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

literature adds greatly to the value of this book for reference. A colored plate depicting the gross appearance in cut section of the more important tumors, as seen at operation, would be valuable to the surgeon in some cases in deciding the proper surgical procedure.

Forensic Medicine. By Keith Simpson, M.D., Reader in Forensic Medicine, University of London at Guy's Hospital, London. [Third edition.] Cloth. $7. Pp. 352, with 138 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Edward Arnold (Publishers) Ltd., 41-43 Maddox St., London, W. 1, England, 1958.

Although the laws quoted in this excellent book are those of England, Wales, and Scotland, the scientific procedures and reasonable inference to be drawn from such procedures are universal in application. The book was written for the practicing physician and for those beginning in the field of forensic medicine, but those adept in the subject can glean much from the author's wide experience, which is sharply reflected in the pages. The book is divided into two major divisions: forensic medicine and toxicology. In neither section are minute details for carrying out specific actions or tests delineated, although here and there one finds rather simple ones, such as laboratory tests for seminal fluid, outlined. In general, the author suggests that if one does not know what to do he should do nothing and contact someone who does know the proper handling of the material at hand. The book is adequate to enable a physician who has had no special training in forensic work to obtain knowledge so that he may assist the coroner or medical examiner. It is not the purpose of the book to make a well-rounded expert of the reader. Vignettes from the author's experience are generously used to illustrate particular points. The section on toxicology is not analytical, since few tests are given. Unfortunately, the weights and measures referred to in this section are not in the metric system. The type is clear, and the illustrations, with few exceptions, are excellent.

Essentials of Chemical Pathology. By D. N. Baron, M.D., Reader in Chemical Pathology, Royal Free Hospital School of Medicine, London. Cloth. 25 shillings. Pp. 247, with 28 illustrations. English Universities Press, Ltd., 102 Newgate St., London, E. C. 1, England, 1957.

The scope of this small volume is limited to the essentials of chemical pathology (clinical biochemistry to the American reader). This book was derived from a series of lectures given by the author, and its style is readable in a way not ordinarily found in textbooks and references. The discussion of each biochemical system is primarily directed at the normal chemistry of the system and then to the departures from normal that constitute pathological conditions. Quite properly for a book of limited scope, the more common abnormalities receive the most attention with only a brief reference to the rare though perhaps more interesting conditions. This book is not concerned with laboratory procedures, although the more common tests are outlined in an appendix. The only details given are those that involve the patient or physician directly (i. e., diet or fasting, sampling times, and interpretation of results). The details of the laboratory tests are not included. The author's objective is to bridge the gap between academic biochemistry and application of chemical laboratory data to clinical problems. It is primarily a textbook and should be of greatest value to the student for a review. Although it does not pretend to be comprehensive, it should prove useful to the practicing physician as a short reference volume, since it contains a great deal of information concisely stated and made easily accessible through a thorough index. The most serious weakness is the omission of any discussion of hemoglobin and iron metabolism.

Lehrbuch der Gynäkologie. Von Prof. Dr. med. Heinrich Martius. Unter Mitwirkung von Käthe Droysen. Fifth edition. Cloth. 49.80 marks; $11.85. Pp. 426, with 456 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1958.

Since the last three editions of this book have appeared at intervals of about two years, there have not been many changes in them. The table of contents of this new edition is identical with that of the fourth. The book is 12 pages longer and contains eight more illustrations. Since there has been significant progress in endocrinology in the past two years, the data on this subject have been brought up to date. Otherwise, the present and fourth editions are almost identical. This is by no means a fault, because all the editions of this book have been excellent. Without doubt this edition will be as popular in German-speaking countries as its predecessors, because Martius is still the outstanding author of German textbooks of obstetrics and gynecology.

Modern Treatment Yearbook 1958: A Yearbook of Diagnosis and Treatment for the General Practitioner. Edited by Sir Cecil Wakeley, Bt., K.B.E., C.B. Cloth. $6. Pp. 312, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Published for Medical Press by Baillière, Tindall & Cox, Ltd., 7 & 8 Henrietta St., Covent Garden, London, W. C. 2, England, 1958.

This English compilation contains a series of articles covering practical aspects of diagnosis and treatment of common diseases encountered in medicine, surgery, and obstetrics. The photographs are collected in a separate section in the middle of the volume, making reference to them somewhat cumbersome. The topics discussed are well chosen and range from complications of head injuries to renal aspects of diabetes. The discussions are concise and adequate. The purpose of the book is to bring the general practitioner up to date on therapeutic procedures of common disorders. This purpose has been admirably fulfilled.

BUSINESS PRACTICE

The American Medical Association, in cooperation with the Sears-Roebuck Foundation, has published a brochure on the Business Side of Medical Practice. This brochure will be published serially, excluding the illustrations, some of the sample forms, and the artwork, in the Business Practice section of The Journal, *in the interest of its readers.*—Ed.

SETTING UP PRACTICE

To most young physicians, setting up medical practice is the long-awaited climax to years of study and work. The long, laborious preparatory period is over; the medical degree is won. "Now," the young doctor tells himself, "all I have to do is hang out my shingle and begin practicing medicine."

He learns quickly that it is not always as simple as that. He discovers that he must make many important decisions—decisions affecting his entire life and his success in the medical world.

Within a relatively short interval, he must decide where to practice, determine the type of practice he wishes to develop, and solve the practical problems of establishing it. He must finance his practice, purchase equipment and supplies, find a home for his family, and establish the proper relationships with the official body granting him a license to practice and with hospitals and medical organizations.

He finds he must attend to dozens of details and make countless decisions. Suddenly the man of science must deal competently with real estate people, bankers, lawyers, salesmen, suppliers, and sometimes with painters, plumbers, electricians, and a host of other service people. For the first time, the physician comes up against the realization that if he wants to practice medicine, he must also be a businessman.

Reversing the Scientific Focus

The long years of medical training prepare the physician for meeting medical problems he encounters in caring for his patients but rarely equip him for handling the practical problems of setting up and conducting his practice. He gets little business training, yet the changing aspects of medical practice today call for an understanding of basic business principles and techniques. A generation or two ago setting up practice was simple. It involved only the purchase of a few surgical instruments and a few pieces of office furniture and the outfitting of a little black bag. Today the equipment and diagnostic aids required in the modern medical office require a big financial outlay. Today's doctor could hardly pay his office rent on what was considered a good monthly income 25 years ago.

Striking the Proper Balance

Ideally, a physician strives to seek the proper balance between the scientific and business aspects of medicine. The practice of medicine must never become a business, but there is a business side of medicine. The wise doctor realizes that, in establishing his practice on a sound foundation businesswise, he actually is setting up a self-operating pattern which in the long run gives him more time to devote to the practice of medicine.

The application of good management principles to the medical office is important to both the physician and his patients. The doctor who ignores rudimentary business principles soon finds himself short of cash and beleagured by the income tax people. Furthermore, his patients today no longer are as indulgent about haphazard record-keeping, erratic billing, and the errors that creep into inefficient systems. It's only human nature for a patient to wonder if a physician who can't keep his own office affairs in order is competent to make decisions regarding his life and health.

Good management makes sense—for it means the doctor controls his practice, he doesn't let the practice run him! The dictionary calls management "the *judicious use of a means to accomplish an end,*" and, in the medical office, that end is giving more and better service to patients. Practice management calls for the application of the scientific approach so well known to the physician. It means that in solving the problems of setting up and carrying on his practice the doctor considers all possibilities and makes the best decision in light of all circumstances. The result: a well-built practice which will run smoothly and with a minimum of attention to business detail later.

This how-to-do-it manual, encompassing the views of a number of experts on medical practice management, is designed to help a physician build and conduct a successful practice. It is not a complete answer book but a guide to some of the possible solutions to a physician's practice problems. It is written to help a physician make his own decisions more intelligently and to put him on the track of other sources of information he may require.

Ironically, the lack of management know-how among established physicians led to development of this publication. It is the outgrowth of a need which became apparent when the A. M. A. and the Sears-Roebuck Foundation prepared a medical facility planning guide for physicians in 1955. Its aim is to help physicians build practices successfully and rapidly, with a minimum of costly mistakes.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Nonspecific Granulomatous Disease of the Stomach: A Clinical Pathological Study. M. B. Goldgraber, J. B. Kirsner and H. F. Raskin. A. M. A. Arch. Int. Med. 102:10-24 (July) 1958 [Chicago].

Chronic granulomatous inflammation is a process initiated usually by a group of harmful agents which bring into defensive activity a specialized cellular mechanism—the reticuloendothelial system. The basic lesion contains at the periphery concentric reticular fibers, while the center is occupied by epithelioid cells, with or without giant cells. Granulomatous inflammation has been found in a variety of apparently unrelated conditions, including infections, Hodgkin's disease, sarcoidosis, malignant tumors, reactions to minerals and lipids, and the hyperergic state. The authors record 4 cases of granulomatous disease of the stomach. One of them is classified as part of regional enteritis; another, as part of the eosinophilic granuloma syndrome; the 2 remaining cases are of an undertermined nature. The histopathological features encountered, namely, tissue eosinophilia and granuloma formation, seem to suggest an allergic state in both cases. In cytological studies giant cells were recovered from gastric washings in 3 of the 4 patients. Cytological studies appear helpful in the diagnosis of granulomatous disease of the stomach.

Arthritis Associated with Ulcerative Colitis: A Clinical and Pathological Study. E. G. L. Bywaters and B. M. Ansell. Ann. Rheumat. Dis. 17:169-183 (June) 1958 [London].

The authors feel that the arthritis associated with ulcerative colitis has not been fully delineated, possibly because it is generally thought to be merely rheumatoid arthritis occurring in ulcerative colitis, rather than a special entity as suggested by Hench and others in 1935 and later. The authors review this problem on the basis of observations on 37 patients who had both arthritis and colitis and 30 of whom were seen personally. In the majority the colitis was of mild to moderate severity. The arthritis tended to be a recurrent mild and often migratory synovitis, localizing in 1 or 2 of the joints longest affected and frequently remitting. Only rarely did a severe generalized form of arthritis occur. Nodule formation with a persistently positive differential agglutination test was seen in only 2 patients. Roentgenographic changes did not differ from those seen in rheumatoid arthritis, although healing tended to occur more frequently and there was a moderately high incidence of sacroiliac involvement. In view of the nature of the arthritis, together with the negative differential agglutination test usually found, it is concluded that a separate form of arthritis is associated with ulcerative colitis. It is similar to that occurring acutely in erythema nodosum due to other causes, but it may last longer and may recur; in such cases chronic residual changes closely resembling those of rheumatoid arthritis may be seen.

Renal Function in Patients Recuperated from Severe Hypertension with Treatment. A. Caeiro, G. Palmieri and C. Fierro. Rev. Asoc. méd. argent. 72:45-51 (Feb.) 1958 (In Spanish) [Buenos Aires].

Eighteen patients with severe hypertension of varied etiology were observed. These patients were invalids because of cerebral and cardiac lesions. One patient had grave cardiac insufficiency, 5 patients had severe essential hypertension, 7 had malignant hypertension, 2 had pyelonephritis, and 3 had chronic nephritis; in addition, 1 patient had Cushing's syndrome. So far as renal function was concerned, 1 patient had grave renal insufficiency with uremia; 17 patients either did not have renal insufficiency or the insufficiency had been compensated. The renal function was studied in all the patients during the period of hospitalization and during the ambulant period of about 17 months after discharge from the hospital. In carrying out the treatment, the patients were placed on a diet for those with hypertension; 15 were given hypotensive drugs, 1 had a sympathectomy performed, and 2 were subjected to either a sympathectomy or an adrenalectomy in association with hypotensive drugs. All the patients showed a marked clinical improvement and were able to return to active life. In each case the eye fundus improved; the exudates, hemorrhages, and edema of the papilla disappeared. The size of the cardiac area remained unchanged, and the renal function did not change.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

According to blood pressure readings, the systolic pressure was lowered from 201 to 149 mm. Hg and the diastolic pressure from 124 to 91 mm. Hg. The 2 patients with pyelonephritis died several months after having had a marked improvement in the malignant symptoms of hypertension. One patient died of a cerebrovascular hemorrhage and another of renal insufficiency. The results of this study show that the actual treatment of severe hypertension by means of diet and either hypotensive drugs or hypotensive operations or both causes reversibility in the symptoms of invalidism and in the malignant phase of the disease. The treatment is symptomatic. It does not modify the natural course of the disease.

Haemophilia-Like States in Girls. A. J. Quick and C. V. Hussey. Lancet 1:1294-1298 (June 21) 1958 [London].

The authors had available for repeated studies 4 girls with a bleeding condition resembling hemophilia. The first patient was noted to bruise easily in early infancy, but her first serious bleeding occurred at the age of 18 months when she cut the frenum of her upper lip. At 3 years she had a large hematoma on the medial aspect of her left thigh and a swollen knee. She required several transfusions. Hemophilia was diagnosed on the basis of the normal prothrombin time and a prolonged clotting time. These findings were confirmed when, in addition, a very poor consumption of prothrombin was found. No correction was observed when the patient's blood was mixed with that of a known hemophiliac. Physical examination was normal except for old ecchymotic spots, a hematoma on her right elbow, and swelling of the sole of her right foot. When she was last seen at the age of 10 years her blood was studied, and the same tests were run simultaneously on the blood of a patient known to have severe hemophilia. No deformity, enlargement, or limitation of movement of any joint was found, but when the right knee was flexed, a sharp click was constantly heard. True hemarthrosis was not shown on roentgenography. Most of the severe bleeding was intramuscular. The bleeding disorder in this child is indistinguishable from classical hemophilia, except that the family history is negative. For this reason, the cause of her condition is best explained by mutation, but this is speculation, and proof can only be established by her offspring. All her sons should be bleeders and all her daughters carriers, if this assumption is correct.

The second patient, in addition to defective consumption of prothrombin and defective generation of thromboplastin, had a prolonged prothrombin time. Her disease was similar to, or probably identical with, the entity recently named "Stuart clotting defect." The third and fourth patients had a normal prothrombin time but a very prolonged bleeding time, defective consumption of prothrombin, and faulty generation of thromboplastin. The suggested name "pseudohemophilia B" has been tentatively accepted to designate this disease. A bleeding disorder in a girl is especially serious, because little is known about the hemostatic control of menstrual bleeding. Nearly all the women with a hemophilia-like condition have been more than 20 years old when they were first studied, suggesting that their bleeding was relatively mild. Some of these patients have normal menstruation.

The Clinical and Histologic Spectrum of Pyelonephritis. G. E. Schreiner. A. M. A. Arch. Int. Med. 102:32-40 (July) 1958 [Chicago].

Surveys have shown that less than 1 in 5 cases of pyelonephritis is diagnosed before death. This situation obtains not only because of the prolonged and insidious nature of the disease but also because of its protean clinical manifestations. Pyelonephritis is one of the great imitators. The present study presents a brief classification of pyelonephritis, a review of known etiological and bacteriological factors, a description of the histological spectrum of the lesion produced in the kidney (which has been gathered largely from living patients by means of renal biopsy), and a survey of the clinical spectrum of pyelonephritis. The author decries the use of vague or erroneous terms, pointing out that pyelitis, if used correctly, should be limited to an inflammatory process confined to the epithelium of the renal pelvis. Pathological studies have shown that this lesion must be an exceedingly transient one. Focal inflammatory reaction in the renal parenchyma is present almost invariably when the epithelium of the renal pelvis has been invaded by bacteria. This term has done harm; by its implication of a superficial infection, it promotes a sense of security which is unwarranted in the initial phase of pyelonephritis.

In a simple classification pyelonephritis is divided, first, into 3 stages: acute, chronic, and healed. Secondly, it is classified as to its effect on the kidneys as atrophic or nonatrophic, depending on whether the size of one or both kidneys has been altered with the scarring process. Third, the disease may be unilateral or bilateral, a fact not always easy to ascertain. Fourthly, pyelonephritis is classified as primary if no known etiological condition is present to explain its genesis or secondary if it occurs after one of the known causes of pyelonephritis.

With increasing use of antibiotics, pyelonephritis in many hospitals has approached respiratory disease as the most important infectious disease, and recently in several hospitals it has exceeded the incidence of respiratory infection. Scars of pyelonephritis have been reported in as high as 20% of the hospital population randomly sampled at autopsy. The author gives the following list of etiological factors in secondary pyelonephritis: instrumentation, altered nephron architecture (intrarenal obstruction), extrarenal obstruction, pregnancy, diabetes, calculus or nephrocalcinosis, congenital anomaly, trauma, hypogammaglobulinemia, properdin deficiency, defective general resistance, and foci of infection—a source of bacteremia. The histological spectrum of pyelonephritis, largely gathered from biopsy material, is presented. Twenty-one different presenting syndromes are briefly described and represent the clinical spectrum of chronic pyelonephritis.

Waldenström's Macroglobulinemia: Clinical and Pathological Report of a Case Resembling Multiple Myeloma. J. W. Hampton. New England J. Med. 258:1293-1296 (June 26) 1958 [Boston].

The author reports on a 68-year-old patient with the classic features of Waldenström's macroglobulinemia who was admitted to the Medical Center of the University of Oklahoma in Oklahoma City. The patient had progressive pancytopenia, hyperglobulinemia, and a hemorrhagic disorder. There was a macrocytic normochromic anemia with an increased number of reticulocytes, a relative lymphocytosis, and a reduced number of platelets. The clot-retraction time was prolonged, and the petechiometer test was positive, but the bleeding, prothrombin, and clotting times were normal. The urine was negative for the Bence Jones protein test. Hyperglobulinemia and abnormal cephalin flocculation were notable. The bone marrow contained large mast cells in which dense nuclear chromatin was irregularly clumped with pale-staining nucleoli. Biopsy of an axillary lymph node was performed, and the findings were interpreted as indicating reticulum-cell hyperplasia. Because of the tentative diagnosis of multiple myeloma, urethan was prescribed but was ineffective. Hemorrhage continued to be a problem, and transfusions were frequently given. The failure to demonstrate skeletal lesions and the unusual appearance of the bone-marrow aspirations suggested the possibility of Waldenström's macroglobulinemia. The Sia water test subsequently carried out gave positive results. A heavy white flocculum, formed when a drop of the patient's serum was added to distilled water, prompted an analysis of the serum by ultracentrifugation. Twenty per cent of the total protein was shown to be a macroglobulin with a Svedberg constant of 19. The patient died after an illness of only 8 months' duration, death resulting from a massive intracranial hemorrhage. On gross and microscopic postmortem examinations the most striking finding was the widespread presence of hemorrhages involving all organs.

Treatment for Waldenström's macroglobulinemia was unsatisfactory in this patient and in others whose cases were collected from the literature. Splenectomy and the administration of urethan and antimetabolites useful in leukemia have all been tried. At best there is only temporary reversal of some of the clinical manifestations. Supportive therapy, especially transfusions to relieve the profound anemia, is recommended.

Phenprocoumon (Marcumar): I. An Agent for Short-Term Anticoagulant Therapy. E. McC. Priest and H. G. Pauli. Am. J. Cardiol. 2:61-70 (July) 1958 [New York].

Koller and Jakob reported from Switzerland in 1953 that the prothrombin time value and blood factor 7 can be maintained at a constant level with phenprocoumon (Marcumar). Data regarding this drug have appeared in the European literature, but phenprocoumon is little known in this country. Priest and Pauli describe observations on 160 patients who received phenprocoumon as an agent for short-term anticoagulant treatment in the Henry Ford Hospital in Detroit. The effects of different initial doses of phenprocoumon were studied in 134 patients. The drug proved to be a potent anticoagulant. Thirty to 36 mg. of phenprocoumon produced the desired hypocoagulability of the blood as promptly as an initial dose of 51 mg., when these doses were followed on the second and third day, depending on findings in the Quick test, by doses which ranged up to 9 mg. After therapeutic levels (prothrombin complex time, 25 to 35 seconds) had been reached, these were maintained with daily doses of phenprocoumon of 3 or 4.5 mg. Both low and excessively high prothrombin time values were only rarely encountered with this dosage range. Thus, in general, the desired depression of the blood clotting mechanism was easily maintained.

The incidence of hemorrhagic complications was 3.75%. Vitamin K_1 (Mephyton or Konakion) was an effective antagonist against undue depression of the blood clotting mechanism. These findings were compared with those reported by the Swiss workers and by American and British students. It is concluded that phenprocoumon is an effective agent for short-term anticoagulant therapy and that selected therapeutic prothrombin time values can be maintained with comparative facility.

Familial Mediterranean Fever. H. Heller, E. Sohar and L. Sherf. A. M. A. Arch. Int. Med. 102:50-71 (July) 1958 [Chicago].

The authors describe a disease which they define as a heredofamilial syndrome of undertermined pathogenesis in persons of Mediterranean stock; it becomes manifest, as a rule, in infancy or adolescence and is characterized by short recurrent bouts of fever accompanied by pain in the abdomen or chest or one or more multiple joints, singly or in various combinations. Sometimes erysipelas-like erythemas appear. A certain number of cases terminate fatally through supervening renal involvement. This is not a new disease, nor were the authors the first to describe it. Typical examples have been described especially in French papers of the last decade. Various names have been attached in the case reports, the best known of which are probably "benign paroxysmal peritonitis" and "periodic disease." With the aid of certain diagnostic criteria, the authors selected out of a mass of heterogeneous observation cases characteristic of a syndrome to which they applied the term "familial Mediterranean fever." To these cases they added 74 new ones observed by themselves.

The entity is of rather frequent occurrence with definite heredofamilial features among ethnic groups of Mediterranean stock. The authors describe the clinical picture and the laboratory findings of the syndrome, its chronicity, and its characteristic recurrent attacks of fever, with painful manifestations in abdomen, thorax, joints, and skin. In a certain percentage of cases the relentless course and the frequent renal involvement terminate in amyloidosis and death. Data on the pathological anatomy, etiology, and pathogenesis are meager, and the authors give reasons why they consider the disorder as belonging to the group of racially linked heredofamilial diseases with an inborn biochemical error. The clarification of the many problems in the etiology and pathogenesis of the disorder will be advanced by its recognition as a separate entity, distinct from the various conditions described as "periodic disease." Commenting on the term "benign paroxysmal peritonitis," the authors say that the disorder is far from benign and that it is not acceptable to place the entire emphasis on the abdominal crises. The term "familial Mediterranean fever" is suggested as a solution to the problem of terminology until more basic etiological and pathogenetic facts become known.

SURGERY

Control of Complete Heart Block by Use of an Artificial Pacemaker and a Myocardial Electrode. W. L. Weirich, M. Paneth, V. L. Gott and C. W. Lillehei. Circulation Res. 6:410-415 (July) 1958 [New York].

The combined use of an artificial pacemaker and a myocardial wire electrode has been demonstrated to be an effective method of controlling the heart rate at low voltages and low-current amplitudes. The cardiac output and mean aortic pressures of dogs have been restored to preblock levels through the application of repetitive electric stimuli to the ventricular myocardium. No complications from insertion or removal of the wire in the myocardium were noted. The heart rates of 18 patients with complete heart block after closure of septal defects have been successfully controlled with this method. This effective control of postsurgical heart block has been the single most important contribution to the rapidly decreasing mortality of open heart surgery.

The Treatment of Congenital Aortic Stenosis with Valvotomy During Cardiopulmonary Bypass. F. C. Spencer, C. A. Neill and H. T. Bahnson. Surgery 44:109-124 (July) 1958 [St. Louis].

The authors present their experiences with cardiopulmonary bypass in the surgical treatment of 12 patients with congenital aortic stenosis. This lesion is receiving more attention because of the possibility of operating on these patients under direct vision. The earlier treatment with dilators introduced through the ventricle without direct vision was not generally satisfactory because of the fibrous type of stenosis encountered and because of the danger of producing aortic insufficiency. The interest of these authors in the surgical treatment of this lesion has recently heightened because of the sudden death of children with few preceding symptoms or signs other than electrocardiographic abnormalities and because of the increasing conviction that fibrous stenosis in children progresses to calcific stenosis in adults with worsened prognosis and decreased possibilities of adequate surgical treatment. There were 11 males and 1 female in the series. The ages at operation ranged from 3 to 19 years; 1 patient was under 5 years, 1 between 5 and 10 years, 6 between 10 and 15 years, and 4 over 15 years. The patients had been followed preoperatively in the Harriet Lane Home cardiac clinic in Baltimore for between 1 and 19 years; 6 patients had been followed for more than 5 years. A cardiac murmur was detected during the first year of life in all but 3 patients in whom it was heard at 2, 3, and 5 years respectively. Most patients were completely asymptomatic during infancy and early childhood.

The 12 patients with congenital aortic stenosis were successfully treated by incision of the stenotic area during cardiopulmonary bypass with potassium-induced cardiac arrest. The stenosis was valvular in 8 patients and subaortic in 4. All the patients were diagnosed preoperatively as having aortic stenosis, but in only 1 of the 4 subvalvular cases was the exact site of stenosis recognized. In retrospect the diffuse quality of the systolic thrill, the presence of left axis deviation, and the presence of a greater degree of cardiomegaly than usual may all be possible pointers to a subvalvular site. Ventricular fibrillation in 6 of the 12 patients was easily treated with electrical defibrillation. Fused commissures were present in each stenosed valve; these were opened by incision along the center of the fused commissure. The type of commissural fusion was surprisingly similar in all 8 patients with valvular stenosis. Moderate insufficiency followed valvotomy in 2 patients. The results indicate that aortic valvotomy may be done with cardiopulmonary bypass with low risk and satisfactory results. Early operation should be considered in children with symptoms and progressive changes in the electrocardiogram of left ventricular hypertrophy with ST depression and flattening or inversion of T waves over the left precordium.

Clinical and Hemodynamic Observations in Pure Mitral Insufficiency. J. Ross Jr., E. Braunwald and A. G. Morrow. Am. J. Cardiol. 2:11-23 (July) 1958 [New York].

Mitral insufficiency not accompanied by other valvular lesions is relatively uncommon. This report is concerned with the clinical and hemodynamic findings in 23 patients with pure mitral insufficiency. Electrocardiographic, roentgenographic, and clinical features in the 10 patients with pulmonary hypertension are contrasted with findings in the patients without pulmonary hypertension. In the former group pulmonary vascular resistance was elevated, and clinical evidence of right heart failure was frequently present. In general, marked fatigability was noted in patients with abnormally low resting cardiac outputs. The left atrial pressure pulse contour was characteristic in 20 patients; similar changes in the left atrial pressure contour occurred in the remaining 3 patients after the infusion of arterenol. Left atrial pressure contour analysis proved to be of considerably greater diagnostic value than analysis of the pulmonary capillary wedge pressure tracing. Left atrial Z-point pressures were significantly elevated in 17 of the 23 patients, and left ventricular and diastolic pressures were elevated in 7 of the 12 patients. Histological examination of the lungs in 4 patients with pulmonary hypertension showed extensive proliferative changes in the pulmonary vasculature.

Pulmonary Tuberculosis and Peptic Ulcer. E. Waingortin and H. J. Lorge. Dis. Chest. 34:55-59 (July) 1958 [Chicago].

The authors analyze observations on 27 patients with pulmonary tuberculosis at the Worcester County Sanatorium, Worcester, Mass., in whom peptic ulcer was demonstrated either before admission or during the course of hospitalization. Roentgenologic proof of the ulcer was available in all cases. The patients are divided into 4 groups. The first group includes 12 patients in whom tuberculosis developed after surgical treatment for peptic ulcer; 9 had been subjected to total or subtotal gastrectomy, 2 to gastroenterostomy, and 1 to "closure" of a gastric ulcer, but this patient required gastrojejunostomy at a later admission. The interval between abdominal surgery and onset of tuberculosis ranged from less than 1 year to 37 years. In the second group of 4 patients gastrointestinal symptoms appeared after surgical treatment of pulmonary tuberculosis by thoracoplasty. The interval between operation and discovery of the peptic ulcer varied from 4 months to 7 years. There were 3 duodenal ulcers and 1 gastric ulcer. These patients also had received chemotherapy including *p*-aminosalicylic acid before the onset of abdominal symptoms. In 1 patient a gastric ulcer developed in the wake of cortisone therapy for severe rheumatoid arthritis. The third group included 7 patients in whom pulmonary tuberculosis preceded the onset of peptic ulcer; the latter was discovered at autopsy in 3. Six patients had received oral chemotherapy before the ulcer manifested itself. In the 4 patients of the fourth group, as in the first, the ulcers, 1 gastric and 3 duodenal, preceded the onset of tuberculosis, but the treatment of the ulcer was medical rather than surgical.

The authors believe that tuberculous patients, in whom gastrointestinal symptoms develop after thoracic surgery, oral chemotherapy, and especially after *p*-aminosalicylic acid medication, should be investigated for peptic ulcer. Patients in whom gastrectomy is to be carried out for peptic ulcer should have chest x-ray films made before operation. If a pulmonary lesion is found, the presence of active tuberculosis should be investigated, and after the operation the pulmonary lesion should be kept under careful observation, not only during the immediate postoperative period but also later. Finally, a chest x-ray film should be part of the check-up examinations of all patients who have undergone gastrectomy.

Intrarenal Arteriovenous Fistula with Hypertensive Cardiovascular Disease: Review of the Literature. F. Milloy Jr., E. H. Fell, R. F. Dillon and A. M. Zayas. Am. J. Surg. 96:3-11 (July) 1958 [New York].

Arteriovenous fistulas of the renal vessels are of particular interest because of their ability to produce not only the systemic effects of an arteriovenous fistula but also, theoretically, those of a Goldblatt kidney. That intrarenal arteriovenous fistula is a rare lesion is proved by the fact that the authors were able to find only 11 cases reported in the literature; 6 of these were congenital, 4 were acquired, and 1 was of undetermined etiology. They believe that the case observed by them is the 12th recorded of intrarenal arteriovenous fistula and the 3rd of traumatic etiology.

The patient was a 32-year-old woman who was hospitalized because of dizziness and headaches of 8 years' duration, ankle edema, and easy fatigability of 5 months' duration. More recently she had also noted vague substernal pain. She had been treated for high blood pressure for 6 years. Her past history included a story of having injured herself in the left flank when she fell on a knife at the age of 10.

At the time of this accident the bleeding was stopped by means of a skin clip. Because of the heart failure and decreasing cardiac reserve, surgical intervention was elected. The left kidney was explored. The renal artery and vein were dissected as far as possible into the substance of the kidney hilus in the hope that the fistula could be identified and closed without nephrectomy. When it became apparent that the fistula was well within the kidney parenchyma, nephrectomy was performed. The patient had an uncomplicated postoperative course. Today she no longer has symptoms of cardiac failure. However, her blood pressure has remained moderately elevated during the first postoperative year.

Although arteriovenous fistulas of other systemic vessels do not produce a significant hypertension, those of the renal vessels may. Clinical opinion indicates that there may be ischemia distal to an arteriovenous fistula, and experimental evidence indicates that there is ischemia and decreased pulse pressure distal to an arteriovenous fistula. The authors believe that the hypertension associated with renal arteriovenous fistula, particularly of acquired etiology, may be on the basis of a Goldblatt effect resulting from the altered renal hemodynamics produced by the fistula.

Splenic Arterial Aneurysm. J. N. Ward-McQuaid. Brit. M. J. 2:1448-1452 (June 21) 1958 [London].

The most common pathogenetic factor in splenic artery aneurysm is arteriosclerosis followed, in order of frequency, by embolic phenomena, portal hypertension, congenital causes, trauma, and infection. Five cases of operative removal of splenic aneurysms are reported. One death followed rupture of an aneurysm, and 1 recovery after rupture is reported in a pregnant woman. In the 3 patients with unruptured aneurysms, the diagnosis was made by the roentgenologist prior to operation, and these patients survived. The treatment of choice in this condition is resection of the artery and splenectomy.

Acute Emphysematous Cholecystitis: A Case Report and Review of the World Literature. A. Edinburgh and A. Geffen. Am. J. Surg. 96:66-75 (July) 1958 [New York].

The authors are concerned with the clinical and pathological entity that has been described under such terms as "acute pneumocholecystitis," "pyopneumocholecystitis," "acute gaseous cholecystitis," "gas gangrene of the gallbladder," and "emphysematous cholecystitis." They present a new case and review the 49 cases previously reported in the literature. A 62-year-old woman was hospitalized with a 4-to-5-day history of severe, intermittent abdominal pain in the right upper quadrant associated with interscapular radiation. She had been receiving antibiotic therapy at home for several days. Seven or 8 years previously attacks of epigastric pain had developed, radiating to the interscapular area. Since then these attacks had recurred intermittently, usually clearing within 24 hours. Roentgenologic examination of the abdomen, particularly of the gallbladder region, revealed gas within the lumen and the walls of the gallbladder. Emphysematous cholecystitis was thought of, since roentgenologic examination on the following day again showed the gallbladder filled with gas which extended into the wall. The film taken with the patient erect showed a fluid level within the gallbladder. Mottling within the lumen was suggestive of radiolucent calculi. Films taken 2 weeks later showed a decrease in the amount of air in the gallbladder. The patient never appeared acutely ill.

The patient was readmitted 6 weeks after the onset of the acute attack for an operation. A large inflammatory mass was found to occupy the right subhepatic space, and a subhepatic pericholecystic abscess was suspected. The omentum was separated from the liver in the vicinity of the gallbladder, which was not immediately visualized. An abscess containing a few ounces of pus was entered. When the abscess cavity had been evacuated, a structure resembling the gallbladder could be seen lying freely within it. When lifted out, this structure was found to be the gallbladder containing stones. There were no stones in the pericholecystic abscess. The gallbladder apparently had not grossly perforated. A catheter was placed down to what appeared to be the cystic duct and was sutured in place. A cigarette drain was also placed in the abscess cavity. The patient was discharged after 16 days.

Of the 49 cases of acute emphysematous cholecystitis in the literature, only 7 were reported before 1940. Bacteriological studies revealed a wide range of organisms. Anaerobic cultures, despite their importance, were not taken in at least 11 instances. Clostridium organisms were noted in about 40% of the cases, and Escherichia coli in 30% of those in which cultures were taken. Acute emphysematous cholecystitis is a rare pathological condition of the gallbladder, characterized by the growth of gas-producing organisms within that organ, the seat of an acute cholecystitis. The presenting clinical picture is usually indistinguishable from that of an acute cholecystitis. The diagnosis is made by roentgenologic studies of the abdomen, which demonstrate the gallbladder distended with air in its lumen and within its wall. Operation within the first 24 to 72 hours after onset of symptoms, with cholecystectomy, if technically feasible, is the treatment of choice. However, conservative management with the use of large doses of antibiotics has led to satisfactory results in the few patients so treated.

Stump Carcinoma Following Gastric Resection for Ulcer. C. DeBray, M. Bouvry and P. Roches. Schweiz med. Wchnschr. 88:631-634 (June 28) 1958 (In German) [Basel, Switzerland].

The authors discuss the problem of stump carcinoma after gastric resection for peptic ulcer. Eleven cases observed since 1950 at the Hospital Bichat, Paris, and 113 cases collected from the literature comprise this report. The interval between resection and the occurrence of symptoms ranged between 5 and 37 years, with a mean average of 14.9 years. Dysphagia constantly appeared as the initial symptom and was associated with regurgitation and other elements of the esophageal syndrome, such as retrosternal pain and excessive salivation. A relapse with long symptom-free intervals was not uncommon. Hematemesis was the initial sign in 4 instances. Asthenia, emaciation, and anemia were present at the first indication of difficulty. A palpable tumor was a late symptom, and anemia was recognizable only when it was quite severe. The source of carcinoma of the stump was often difficult to determine. In 49 of the 113 cases reviewed, it arose from the stump itself, in 31 it arose at the mouth of the anastomosis, in 13 other cases specific information as to the point of origin was lacking, and in the remaining 20 cases gross extension of the tumor did not permit accurate localization. The tumor was located in the vicinity of the cardia or in the fornix in 16 of the latter cases, and in 8 of the 11 cases actually observed by the authors. This form of carcinoma is more frequent than previously supposed and occurs more often after resection for perforating ulcer than in the stomach not operated on, usually growing on the greater curvature or in the vicinity of the cardia. Although the diagnosis can be accomplished by roentgenography, gastroscopy, and ultimately biopsy, the prognosis is uniformly poor.

Ruptured Aneurysm of the Splenic Artery. C. L. James. Am. J. Surg. 96:18-23 (July) 1958 [New York].

A 62-year-old woman had been treated for moderate hypertension for several years. The present illness started with a sudden severe pain in the upper abdomen, and the patient was hospitalized about 2 hours after the onset. The pain became more generalized and radiated into the back and left shoulder; during the night the abdominal pain was partially relieved by narcotics. The following morning, as the patient was expelling an enema given in preparation for a colon study, she went into collapse. It became apparent that a major intra-abdominal hemorrhage was occurring, and immediate laparotomy was advised. With the patient under general anesthesia, with several simultaneous transfusions, the abdomen was opened through a long midline incision. Blood gushed forth in great quantities. The brightest blood appeared from the left upper quadrant of the abdomen, and compression of the splenic pedicle slowed but failed to stop the hemorrhage. Continued pressure of the splenic pedicle and compression of the abdominal aorta below the diaphragm controlled the hemorrhage. When the aorta was released, blood was seen to spurt from a ruptured aneurysm in the midportion of the splenic artery. The aneurysm was thin-walled, saccular and appeared to be about 2.5 cm. in diameter. The splenic vessels were ligated proximally; the spleen and aneurysm were removed.

This case, although not diagnosed preoperatively, presents many classic features of ruptured splenic artery aneurysm. It is the 10th reported case of this rare and usually fatal condition with surgical recovery. When rupture occurs, it is usually fatal, unless aggressive surgical treatment is promptly initiated. The diagnosis before rupture is very difficult, unless the lesion is kept in mind and a pulsating mass is palpable or the aneurysm is demonstrable roentgenologically. Rupture may be suspected if there is initial sudden severe pain in the left upper quadrant, with mild shock followed by a temporary period of improvement and then sudden and almost complete collapse with findings characteristic of massive intra-abdominal hemorrhage. The treatment of choice is massive transfusion and supportive measures with prompt removal of the ruptured aneurysm and spleen.

Hemangioendothelioma of Stomach. B. Andreassen. Tidsskr. norske lægefor. 78:522-523 (June 1) 1958 (In Norwegian) [Oslo].

Hemangioendotheliomas are malignant vascular tumors in which proliferation of endothelial cells dominates. The tumors belong to the sarcoma group and are rare but can occur in various places, including the stomach. The symptoms here are not characteristic. They resemble the symptoms in carcinoma of the stomach. Hemangioendotheliomas, like other sarcomas in the stomach, are soft tumors with little tendency to obstruct the stomach lumen. The patient's general condition is affected less than in carcinoma. Free hydrochloric acid is often present in the stomach. A probable diagnosis can be made only by comparing the clinical and roentgenologic findings. Treatment is surgical. Partial gastric resection or a total gastrectomy and removal of possible metastases to the lymph nodes give results far better than those in carcinoma. In the case reported, in a woman aged 64 years, with a history of duodenal ulcer 8 or 9 years earlier, symptoms of the hemangioendothelioma had been present for 10 months before the operation. Roentgenologic examination of the stomach and duodenum was made 3 times before tumor infiltration was diagnosed. The benzidine reaction in the feces was positive. Anemia gradually developed, but in the main the general condition was good, with little loss of weight. There was free hydrochloric acid in the stomach. Radical removal of the tumor was possible, and since no signs of metastases were found, the prognosis has been considered good.

Inverted Electrolyte Response Following Total Adrenalectomy. J. G. Llaurado and V. T. Pearse. Metabolism 7:301-314 (July, pt. 1) 1958 [New York].

The authors point out that most of the theoretical arguments which deny a leading role to the adrenal cortex in the metabolic changes seen after trauma originate from the concept of "permissive action" elaborated earlier by Ingle in an attempt to give a rational explanation of the perplexing observation that the metabolic response which occurs after experimental fractures in intact rats occurs also in adrenalectomized rats maintained on a constant amount of adrenocortical extract. The paper deals with the changes in electrolyte excretion in 2 patients subjected to total adrenalectomy and presents a comparison between the response to removal of one adrenal with no steroid replacement and that to removal of the remaining adrenal with a minimal maintenance dose of corticoids consistent with safety. To illustrate better the significance of these results, they are compared with data on a patient subjected to total adrenalectomy and given large doses of a corticoid and on patients undergoing operations which did not involve the adrenal. The 3 patients subjected to adrenalectomy were all women who had undergone radical mastectomy earlier for carcinoma of the breast. On coming to the hospital, they all presented widely disseminated metastases, and bilateral adrenalectomy and oophorectomy offered a reasonable hope of palliation.

The first patient was maintained exclusively with 9α-fluorocortisol acetate. At the time this patient was studied little was known about the adequate dosage of this compound, and retrospectively it was realized that too large amounts of the 9α-fluorocortisol acetate had been given. It was also realized that the drug alone does not provide an adequate corticoadrenal replacement, because its cortisol-like effect is too small in comparison with its aldosterone-like effect. The corticoid replacement for the other patients was specially designed to investigate their electrolyte response. Twenty-four-hour collections of urine were made during the whole period of study, starting one or more days before each operation. The sodium and potassium ion estimations in urine and in serum were made with flame photometer. The urine electrolyte values were expressed in terms of the sodium/potassium ratio, since it has been shown that this ratio is the most accurate and sensitive index of aldosterone-like activity. After the removal of the first adrenal, conducted without steroid replacement, there was a considerable fall in the urine sodium/potassium ratio, reflecting increased aldosterone secretion. This fall is a common feature of the normal pattern of the metabolic response to surgery. After the second adrenalectomy and maintenance with minimal dose of corticoids, the decrease in this ratio was not observed; indeed, there was a marked elevation of the sodium/potassium ratio. It is concluded that hyperactivity of the adrenal cortex in the form of increased aldosterone secretion is the principal factor responsible for the electrolyte changes which occur after surgical trauma. It is suggested that previous contradictory results obtained by other workers were due to administration of large doses of cortisone, to cumulative effects of cortisone given intramuscularly preoperatively, or to both.

NEUROLOGY & PSYCHIATRY

Peroneal Paralysis—A Hazard of Weight Reduction. B. E. Sprofkin. A. M. A. Arch. Int. Med. 102:82-87 (July) 1958 [Chicago].

It has long been known that weight loss is an important predisposing factor in the development of a pressure paralysis of the peroneal nerve, often referred to as "leg-crossing palsy." The almost universal interest in reduction diets and a coincidental disposition to spend long hours sitting with crossed legs before a television set may lead to an increasing incidence of peroneal paralysis due to compression and manifested by foot drop. Nine illustrative cases are presented to emphasize the history of this benign neurological disorder which must be differentiated from more serious disorders of the nervous system. The author briefly describes the anatomy of the common peroneal (external popliteal) nerve and its branches, the deep and the superficial peroneal nerves. The superficial peroneal branch innervates the peroneus longus and brevis, which evert the foot. Since the deep peroneal branch innervates the dorsiflexors of the feet and the extensors of the toes, a foot drop will result when its function is interrupted. The exaggerated elevation of the knee to enable the affected foot to clear the ground and its subsequent slap as it strikes the ground result in the diagnostic "steppage gait." In most of the cases of peroneal nerve compression associated with leg crossing, the common peroneal nerve seems to be involved rather than one of its divisions. When the common peroneal nerve is injured, the affected foot cannot be dorsiflexed at the ankle, nor can its toes be extended, owing to involvement of the deep peroneal branch. There is also inversion of the foot, since the peroneal muscles supplied by the superficial peroneal nerve are also affected. This combination of paralyzed muscles usually leaves the foot in an equinovarus position.

Wherever a peripheral nerve is superficially situated, it is susceptible to damage by compression. In only 2 patients in this series was there a history of alcoholism, and in neither of these patients was there any evidence of other neuropathy. Diabetes was not present in any of these cases. The foot drop was on the left in 5 cases, on the right in 2, and bilateral in 2. The average age of the patients was 54, and 8 of the 9 patients were more than 50 years of age. The average weight loss was about 25 lb. (11.3 kg.). Three patients were convalescing from a myocardial infarction, and 2 others were being treated by a psychiatrist for depression. With respect to differential diagnosis, it is important not to confuse this relatively unimportant mononeuropathy with cerebral vascular disease or spinal cord neoplasm, on the one hand, and psychoneurosis, on the other.

Study of the Incidence of Multiple Cases of Poliomyelitis in One Family: Anamnestic Contribution. S. Scarabicchi. Minerva pediat. 10:556-558 (May 19) 1958 (In Italian) [Turin, Italy].

The author reviews the records of 806 patients with poliomyelitis, who were hospitalized at the pediatric clinic of the University of Genoa during the past 5 years, in order to determine the incidence of multiple cases of poliomyelitis in individual families. One incidence of multiple cases of poliomyelitis involving 2 children in a family took place in 1953; no such incidence developed during 1954 and 1955; 5 incidences involving 2 children in each family (total of 10 patients) took place in 1956, and incidences involving 3 children in each of 2 families and 2 children in each of 3 families (total of 12 patients) took place in 1957. The author believes that the more frequent incidence of multiple cases of poliomyelitis in recent years has not been incidental, or related to the increase of the incidence of poliomyelitis in general, but can be attributed to the presence of more virulent strains of poliomyelitis virus than in the past.

Effects of Cortisone and ACTH in Mumps Meningo-Encephalitis. J. K. Spitznagel. Ann. Int. Med. 49: 61-69 (July) 1958 [Lancaster, Pa.].

The author reports on 5 men, between the ages of 20 and 37 years, with mumps meningoencephalitis who were admitted to the communicable disease ward of the U. S. Army Hospital, Fort Bragg, N. C. The patients presented headache, drowsiness, and stiff neck; only 1 did not vomit. Nuchal rigidity and sialadenitis were observed in all. The patients were lethargic, and 3 were delirious. One patient had orchitis on admission. Temperatures ranged from 101 F (38.5 C) to 104 F (40 C). Pleocytosis was found in the cerebrospinal fluid of every patient; mononuclear cells were predominant in 4. Three patients had an elevated level of the protein content of the cerebrospinal fluid. In selecting these patients, an effort was made to obtain those with manifestations of central nervous system involvement of no more than 2 days' duration and with particularly severe symptoms and signs, including disturbances of the sensorium. Rises in complement-fixing antibody for mumps antigen in the serums were consistent with recent infection in 4 patients from whom acute-and-convalescent-phase serums were obtained. Diagnoses were confirmed by lumbar puncture. Four patients were given cortisone in doses of 200 to 300 mg. per day, and 1 patient was given corticotropin (ACTH) in doses of 60 mg. per day. In all patients but one administration of the drugs was discontinued by progressive decrements.

Cortisone and corticotropin appeared to produce rapid remission of headache, nausea, anorexia, vomiting, lethargy, delirium, and nuchal rigidity. Fever, although it fell rapidly, tended to return to previous levels for short periods of time, accompanied by minor recurrence of other symptoms. Orchitis developed in one patient during cortisone therapy. This patient, and one other, had additional salivary gland involvement during therapy. Abrupt withdrawal of the drug in one patient after the administration of 3 doses of cortisone resulted in a dramatic recurrence of previous symptoms. The duration of mumps in these patients was not shown to differ from that in patients not receiving cortisone or corticotropin. No evidence of residual disease of the nervous system could be detected in any of these patients. This study did not provide any basis for the explanation of any effects which cortisone or corticotropin may have had on the patients.

Deficiency Encephalopathies of Alcoholic Subjects. J. Lapresle. Semaine hôp. Paris 34:1629-1637 (June 4) 1958 (In French) [Paris].

The deficiency encephalopathies of alcoholic subjects appear in 3 principal forms: (1) Wernicke's disease, which associates in an acute course constant psychic disturbances of a confusional type with less constant neurological signs (disturbances of balance, extrapyramidal disturbances, and ocular signs); (2) Korsakoff's syndrome, with its characteristic disturbances of memory and its subacute or chronic course; and (3) Marchiafava-Bignami disease, with which Morel's cortical sclerosis may be grouped because of the similarity of their clinical signs, consisting essentially of dementia, and their rapidly fatal course. All 3 forms are characterized by glial and vascular changes and by neuronal lesions of the retrograde type, so that differences in the distribution of the lesions, rather than in the lesions themselves, govern the clinical type. The basic etiological element in these conditions is a deficiency of vitamin B_1. Correction of this deficiency by vitamin B_1 administration, if it is started in time, produces results that are always favorable and often dramatic. Vitamin B_1 therapy must therefore be tried even when the diagnosis is merely suspected. It is generally agreed that the doses should be large, from 500 to 1,000 mg. a day, and that they should be given by the intramuscular route, because serious complications have been reported after the intravenous injection of massive doses. The basic treatment with vitamin B_1 should be supplemented by administration of the other fractions of the B complex and by vitamins C and K, both because of the possibility of associated deficiencies in these substances and because of their own pharmacodynamic effect.

Treatment with alcohol, which is effective in delirium tremens, is contraindicated in these deficiency conditions, because it is of no value—quite the contrary. Sedatives, too, are generally useless in these patients who are for the most part calm and already confused. A balanced diet (not too rich in glucides), on the other hand, is essential, and provision must be made for rehydration and correction of electrolyte imbalance. Neuroplegic medicaments should be given as required for the neurovegetative syndrome. Corticotropin and cortisone seem, for reasons not yet understood, to have a favorable effect, particularly in the chronic forms, especially Korsakoff's syndrome. They should, of course, be given with all the usual precautions and under the protection of antibiotics, which is indispensable for these peculiarly fragile patients. The radical improvement made by vitamin B_1 therapy in the prognosis of these conditions, especially Wernicke's disease, which he regarded as invariably and rapidly fatal, emphasizes anew the importance of accurate early diagnosis.

Paramyotonia Congenita. G. A. Drager, J. F. Hammill, and G. M. Shy. A. M. A. Arch. Neurol. & Psychiat. 80:1-9 (July) 1958 [Chicago].

Paramyotonia is a relatively rare disorder, as only 2 pedigrees of the disease are to be found in the literature. The authors present an additional pedigree with 30 affected members. Features warranting delineation of Eulenberg's paramyotonia as a specific syndrome are presented. Six generations of a family of 115, with 30 members showing traits of paramyotonia congenita, have been investigated. Males and females are equally dispersed among the 30 affected members. Some members of every generation are affected, although, should any one member of a generation fail to exhibit the trait, it disappears from all of his or her succeeding offspring. The over-all genetic pattern indicates a single dominant autosomal strain with nearly complete penetrance and thus conforms favorably with the pedigrees of paramyotonic families described by Eulenberg. It further indicates that the least affected members of the family are more likely to give rise to unaffected offspring in contradistinction to the more severely affected members who characteristically give rise to affected offspring.

A review of the literature and the 4 cases presented would indicate that paramyotonia is a separate clinical entity consisting of the triad of myotonia, increasing in the presence of cold; intermittent flaccid paresis, not necessarily dependent upon cold or the presence of myotonia; and a hereditary pattern dependent upon a single autosomal dominant gene. Excessive lability of serum potassium appears to be constant in all cases, although no shift of intracellular potassium is indicated.

Fatal Mistakes in Diagnosis of Cerebral Apoplexy. J. Marquardsen. Ugesk. læger 120:663-670 (May 22) 1958 (In Danish) [Copenhagen].

Autopsy revealed an undiagnosed intracranial tumor in 6 of 291 patients who died in a neurological department under the diagnosis of cerebral apoplexy and a subdural hematoma. The errors in diagnosis were almost exclusively in patients aged over 65 years, in whom the usual signs of increased intracranial pressure were absent. In some of the patients timely operation would doubtless have been lifesaving; subdural hematomas are generally operable, but the unrecognized tumors were chiefly malignant gliomas. A purely clinical diagnosis of apoplexy should be supplemented by special diagnostic adjuvants. Cerebral angiography is the only procedure which can with reasonable certainty establish or exclude a tumor or subdural hematoma and at the same time establish a cerebrovascular accident. In the diagnosis of apoplexy arteriography should be applied to a far greater extent than has been done heretofore. When facilities for cerebral angiography are not at hand, attention should be focused on the manner of development of the symptoms. An expanding lesion should be suspected on insidious onset of symptoms, progressive development of focal signs, remarkably rapid mental deterioration preceding the focal symptoms and persisting torpidity or somnolence with only mild focal signs and good general condition. The diagnostic efforts should not be relaxed in the case of patients in whom in advance a vascular accident seems probable, and even an accumulation of factors predisposing to apoplexy, such as advanced age, arteriosclerosis, and hypertension, does not exclude the presence of a tumor or subdural hematoma. For an adequate diagnosis of apoplexy, intimate cooperation among medical, neurological, and neurosurgical departments is called for.

GYNECOLOGY & OBSTETRICS

Ovariectomy and Adrenalectomy in Metastasizing Mammary Cancer. J. Hellström. Nord. med. 59: 769-773 (June 5) 1958 (In Swedish) [Stockholm].

From January, 1953, to November, 1957, bilateral adrenalectomy was performed in the Karolinska Sjukhus on 214 patients with metastasizing cancer of the breast. Most of the patients had received roentgen-ray or hormonal treatment earlier. Surgical deaths occurred in 2.3% of the cases, postoperative deaths in hospital in 7.3%. Of the 166 patients operated on up to March 31, 1957, 150 were observed for at least 2 months after the operation; in 143 of these ovariectomy had also been done. Remission was seen in 76 patients, or 51%. Forty-two of the patients lived 1 year or longer. There was no certain difference between those operated on before or after the menopause. The patient's age apparently was not significant. The localization of the metastases was of greatest importance. The results were better in patients with metastases located in the skin, lymph nodes, pleura, and skeleton than in those with metastases in the viscera, especially the liver, and in the brain. In 23 cases ovariectomy had been considered unnecessary because of the patient's age, but comparison of the frequency of remission in the patients in whom ovariectomy was not carried out and in those with both ovariectomy and adrenalectomy showed definitely lower values where ovariectomy was not done, which seems to indicate that the ovaries play a part in the growth of the cancer even in older and roentgen-ray-castrated women. Bilateral ovariectomy and adrenalectomy in metastasizing mammary cancer are an intervention which can be performed with little primary mortality and resulting subjective improvement in more than 80% of the patients and objectively observed remission of the cancer development in more than 50%.

The Cytological Examination of Nipple Discharges as a Diagnostic Aid. J. C. Walker and A. T. Sandison. Scottish M. J. 3:297-304 (July) 1958 [Glasgow].

The authors present results obtained with cytological examination of the nipple discharge and subsequent operation on 25 patients, all of whom have been followed for at least 3 years. Included in this group were patients whose primary complaint was discharge from the nipple alone, as well as those patients whose discharge was secondary to a clinically evident lesion. Eighteen of the patients had no physical sign other than discharge from the nipple. The cytology of mammary secretion is not complicated by the presence of normally desquamated cells, as in examination of sputum or vaginal smears. Most of the cells are probably of ductal origin. Many discharges are relatively acellular, while in true inflammatory lesions there may be amorphous debris accompanied by leukocytes and sometimes red blood cells. The presence of red blood cells must always be regarded with suspicion, and in such smears a careful search must be made for clumps of or individual epithelial cells. If fixation is not good, there must be caution in estimating the nature of the parent lesion. In papilloma the cells are rounded or oval with large nuclei which are often deeply stained, while in intraduct carcinoma the cells and nuclei may vary in size and shape and be accompanied by naked nuclei or nuclear debris. In conditions where the pathological change does not involve the duct-acinus system, there can be no evidence of its presence in the discharge.

The ages of the patients examined ranged from 14 to 68 years. The lesions responsible for the discharge were in 1 patient intraduct papilloma, in 4 patients papillomatosis, in 11 mastopathy, in 4 carcinoma, in 3 infective mastitis, and in 2 fibroadenoma. In 14 patients cytological examination was of value; this was especially true where no information was obtained on ordinary clinical examination. The authors hope to encourage other surgeons to correlate histological and cytological examinations of the discharge. The need for biopsy may then become less frequent. Nothing can replace the accurate appraisal of clinical findings and judgment of the necessity for biopsy, but in many cases present diagnostic methods are insufficient, and the authors feel that the evidence produced by simple cytological study of nipple discharges is of value.

A Study of Epidemiologic Factors in Carcinoma of the Uterine Cervix. E. G. Jones, I. Macdonald and L. Breslow. Am. J. Obst. & Gynec. 76:1-10 (July) 1958 [St. Louis].

The authors present an epidemiologic study to determine the association of exogenous and endogenous factors in 429 patients with carcinoma of the uterine cervix. Only patients with invasive primary squamous-cell carcinoma were included in the study. Patients with preinvasive lesions as well as adenocarcinomas were excluded. Control patients (429) were selected from the same source as the patients without gynecologic disease or cancer of any site, with the same distribution of race and parity. To assure some degree of contrast in economic background, both "ward" and "private" patients were included. The study extended over a period of 4 years. The specific items of importance which have been under scrutiny are: dietary deficiency, estrogen excretion levels, menstrual patterns, hygienic practices, use of contraceptives, circumcision of marital and other partners, and frequency and duration of coitus. There were no significant differences between the cancer patients and the controls in total thiamine and riboflavin intake, in bathing habits, in sexual practice, in types and number of pregnancies, hygiene and coitus during pregnancy, manner of delivery, and bleeding or infection after pregnancy. Circumcision or lack of circumcision was as frequent in the partners of patients with cancer as in the partners of controls. A greater incidence of carcinoma in Gentiles over Jews as well as in women with syphilis, was again noted. Seven per cent of the cancer patients had clear-cut evidence of syphilis; only 4% of the control group had.

There is some evidence to show that a constellation of factors related to socioeconomic conditions and domestic and marital instability is more prominent in women who have carcinoma of the cervix than in comparable groups without this disease. The study, therefore, does not disclose any new specific causative factor for uterine cervical carcinoma. It does reemphasize the importance of the socioeconomic complex of relative poverty (at least in early life), with rapid maturation sexually and a haste to begin early, and early to terminate, the reproductive phase of biological destiny—marriage, intercourse, first and last pregnancies, separation, divorce. All these events occur significantly earlier in the life of the woman destined to develop carcinoma of the uterine cervix than in the woman without this disease in similar age distributions.

Constitutional Stigmas Associated with Endometrial Carcinoma. J. D. Garnet. Am. J. Obst. & Gynec. 76:11-19 (July) 1958 [St. Louis].

The high incidence of carcinoma of the endometrium in association with obesity, hypertension, altered carbohydrate metabolism, infertility, late occurrence of the menopause, hyperplasia of the endometrium, and irregular bleeding at the time of the menopause suggests a common metabolic disorder as an etiological factor. Glucose tolerance tests were performed on 50 randomly selected patients with proved endometrial carcinoma; they were both treated patients, as seen in the special tumor follow-up clinic, and new patients, as seen on admission to the hospital. For purposes of comparison, a control group of 50 women were given glucose tolerance tests. The patients in the control group were all 40 years of age or older; preexisting diabetes was unknown, and none had endometrial carcinoma. A third group of 12 women in whom an histological diagnosis of atypical or adenomatous hyperplasia of the endometrium had been made were also studied for glucose tolerance. The patients in all 3 groups were analyzed with regard to age, obesity, parity, hypertension, and age at the menopause.

One-third of the patients in the control group were classified as obese, while more than one-half of the patients of the group with endometrial carcinoma were obese. The incidence of obesity was found to be greater in patients with atypical endometrial hyperplasia. Only one-third of the control patients had blood pressures above 140 mm. Hg, systolic, and 90 mm. Hg, diastolic, while more than one-half of the patients with endometrial carcinoma had concomitant hypertension. The increased incidence of hypertension in patients with endometrial carcinoma is probably secondary to the obesity and lateral body build of these patients.

Nulliparity is almost twice as frequent in patients with endometrial carcinoma. The incidence of nulliparity in the patients with endometrial hyperplasia is only slightly higher than in the control group. The history of nulliparity and irregular bleeding during, or after, the menopause was a feature commonly noted in the patients with endometrial carcinoma. Such evidence of excessive estrogen stimulation, with resultant endometrial hyperplasia and polyp formation, is ascribed to prolonged and abnormal secretion of the follicle-stimulating hormone by the anterior pituitary gland. The occurrence of a high incidence of delayed menopause in patients with endometrial carcinoma was not noted in this study.

One-fifth of the patients in the control group demonstrated a diabetic type of glucose tolerance curve, the glucose tolerance curves in the remaining four-fifths being normal. Four of these cases can be classified as unquestionable diabetes, while the other 6 were of a questionable or mild type. In the group of 50 patients with proved endometrial carcinoma, approximately two-thirds had a diabetic type of glucose tolerance curve. One-half of these patients can be considered to have a severe degree of abnormal glucose tolerance and unquestionable diabetes. Of the 12 patients with adenomatous hyperplasia, two-thirds had a diabetic type of glucose tolerance curve. This is comparable to the group in whom unequivocal malignancy was present. A comparison of the control group and the group with endometrial carcinoma indicates that unquestionable diabetes is 3 times as common in patients with endometrial carcinoma as in those without this lesion. Evidence suggests that prolonged overactivity of the anterior pituitary gland may lead to these diverse constitutional manifestations in both groups of patients.

The Value of the Papanicolaou Smear in the Diagnosis of Carcinoma of the Uterine Cervix and of the Uterine Fundus. A. D. Anderson and G. G. King. Wisconsin M. J. 57:257-260 (July) 1958 [Madison].

The authors describe their experience with the Papanicolaou test in a small clinical practice, smears being taken from women seen in their offices. Since November, 1955, 1,043 Papanicolaou smears have been studied. Some of the late tests have been repetitious of earlier ones. The authors are of the opinion that the Papanicolaou smear test should be repeated at least once a year. Patients were instructed not to douche and not to use contraceptive jellies during the 2 days preceding the test. The aspirator present in all Papanicolaou kits was used first. It was inserted directly into the cervical os, and all free fluid and mucus was obtained. If insufficient material was present in the cervical os, the posterior cul-de-sac was also aspirated and smeared to make the first slide. The second slide was prepared by using half a tongue blade. The apex of the tongue blade was inserted into the cervical os; and, with the os as a pivot point, the tongue blade was scraped against the mucocutaneous junction of the cervix, hard enough in most cases to cause some bleeding. Immediately upon smearing, the slides were dropped into a bottle containing 95% alcohol.

Twenty-one malignant lesions of the cervix and 4 lesions of the fundus were diagnosed entirely by the Papanicolaou smear. One carcinoma of the fundus and 3 carcinomas of the cervix were diagnosed in the presence of negative Papanicolaou smears. These figures indicate an acuracy of approximately 86%. The Papanicolaou smear is a simple test and should be used routinely on all women. It is especially useful as a means of following patients who have received irradiation for cervical cancer, and it should be used during pregnancy. Patients with carcinoma of the cervix do not necessarily have symptoms or a visible lesion. Infections of the cervix and vagina with Trichomonas organisms should be treated vigorously and cleared up as quickly as possible. Early carcinoma of the cervix is a disease of young women and, when found at this early stage, can be treated surgically with an excellent chance of cure.

PEDIATRICS

The Determination of Genetic Sex in Children: A Critical Evaluation of the Reliability of Polymorphonuclear Leukocyte Morphology. K. H. Cooper and R. L. Cranny. A. M. A. J. Dis. Child. 96:40-42 (July) 1958 [Chicago].

An extranucleolar chromatin mass or "satellite" (also referred to as "drumstick") has been identified in the cells of the epidermis and in the polymorphonuclear leukocytes of human females. It serves as the basis for the determination of the genetic sex. The authors studied the morphology of the polymorphonuclear leukocytes of 65 patients of both sexes, ranging in age from 4 weeks to 75 years, in a blind fashion to evaluate critically this method of genetic sex determination. Five errors were made in the entire series, giving an over-all percentage of correct diagnosis of 92.3%. All the errors in diagnosis were made during the first half of the study. Three of the errors were believed to have been caused by poor technique in preparing slides, and, since later in the study no attempt was made to read poorly prepared films, it is probable that these 3 errors could have been avoided. The results of this study indicate that, under the proper circumstances, the morphology of the polymorphonuclear leukocyte is a reliable indicator of the genetic sex.

The Relationship of Little's Disease to Premature Birth. J. A. Churchill. A. M. A. J. Dis. Child. 96:32-39 (July) 1958 [Chicago].

"Little's disease" is the term applied to a morbid state established in infancy or prenatally and characterized by varying degrees of bilateral impairment in motility of the extremities and trunk. The Babinski sign and enhanced deep tendon reflexes differentiate this disorder from peripheral neuromuscular disorders and from purely dystonic and ataxic conditions. The term is generally used to denote those forms of cerebral palsy variously known as cerebral spastic paralysis, cerebral diplegia, congenital spastic paraplegia, spastic diplegia, and congenital quadriplegic spastic paralysis. The symptoms and signs of children afflicted with neurological disorders were correlated with gestational and parturitional factors known to be associated with high rates of infant mortality. The object of the study was to determine whether any one factor was more strongly associated with one type of neurological disorder than with another. This article deals particularly with the relationship of prematurity to different forms of cerebral palsy, mental deficiency, and epilepsy. There was a total of 562 patients, ranging in age from 2 to 20 years. All but a few came from homes in the region of Detroit and were from families with good standards of nutrition and health. Most of the data regarding physical findings and background history had been tabulated before the relationship of birth weigh to any particular set of neurological signs was suspected. The suspicion of a significant relationship between birth weight and Little's disease emerged from a preliminary inspection of the data.

The 562 cases were divided into 2 groups, depending on the presence or absence of the following findings: (1) bilateral Babinski sign; (2) hyperactive deep tendon reflexes; (3) increased (usually) or decreased muscular tonus; (4) reduced motility of extremities and trunk; and (5) onset of walking later than 14 months of age. The combination of these 5 manifestations, were referred to by the code symbol "D" (diplegia). Combinations of manifestations other than the 5 listed above were referred to by the code symbol "O" (other). There were assigned to the O group 483 patients, the birth weight being known in 454. There were 79 patients in the D group, the birth weight being known in 76. The mean birth weight of the 454 group O patients was 3,245 Gm. (7¼ lb.); that of the 76 group

D patients was 2,392 Gm. (5 lb.). The difference in birth weight between the 2 groups was highly significant. A study of the 76 patients coded as D, that is, those with diplegia or Little's disease, revealed that they could be divided into 2 groups, those with simple spastic diplegia, on the one hand, and those with complex diplegia, on the other. Patients with simple spastic diplegia exhibit symptoms and signs customarily interpreted in terms of damage to the corticospinal or pyramidal tracts, while those with complex diplegia exhibit, in addition, symptoms and signs usually interpreted in terms of dysfunction of other portions of the brain. Simple spastic diplegia has been found to correlate very significantly with low birth weight, to such an extent as to indicate a causal, though not necessarily a direct, relationship between prematurity and this disease. Complex diplegia, on the other hand, exhibits no significant correlation with low birth weight.

Long-Term Study of One Hundred Five Patients with Cystic Fibrosis: Studies Made Over a Five- to Fourteen-Year Period. H. Shwachman and L. L. Kulczycki. A. M. A. J. Dis. Child. 96:6-15 (July) 1958 [Chicago].

The survival beyond childhood of patients with cystic fibrosis is being noted with increasing frequency. The authors present observations on 105 patients observed over a period of 5 to 14 years after diagnosis. Duodenal intubation was performed in all the patients, and the fluid was examined for viscosity, trypsin, and pH in all the cases, for amylase and lipase values in the majority, and for chymotrypsin in a small number. In questionable cases, especially in those patients who were classified as having partial pancreatic insufficiency, intubations were repeated a number of times. The initial duodenal fluid sample showed complete absence of enzymes in 84 patients, whereas in 21 patients partial pancreatic insufficiency or normal enzyme activity was noted. In 5 of these latter patients progression to complete loss of pancreatic enzyme activity was subsequently noted. Beginning in July, 1954, the sweat test was performed, as devised by Shwachman, Dooley, and Higgins. Patients seen after August, 1956, were tested by the finger imprint method for chloride, and the test was strongly positive in each of 93 patients tested. The patients in this study were seen at regular 2-to-3-month intervals.

Prior to September, 1948, sulfonamides, penicillin, and streptomycin were the only therapeutic agents available. Penicillin and streptomycin were used primarily during acute exacerbations of pulmonary infections and were given intramuscularly or by aerosol. In a number of instances the sulfonamides were given "prophylactically" over prolonged periods. The beneficial effect of chlortetracycline (Aureomycin) was noted, and it has proved to be one of the most effective antibiotic agents in the treatment of cystic fibrosis. Oxytetracycline (Terramycin) was introduced in 1950 and has been equally effective. Chloramphenicol and erythromycin have been used liberally during the past 3 years, and novobiocin only sparingly during the past year. Neomycin administration by aerosol has been employed almost as frequently as penicillin and streptomycin aerosols during the last 2 years.

The patients were divided into 7 groups according to age at time of diagnosis. Ten patients had meconium ileus, and the cystic fibrosis of the pancreas was diagnosed within the first few days of life. In 21 patients diagnosis was made at less than 6 months of age; in 15, between 6 months and 1 year; in 18, between 1 and 2 years; in 32, between 2 and 8 years; and in 9, between 8 and 16 years. At the present time 41 patients are over 10 years of age. Ten of the 105 patients died during the period from July, 1956, to June 1, 1957, when this study was terminated. A system of clinical evaluation for cystic fibrosis is presented and is based on the following criteria: the general activity of the patient; the physical findings; the nutritional status; and the findings from the roentgenogram of the chest. Each of these 4 items is given equal weight in a scoring system in which 100 represents a perfect score. The present condition of the 95 patients in comparison with their original status is as follows: Forty-seven patients are now better, 27 are about the same, and 21 are worse. The authors emphasize the importance of a vigorous therapeutic program. It is hoped that the improved diagnostic tests now available will result in early diagnosis and prompt institution of effective therapeutic measures.

Primary Interstitial Myocarditis: Report of an Epidemic Outbreak. E. Freundlich, M. Berkowitz, A. Elkon and A. Wilder. A. M. A. J. Dis. Child. 96:43-50 (July) 1958 [Chicago].

Acute isolated interstitial myocarditis was first described by Fiedler in 1899. This type of interstitial myocarditis should be diagnosed only in the absence of any other pathological conditions that might be correlated with the myocardial involvement. The cause of this disease has never been clearly explained, and epidemic outbreaks have been reported only in recent years. This report is concerned with an outbreak of interstitial myocarditis in infants and children in the Haifa area, Israel. Between March, 1956, and December, 1957, 57 cases of interstitial myocarditis were observed, and 50 of the patients died. A few days before the onset of the acute heart failure a general malaise was noted, often accompanied by an upper respiratory tract infection. This prodromal stage usually lasted 1 to 3 days, but in several cases it could be traced back as far as 10 days and even more. Most of the patients had been examined at this stage, but except for a mild respiratory infection nothing abnormal was found.

The symptoms and signs of acute heart failure appeared suddenly. The child became restless and dyspneic and rejected food. Physical examination revealed marked pallor of the face and cyanosis of the lips. The breathing was labored, with a retraction of the costal arch. The extremities were cold and livid. The liver was enlarged and palpable 5 to 8 cm. below the costal margin. The heart sounds were usually weak. The pulse rate was always over 150 per minute, often up to 200. Moist rales were heard on auscultation of the lungs. The electrocardiographic and x-ray findings were typical of acute heart failure. In spite of treatment with digitalis, cortisone or prednisone, mercurial diuretics, antibiotics, oxygen, chlorpromazine (Largactil), and gamma globulin, no improvement was observed. The dyspnea was progressive, and the general condition deteriorated. The child became comatose and died usually in less than 24 hours after the first signs of the acute heart failure. The postmortem examination showed a dilated heart with interstitial infiltration with small lymphocyte-like cells.

Seven children in this series recovered and survived; 5 children recovered from the acute heart failure but developed another attack. Virological studies were performed in nearly half of the cases. In 1 single case a virus was grown on monkey-kidney-tissue culture from the heart muscle but not from other organs. The epidemiologic pattern, the geographical and chronological distribution of the cases, and the age incidence suggest an epidemic outbreak of primary interstitial myocarditis.

Acute Benign Pericarditis in Childhood. G. Bono and P. Garofalo. Minerva pediat. 10:366-376 (April 7) 1958 (In Italian) [Turin, Italy].

Acute benign pericarditis in childhood is a rare clinical entity; only 19 instances have been recorded in the literature. The authors report a boy, 8½ years of age, who was hospitalized because of a temperature of 38.3 C (100.9 F), precordial pain radiating toward the epigastrium and left shoulder, dyspnea, and considerable pericardial effusion. The condition was diagnosed as acute benign pericarditis, because there was no evidence of a rheumatic or a tuberculous infection or of a septicopyemic state. Treatment with digitalis was instituted, which promptly improved the cardiac function. Administration of large daily doses of penicillin for a period of 1 month and of sodium salicylate for 1½ months did not affect appreciably the course of the disease. Prednisone in a daily dosage of 1 mg. per kilogram of body weight was given for the first 2 days. The dosage was halved during the following 8 days. Prednisone brought about sudden relief of subjective symptoms (remission of fever, disappearance of precordial pain) but did not affect the objective symptoms and the pericardial effusion. The cardiac shadow returned to almost normal limits after 3 weeks. The electrocardiographic pattern, erythrocyte sedimentation rate, and white blood cell count revealed normalcy after a month. The boy was discharged on the 45th hospital day in complete remission, and that state has persisted for 10 months. The etiological nature of acute benign pericarditis is still obscure, being perhaps of viral origin. There is no specific method of treatment; recovery is spontaneous and invariable.

Colisepis as Cause of Icterus Gravis Neonatorum. J. H. W. Pielage and Liem Khe Hoo. Maandschr. kindergeneesk. 26:172-177 (May) 1958 (In Dutch) [Leiden, The Netherlands].

Jaundice in the newborn infant may have various causes, such as severe hemolysis, inadequate bile flow, or parenchymatous liver disease. On the basis of a case history the authors emphasize the importance of a correct diagnosis. A 17-day-old infant was hospitalized on account of severe jaundice. Physical examination showed an enlarged liver. Urinalysis demonstrated infection of the urinary tract. The combination of jaundice and pyuria was suggestive of neonatal septicemia. Cultures from blood and urine demonstrated Escherichia coli. Later the child developed an abscess on its back, also caused by Esch. coli. The cerebrospinal fluid obtained by lumbar puncture proved to be sterile but showed an increased number of cells and elevated protein level. The infant was treated with chloramphenicol combined with streptomycin and made an uneventful recovery. Intravenous pyelography showed a minor congenital malformation of the right pelvis. The diagnosis of septicemia must be suspected in every infant that is not "doing well."

Creeping Eruption, Larva Migrans: A Case of Ancylostomiasis Braziliensis. W. van Zeben. Maandschr. kindergeneesk. 26:160-161 (May) 1958 (In Dutch) [Leiden, The Netherlands].

The author presents the case of a 4-year-old boy who had been repatriated from Indonesia. Two months previously, while still in Indonesia, the child had played in a sandbox, and since then he had had an eruption on the buttocks, which caused severe itching, particularly at night. Eosinophilia did not exist, but examination revealed several red papules, and extending outward from these were several reddish streaks, representing infiltrated intracutaneous cuniculi. Scabies was thought of but could not be verified. The diagnosis of larva migrans was made after consultation with a colleague experienced in tropical medicine. Ancylostoma braziliense de Faria is an intestinal parasite in dogs, cats, and other small animals, and in Sumatra and Java it has been found also in human subjects. It is assumed that the sandbox in which the boy played may have been contaminated by feces of infected animals. Treatment consisted of freezing the lesion for 1 minute with ethyl chloride. This resulted in complete cure.

THERAPEUTICS

Clinical and Biological Investigations on the New Antituberculosis Drugs (Pyrazinamide and Cycloserine). A. O. Zorini, G. Spina and G. E. De Simoni. Dis. Chest. 34:27-46 (July) 1958 [Chicago].

The authors describe their experiences with pyrazinamide and cycloserine at the Carlo Forlanini Institute in Rome. Up to the time when this report was prepared (December, 1956), 100 patients had been treated with pyrazinamide, but only the 30 patients who had received a complete course of the treatment (4 to 6 months) are reviewed. In 11 of these the pulmonary tuberculosis was moderately advanced, and in 19 it was chronic. All these patients had been treated before with other antibiotics and chemotherapeutic agents. Patients who had evidence of hepatic dysfunction were not treated with pyrazinamide. The daily dosage of the drug (divided into 5 fractional doses) was 2.5 Gm. This dosage was usually reached by the 4th day of treatment. During treatment roentgenographic and planigraphic tests were carried out routinely, together with laboratory studies on serum electrophoresis, phagocytic index, protein-bound iodine value, adrenal cortical function, behavior of specific proteases of defense in urine, plasma lipasic power, serum cholesterol and bilirubin levels, plasma fibrinogen value, and prothrombin time, the colloidal serolability tests, and the charge tests of liver funtion.

Pyrazinamide showed a favorable action on tubercular lesions in a limited number of patients and for a short duration not exceeding 35 to 40 days of therapy, after which toxic phenomena, particularly hepatic disturbances, were observed. The laboratory tests showed abnormal values. The authors feel that pyrazinamide should be utilized in the therapy of pulmonary tuberculosis only after the employment of more effective and less toxic agents; furthermore, the treatment period should not be too long (a maximum of 40-50 days), with the possibility of reinstating the administration in the interval of therapeutic regimens executed with other antituberculosis drugs. The authors have not had sufficient experience with pyrazinamide in recent pulmonary tuberculosis, but they do not believe it worthwhile to substitute pyrazinamide for combined therapy with streptomycin and isoniazid. The latter remain the principal drugs used in the treatment of incipient active post-primary tuberculosis.

The authors used cycloserine for a period of 8 months in 88 patients. Sixty patients were treated with cycloserine alone (50 received a dose of 1 Gm. daily, and 10 received 1.5 Gm. daily); 26 patients received cycloserine (in daily doses of 0.5 Gm.) together with 0.3 or 0.4 Gm. of isoniazid; the remaining 2 patients received streptomycin and p-aminosalicylic acid, respectively, in addition to cycloserine. Cycloserine induced in two-thirds of the patients an appreciable clinical improvement and significant modifications of the roentgenographic picture, such as cavity closure and regression of exudative and miliary foci in 36% of the patients. In about 40% of the subjects whose sputum had been initially positive for tubercle bacilli, the sputum became negative on both direct smear and culture. Toxic effects of cycloserine on the central nervous system were not frequent and did not usually interfere with the continuance of therapy. The laboratory tests generally revealed normal values even after the second and the third month of therapy, showing a behavior contrary to that after pyrazinamide therapy.

Clinical Observations on the Use of Mecamylamine in the Treatment of Arterial Hypertension. P. Lucchelli. Gazz. med. ital. 117:174-182 (May) 1958 (In Italian) [Turin, Italy].

Mecamylamine was administered orally to 29 hospitalized patients with arterial hypertension, 17 of whom had essential hypertension and 10 the arteriosclerotic and 2 the renal type of the disease. A single dose, varying between 2.5 and 10 mg., reduced the mean systolic blood pressure from 197.12 to 161.62 mm. Hg; it reduced the mean diastolic blood pressure from 114.76 to 95.08 mm. Hg. The highest hypotensive response was recorded 3 or 4 hours after administration of the drug. Blood pressure values started to increase 6 or 7 hours after the administration of the drug. The most frequent complaints were vertigo, weakness, and digestive disturbances.

Twenty-three of the 29 patients continued to take the drug for longer periods, 16 as outpatients. Hospitalized patients received mecamylamine in a daily dosage of from 10 to 50 mg. for a period of 5 to 35 days. The maintenance dose was reached when the diastolic pressure was 105 mm. Hg or less. The mean value of the systolic blood pressure decreased from 203 to 184 mm. Hg, and the mean value of the diastolic blood pressure from 113 to 104 mm. Hg. Three patients did not respond to the ganglionic blocking effect of the drug. The daily dosage of the drug in the outpatient group varied from 10 to 45 mg. and was administered for a period of 2 to 112 days. Slightly better results were obtained in hospitalized patients than in the outpatient group. Two patients in the outpatient group did not respond to the drug. An appreciable decrease in blood pressure was observed in about one-half of the patients composing the combined hospitalized and outpatient groups. The most frequent complaints were stypsis, nausea, vomiting, xerostomia, and postural hypotension. These side-effects were slightly milder than similar ones observed during the use of other ganglionic blocking agents.

Treatment of Experimental Toxoplasmosis in the Mouse with Spiramycin. J. P. Garin and D. E. Eyles. Presse méd. 66:957-958 (May 28) 1958 (In French) [Paris].

Toxoplasmosis in man may on rare occasions appear in such an acute form (septicemia associated with multiple localizations) that, unless treatment is started promptly, the patient's life may be endangered. The rarity of severe toxoplasmosis in man, however, and the fact that most of the acquired forms of the disease are characterized by spontaneous regression make it impossible to evaluate the effectiveness of a medicament in man. The authors, therefore, induced the disease in white mice which are easily contaminated by a known number of micro-organisms of an established strain. A fixed dose of the medicament can easily be administered subcutaneously once a day or oftener for a determined period. Thus, the experimental method can be standardized; the results of various workers can be compared; and the anatomic and serologic cures can easily be checked. Among all the antibiotics tested, spiramycin seemed to stand out; it is produced from Streptomyces ambofaciens and is well tolerated by mice. Experiments were carried out by two groups headed by one author in Lyons, France, and by the other in Memphis, Tenn. Mice weighing 20 to 25 Gm. were inoculated by the intraperitoneal route with 20,000 Toxoplasma organisms of Sabin's RH strain. A 1% solution of spiramycin in distilled water was administered subcutaneously in 1 or 2 injections daily, beginning within 1 hour after inoculation. Daily doses of 8 mg. per mouse (i.e., 320 to 400 mg. per kilogram of body weight in man), producing blood concentrations of from 7 to 10 mcg. per milliliter of spiramycin in the course of the first 2 hours, were the most effective. These doses must be given for at least 2 weeks. Almost 80% of the mice inoculated with fatal doses of Toxoplasma organisms in both series were cured by this treatment. Spiramycin may thus be added to the list of drugs which are active against experimental toxoplasmosis in mice, such as the pyrimidine derivatives of sulfonamides, parent sulfone compounds, and pyrimethamine.

Adaptation of these experimental findings to human toxoplasmosis requires consideration of the following points: The doses usually given by mouth in man do not produce more than 3 or 4 mcg. per milliliter of spiramycin in the blood; moreover, as it is eliminated within 6 to 8 hours, the drug must be given in from 3 to 6 divided doses every 24 hours. The dose required in man is at least 100 mg. per kilogram of body weight. This dose is well tolerated for several consecutive days. The only side-effects are transient episodes of diarrhea. Doses of this magnitude are indicated in human toxoplasmosis, however mild the disease. The treatment must be continued for at least 3 weeks, because the optimum time for the formation of antibodies is 6 weeks. The results of this investigation show that spiramycin is effective against toxoplasmosis and can be used to advantage in the treatment of toxoplasmosis in man, either alone or in combination with one of the other drugs—sulfonamides, sulfones, or pyrimethamine.

Clinical Trials with DBI, a New Nonsulfonylurea Oral Hypoglycemic Agent. L. P. Krall and R. Camerini-Davalos. A. M. A. Arch. Int. Med. 102:25-31 (July) 1958 [Chicago].

The orally administered hypoglycemia-inducing agents used so far have been sulfonylurea derivatives with blood-sugar-lowering ability in certain types of diabetes. Within the last year studies were started with a new group of compounds classified as formamidinyliminoureas. These drugs are biguanides. This report is a clinical evaluation of the effectiveness of N^1-β-phenethyl-formamidinyliminourea hydrochloride, referred to as DBI. One hundred twenty-one diabetic patients were observed for periods varying from 1 day to 6 months. They were hospitalized, were kept on a constant weighed diet, and were observed individually by 3 physicians. Patients previously receiving insulin had DBI substituted for the insulin. Newly discovered diabetic patients were treated with DBI immediately after the diagnosis had been established. One-third of the patients experienced side-effects involving the gastrointestinal tract. Of 104 patients who were observed for an adequate period, 90 (or 86%) experienced a blood-sugar-lowering effect, although in 19 (18%) treatment was discontinued because of side-effects. Although the primary object of the study was lowering of the blood sugar, "good" or "fair" control was achieved in 66 of the 88 patients evaluated in this manner. Sixty patients are still on maintenance therapy with DBI. Only 6 of these take supplemental insulin, and these take less than 50% of their previous daily dose. Frequent liver-function, blood, and other studies have shown no evidence of toxicity. There was an observable blood-sugar-lowering effect in every age group tested and in every type of patient, including juvenile diabetics, in this series. The new drug, despite its annoying side-effects, may prove useful in the future if no toxic effects are found.

Transfusion Reactions from Contaminated Blood: Their Recognition and Treatment. A. I. Braude. New England J. Med. 258:1289-1293 (June 26) 1958 [Boston].

The saprophytic bacteria that inhabit the premises where blood is collected, stored, or transfused sometimes enter the bottles through carelessness and contaminate the blood itself. If large numbers of these contaminants are present in the transfused blood, they may lead to reactions, the violence of which depends on the properties of the contaminants. Three groups of these contaminants are considered. The first group consists of gram-positive saprophytes, such as diphtheroids. The other 2 groups consist of gram-negative bacteria, namely, cold growers, including members of the genus Pseudomonas or the genus Achromobacter, and coliform organisms. The 3 symptoms that dominate the reaction after transfusion of blood contaminated with gram-negative bacilli are fever, hypotension, and pain. These symptoms may appear after a latent period of 30 minutes or more and result from the transfusion of as little as 50 cc. of blood. Signs of renal failure become prominent after the first 24 hours, when there is a rapid development of azotemia with acidosis. In a bacterial transfusion reaction, intravascular hemolysis does not characteristically occur, and the diagnosis is established by the finding of many gram-negative bacilli in the smear of blood remaining in the bottle. In addition to the blood in the bottle, positive cultures may be obtained from the blood of the patient if the organism is a coliform bacillus possessing invasive qualities and capable of survival in vivo at the temperature of the human body. Isolation of vast numbers of bacteria from the recipient's blood may disclose the existence of an overwhelming bacteremia. Unlike the violent reactions from blood containing gram-negative organisms, the reactions that follow transfusion of blood overgrown by gram-positive bacteria may be harmless. A number of benign febrile reactions undoubtedly result from blood heavily contaminated by diphtheroids and other nonpathogenic, gram-positive bacteria.

The crucial point in treatment is prompt recognition of the syndrome and immediate administration of a tetracycline antibiotic in an initial dose of 1 Gm. and an additional dose of 2 Gm. during the first 24 hours. At the same time continuous intravenous administration of levarterenol must be instituted, which may be required long after the bacteremia is over. Not all tetracycline antibiotics are effective against all gram-negative bacilli; therefore, additional antibiotics that may be effective against gram-negative bacteria, such as chloramphenicol, neomycin, streptomycin, and penicillin, should be used. Two procedures can be depended upon for preventing transfusion of grossly contaminated blood: (1) microscopic examination by direct smear of blood just before the transfusion is started; (2) routine use of a tetracycline antibiotic in concentrations of 20 mg. per liter. This procedure prevents large sublethal inoculums of either cold growers or warm growers from multiplying in human blood at both refrigerator or room temperature. Such minute quantities of a tetracycline antibiotic would be harmless to the recipient.

Prednisone in Rheumatoid Arthritis: Metabolic and Clinical Effects. L. E. Ward, H. F. Polley, M. H. Power and others. Ann. Rheumat. Dis. 17:145-159 (June) 1958 [London].

At the time when the antirheumatic potency of cortisone was first emphasized, the belief was expressed that analogues superior to cortisone would be discovered. Since then, at least 7 more cortisone-like steroids have been found useful clinically; these include hydrocortisone, 9-alpha-fluorohydrocortisone (Fludrocortisone), prednisone, prednisolone, a compound whose structure is 9-alpha-fluoro, delta 1-hydrocortisone, triamcinolone, and 6-methyl, delta 1-hydrocortisone. Each of these 8 compounds has distinctive characteristics. The authors studied the antirheumatic and other clinical effects of prednisone and prednisolone on many patients with rheumatoid arthritis. In 3 such cases they made special studies concerning the metabolic effects of prednisone, and in 2 cases they compared these effects with those of cortisone or hydrocortisone. The metabolic balances of sodium, chloride, potassium, total nitrogen, calcium, and inorganic phosphorus were studied. Observations were made on electrolytes, urea, uric acid, proteins, sugar, and various lipids in the blood and on the urinary excretion of corticosteroids, 17-ketosteroids, uric acid, and creatinine. Studies also were made of the erythrocyte sedimentation rate, glucose tolerance, basal metabolic rate, and blood pressure, and electrocardiograms and electroencephalograms were taken.

It was found that prednisone (or prednisolone), when given to patients with rheumatic arthritis, produces effects similar to those produced by cortisone or hydrocortisone with respect to antirheumatic action, influences on the metabolism of nitrogen, carbohydrate, and fat, suppression of pituitary-adrenocortical function, and influences on blood cells and the basal metabolic rate. However, 2 important differences are noteworthy: 1. Prednisone is at least 4 or 5 times as potent as cortisone or hydrocortisone, milligram for milligram, both in antirheumatic effects and in most of the metabolic effects studied to date, except those relating to electrolytes. 2. Prednisone has relatively less effect on the metabolism of electrolytes and hence produces less retention of sodium, chloride, and water and less excretion of potassium, in comparison with cortisone or hydrocortisone in equivalent antirheumatic doses. The clinical use of prednisone or prednisolone must be attended by the precautions previously established for the optimal use of cortisone or hydrocortisone, namely, careful selection of patients, proper medical supervision during treatment, individual dosage schedules to provide optimal antirheumatic effects without hypercortisonism, special precautions at times of increased stress, and appropriate supportive and supplementary therapy.

Injection Abscess Due to Candida Albicans: Two Cases. K. R. Eriksen, J. L. Hansen and A. Stenderup. Ugesk. læger 120:643-644 (May 15) 1958 (In Danish) [Copenhagen].

Two cases of abscess at the site of the injection caused by Candida albicans occurred in patients who had received large doses of antibiotics for a long time; 1 of the patients had also had repeated cortisone treatment. The patients were in poor general condition. Complicating infection with C. albicans can be expected in such patients.

Hinconstarch in the Treatment of Pulmonary Tuberculosis. V. C. Barry, N. C. Browne, M. L. Conalty and others. Am. Rev. Tuberc. 77:952-967 (June) 1958 [New York].

A preliminary account of a pilot investigation of Hinconstarch (a polymer from periodate oxidized potato starch by condensation with equimolar proportions of isoniazid and *p*-aminobenzalthiosemicarbazone) described the results obtained in 12 patients with pulmonary tuberculosis treated for 3 months. The present report deals with the results obtained in 52 patients with pulmonary tuberculosis due to isoniazid-susceptible organisms and treated for periods of 3 to 12 months. Moderate or marked roentgenographic improvement was observed in 65% of the patients at 3 months and in 80% at 6 months, with increasing percentages at longer intervals. Closure of all cavities was achieved without surgery in 55% of the patients during the period of the trial. Disappearance of tubercle bacilli from the sputum occurred in 85% of the 52 patients. The findings in 10 patients who harbored tubercle bacilli resistant to 1 to 25 mcg. of isoniazid or more per milliliter at the start of treatment are also reviewed. In 2 of the 10 patients bacteriological "conversion" was observed. The authors conclude that a daily dosage of 40 to 45 mg. per kilogram is an effective dose of hinconstarch which does not cause toxic symptoms. Doses substantially larger than this may result in gastrointestinal or renal toxicity.

Studies with Streptovaricin in the Tuberculous Guinea Pig. K. F. Stern, J. E. Gray and L. E. Rhuland. Am. Rev. Tuberc. 77:976-982 (June) 1958 [New York].

Earlier studies had indicated that streptovaricin protects mice infected with Mycobacterium tuberculosis var. hominis (H37Rv) or M. tuberculosis var. bovis. The work reported here is an investigation of the efficacy of streptovaricin in guinea pigs. Tuberculin-negative guinea pigs weighing 400 to 500 Gm. were used. The animals were inoculated subcutaneously over the sternum with 0.5 ml. of a culture of M. tuberculosis (H37Rv) containing 4.5×10^5 viable units per milliliter. At 21 days post infection these animals were divided into 9 groups of 4 guinea pigs each. Five of these groups received 100, 50, 25, 12.5, and 6.25 mg. of streptovaricin. The sixth group received 5 mg. of isoniazid, the seventh group 15 mg. of streptomycin sulfate, the eighth group a lactose placebo, while the ninth group received no treatment. Treatment was continued daily for 62 days. At the termination of the study, surviving guinea pigs were killed, and pathological examinations were made.

The data obtained made it apparent that streptovaricin was efficaceous in the control of experimental tuberculosis. In the 50-mg. group of guinea pigs, no progressive tubercular lesions were observed in the lymph nodes which drained the site of inoculation or the lungs, spleen, and liver. In 1 guinea pig of the 100-mg. group, tubercular lesions regarded as progressive were present in some of the lymph nodes which drained the site of infection. The site of inoculation was free of cutaneous ulcerations in all guinea pigs of both groups. The 25-mg. dose of streptovaricin was regarded as subeffective inasmuch as progressive lesions were found at the site of inoculation, lungs, and spleen. However, the average index of infection was considerably lower than that in the placebo control, indicating some effect on the infection. The authors emphasize that a 50-mg. dose of streptovaricin had a therapeutic effect comparable to that of 5 mg. of isoniazid or 15 mg. of streptomycin.

PATHOLOGY

Bronchogenic Carcinoma in Young Persons. W. J. Hanbury. Brit. J. Cancer 12:202-206 (June) 1958 [London].

The author presents 2 instances of bronchogenic carcinoma in children and a third in a young man. The first patient, a 12-year-old girl, was the subject of a recent surgical resection, while the cases of the other 2 patients were found in the museum of St. Bartholomew's Hospital in London. In the 12-year-old girl, who had been subjected to a left-sided pneumonectomy, metastases subsequently developed in the liver, and death occurred 9¼

nously to 15 patients with liver disease and to 5 persons with normal liver; ferrous ions in a dose of 10 mg. were given intravenously to 9 patients with liver disease and to 3 persons with normal liver. Maximum concentration values of copper in the bile were observed between 60 and 90 minutes after injection in persons of the control group but between 1 and 72 hours in the patients with chronic liver disease. Maximum values were considerably lower in the patients than in persons of the control group. Decrease in the initial values was reached within 2 or 3 hours in the control group, but it took longer in the patients. The intravenous administration of the ferrous solution to persons in this series produced results analogous to those obtained by the administration of copper. After the intravenous administration of the copper solution, the concentration of iron in the liver bile decreased gradually in the control group but less constantly and more irregularly in the patients. An analogous response was obtained for the concentration of copper in the liver bile after the intravenous administration of the ferrous solution.

PUBLIC HEALTH

Studies on Myocardial Infarction in Malmö 1935-1954: II. Infarction Rate by Occupational Group. G. Biorck, G. Blomqvist and J. Sievers. Acta med. scandinav. 161:21-32 (No. 1) 1958 (In English) [Stockholm].

The infarction rate by occupation is a controversial question in the recent literature dealing with the epidemiology of coronary heart disease. Rathe, Master and Jaffe, Jacobs and Moll consider the socioeconomic status of the patients equivocal with regard to the development of myocardial infarction, while British authors point to an occupational difference in the incidence of coronary heart disease. Ryle and Russel have shown that in the upper (1st) social groups in the British social classification 3 times as many men die of "angina pectoris" as in the lowest (5th) social group. Stamler reports that unskilled laborers in the lower income brackets seem to have a higher mortality from coronary heart disease than other men of the same age. The present study of the hospital material of myocardial infarctions in Malmö subdivided the material into 3 occupational groups (employers, clerks, and workers) which are defined by the [illegible] which data on the composition [illegible] in Malmö can be con[illegible] have been further classified [illegible] or nonactive. [illegible] of occupationally active men [illegible] in the material numbered 654. These are distributed according to 5-year periods as follows: 1935-1939, 73; 1940-1944, 105; 1945-1949, 212; and 1950-1954, 264. The frequency of primary myocardial infarction in men of various occupational groups, expressed as the number of myocardial infarctions per 1,000 inhabitants in various age groups within the respective occupational groups, is approximately equal in the various male groups during the first 3 5-year periods. The figures from the last 5-year period show that the total rate (within the whole group above 30 years) is significantly higher for employers than for clerks and workers. The differences between the various occupational groups for women are not considered significant. The infarction rate was higher among married than among single, widowed, and divorced persons, and the wives of employers may have a relatively higher infarction rate than the wives of clerks, while the wives of workers have a lower rate.

The Mobile Unit X-ray Survey in Cardiovascular Disease Detection: A Report of 129,894 70 mm. X-rays, 3,477 Referrals. M. Feig, D. C. Cameron and A. Jensen. Wisconsin M. J. 57:261-265 (July) 1958 [Madison].

This report deals with the cardiovascular findings from 70-mm. chest x-ray films taken on 129,894 persons during 1955 by the Wisconsin State Board of Health mobile x-ray units. It is hoped that this report will demonstrate the effectiveness of Wisconsin's mobile x-ray program in heart disease detection to the practicing physicians and to the local health agencies. The survey did not include children under the age of 15 years unless exposure to tuberculosis was known to have occurred. Films taken in mental institutions, homes for the aged, and general hospitals also were deleted from this study. The board of health encouraged industrial groups to participate in the screening program, for tuberculosis has had a relatively high incidence in males over 45 years of age.

On the basis of the 129,894 films taken, 3,477 referrals were made, and 1,904 cases of heart disease were confirmed—a detection rate of 14.6 cases per 1,000 x-ray films taken. The authors emphasize that the 70-mm. chest x-ray is a useful and effective mechanism for heart disease screening. They suggest that the addition of a screening test for hypertension to the 70-mm. x-ray program should be of considerable value in bringing many persons to early medical care, thereby prolonging life and lessening disability. An additional benefit to be gained from this testing is that it will permit a more accurate and realistic estimation of the prevalence of cardiovascular disease in the general population than is presently afforded by a mere tabulation of death rates.

months after the operation and 10 months after the onset of symptoms. The other patients were youths, aged 16 and 22 years respectively. The younger patient died 1 month after the operation (7 months after the onset of symptoms) with signs of spreading infection. Sectioning of the right lung showed a whitish neoplasm, measuring approximately 6 by 7 by 8 cm., situated around the hilus and extending widely to involve the paratracheal lymph nodes, the pericardium, and part of the wall of the left atrium. Microscopic examination of the tumor showed a poorly differentiated bronchogenic carcinoma of predominantly oat-cell type.

In the 22-year-old man the neck veins were very prominent, and there were physical signs of collapse and consolidation of the right lung. Cutaneous nodules were present over the lower part of the sternum and in the lower lumbar region; a histological section of the latter was reported as showing a malignant tumor composed of columnar epithelium having an alveolar arrangement in places. A chest x-ray showed displacement of the heart and trachea, suggesting massive collapse of the right lung. Deep x-ray therapy was given, but the patient had increasingly severe attacks of dyspnea and died 17 days after admission (9½ months after the onset of symptoms). A review of the literature on bronchogenic carcinoma in patients below the age of 21 years revealed 60 instances.

Investigation in the Pathogenesis of the Pulmonary Hyaline Membrane. C. Zunin and E. Bertolotti. Minerva pediat. 10:479-484 (April 28) 1958 (In Italian) [Turin, Italy].

Pulmonary hyaline membrane is the only, or the most significant, pathological finding at autopsy of some newborn infants who die shortly after delivery. Autopsy, which was performed by the authors on 54 newborn infants, revealed the presence of pulmonary hyaline membrane in 18. Fourteen newborn infants were prematurely born, and 4 were born at term. The anatomicopathological picture was that of anoxia of the newborn. There are 2 etiological theories with regard to pulmonary hyaline membrane: the exogenous theory, according to which the membrane is derived from the amniotic fluid or its components; the endogenous theory, which attributes it to a protein exudate within the lung of the newborn infant. The authors made a histochemical investigation of the pulmonary hyaline membrane experimentally reproduced in guinea pigs and of that of newborn infants. Experiments were carried out in 4 groups of the animals. Amniotic fluid was given by the intrathecal route to 1 group; hyaluronidase was administered to 2 groups by inhalation and by the intrathecal route respectively; and a combination of amniotic fluid and hyaluronidase was given by the intrathecal route to the 4th group. Lepene-Pickwort and Millon stains were postive and similar in the newborn infants and in the group of guinea pigs which received the combination of amniotic fluid and hyaluronidase. No histochemical evidence of pulmonary hyaline membrane was present in the other 3 groups of guinea pigs. The authors conclude that a composite exogenous-endogenous theory of the etiology of pulmonary hyaline membrane seems to be the most probable.

Bronchial Adenoma (Carcinoid Type) with Solitary Metastasis and Associated Functioning Carcinoid Syndrome. W. R. Stanford, J. E. Davis, J. U. Gunter and S. G. Hobart Jr. South. M. J. 51:449-454 (April) 1958 [Birmingham, Ala.].

This report is the first of a case of bronchial adenoma of the carcinoid type which seemingly metastasized to the liver as a functioning carcinoid producing the hyperserotonin syndrome. The primary tumors of the functioning carcinoids reported up to now have been located in the small intestine. The patient was a 42-year-old woman who was admitted to the Watts Hospital, Durham, N. C., for the first time in May, 1944, for a pelvic operation. She was admitted again in 1945 because of pain in the left side of the chest and cardiac irregularity. She had had hypertension upon the first admission in 1944. In 1949 the systolic pressure ranged from 175 to 200 mm. Hg and the diastolic from 100 to 130 mm. Hg. At this time an x-ray film showed a density in the left suprahilar area which was thought to be a metastatic or primary lesion of the lung. The left lung was removed early in 1950 at another hospital (Duke University), and pathological examination revealed a bronchial adenoma of carcinoid type. The patient recovered with little respiratory distress. When she was hospitalized again on May 1, 1956, she complained of attacks of burning, flushing, and redness of the face, hands, forearms, and upper chest; throbbing in the ears; nausea; puffiness of the eyes; and nervousness. (She had had 1 or 2 similar attacks prior to admission.) The redness faded in about 24 hours, and she was discharged. On June 9, 1956, the patient was readmitted in acute distress in a severe similar attack. Gastrointestinal symptoms were more marked in this attack, with nausea, vomiting and diarrhea. The possibility of pheochromocytoma was considered.

One of the authors suggested hyperserotonin episodes from a carcinoid tumor. Other consultants agreed with the diagnosis of carcinoid tumor with hypersensitivity to serotonin. On Aug. 17, 1956, the urine test for serotonin metabolite 5-HIAA was positive. Flushing episodes now occurred at the rate of 1 to 4 per week. During an exploratory laparotomy in September, 1956, a tumor was removed from the subhepatic area. A tongue-shaped portion of liver was attached on 1 side. The thin fibrous capsule enclosing the tumor contained compressed liver cells, demonstrating that the tumor was actually located within the liver. Histologically this liver tumor was almost identical with the bronchial adenoma of carcinoid type removed from this patient in 1950. The liver tumor formed serotonin. No primary carcinoid tumor was found in the gastrointestinal tract of this patient, except the growth in the liver. At the time when this report was written the patient felt better than she had in years, and she has been completely relieved of symptoms due to hyperserotonin production.

Pathogenesis of Cancer of the Lung. G. L. Feofilov. Khirurgiya 34:66-71 (No. 3) 1958 (In Russian) [Moscow].

The author reports a histological study of 20 lungs removed for cancer. The affected and the adjacent lobes were studied. In 9 cases the cancer developed on the basis of chronic inflammatory changes, while in 2 cases a primary form of cancer was diagnosed. Chronic inflammatory changes of the bronchial walls were revealed by biopsy during bronchoscopic examinations. Inflammatory changes of the lungs were found in case histories of 78 patients with cancer of the lung. The author concludes that chronic inflammatory disease of the lungs constitutes a predisposing factor to the development of cancer.

ANESTHESIA

Elective Cardiac Arrest Under Moderate Hypothermia. A. Riberi and H. B. Shumaker Jr. Ann. Surg. 148:21-31 (July) 1958 [Philadelphia].

Mongrel dogs were utilized to induce cardiac arrest in the moderately hypothermic animal. In a preliminary investigation a series of dogs were subjected to 10-and-15 minute periods of vena caval occlusion. All the 10 animals subjected to a 10-minute vena caval occlusion survived and when killed 11 to 37 days later showed no evidence of brain or spinal cord damage. Ventricular fibrillation did not occur, and the only difference noted between those animals and the 5 which underwent procaine blockade was the quicker return of normal pupillary size and the prompter general recovery in the procaine block animals. An additional 10 animals subjected to a 15-minute vena caval occlusion recovered and when killed 9 to 15 days later exhibited no brain or spinal cord damage, save for lethargy on the first postoperative day. There was a single instance of ventricular fibrillation in 1 of the second group of animals which underwent procaine blockade.

The use of sodium citrate for the induction of cardiac arrest was investigated. Electrical arrest occurred promptly in 11 of the 23 animals in which rapid clinical standstill was achieved. In 8 dogs electrical arrest occurred several minutes after clinical arrest, and in the remaining 4 animals complete arrest according to electrocardiographic tracings was never attained. In all instances a good sinus rhythm was restored, although 2 animals died of hemothorax after surgery. The use of potassium lactate was studied in 36 dogs. At the end of vena caval occlusion heparinized oxygenated blood was perfused into the proximal part of the aorta and coronaries, and upon the myocardium becoming pink the coronaries were perfused with 10% calcium gluconate, 1 cc. per kilogram, after which the perfusion with oxygenated blood was continued. In all instances save one, restoration of vigorous cardiac activity ensued within 1 or 2 minutes. The one instance of ventricular fibrillation that did occur in this group was abolished, and the sinus rhythm was established immediately upon restoration of coronary perfusion. The latter method is the more effective in bringing about clinical and electrical arrest, and the restoration of vigorous heart function is readily accomplished.

Rewarming Following Hypothermia of Two to Twelve Hours: II. Some Metabolic Effects. B. Fisher, E. J. Fedor and S. H. Lee. Ann. Surg. 148:32-43 (July) 1958 [Philadelphia].

Of the 31 animals used in this study, all the 2-hour, 4-hour, and 8-hour cooled dogs survived after rewarming, while 5 of the 9 which had been hypothermic for 12 hours died within the first 24 hours upon attaining the normothermic state. The hematocrit of animals cooled 2 and 4 hours showed a 16% mean increase; there was a 20% mean increase after 8 hours of hypothermia and a 24% increase after 12 hours. After rewarming there was a prompt return to the control hematocrit in 5 of the animals cooled 2 hours. After 12 hours of cooling at 29 C (84.2 F) plus 5 hours all the hematocrits had not returned to precooling levels, the readings remaining high especially in those animals that failed to survive. In all groups an increased glucose content of the blood was noted prior to rewarming. No significant difference in plasma specific gravity before rewarming from the precooling values was observed. Whole blood specific gravity increased significantly upon cooling in all but the 2-hour cooled animals in which it remained unchanged. Although the exact mechanism is still in doubt, the increased hematocrits have been ascribed to either capillary leakage or differential plasma trapping with a concomitant decrease in the circulating blood volume. After cooling no significant change in blood lactates occurred even after up to 8 hours of hypothermia. Animals in all groups demonstrated a significant decrease in blood pyruvates, thus effectively increasing the lactate/pyruvate ratio to twice the upper normal limits. Blood amino acids were unchanged by cooling and rewarming. No significant alterations of serum sodium, potassium, calcium, chloride, or phosphorous values were reported. From these findings there is nothing to suggest that hypothermia or rewarming after hypothermia of approximately 6 hours' duration is attendant with changes that would preclude seriously considering abandoning this modality for clinical use, provided that the dangers of fibrillation could be eliminated.

PHYSIOLOGY

Discussion of Certain Works Relating to the Physiopathology of Traumatic Shock. H. Laborit. Presse méd. 66:977-979 (May 31) 1958 (In French) [Paris].

Recent investigations into the mechanism of shock tend more and more to show that the dominant element in the causation of this syndrome is the stable vasomotor reaction (vasoconstriction) of the splanchnic region. This reaction is protective in its immediate effect, but it leads to grave disorders when unduly prolonged. Hepatic circulation diminishes at the start of aggression, and the utilization of oxygen by the liver is greatly reduced. The liver becomes anoxic and liberates ferritin, or vasodepressor material, and this, in turn, is the cause of the circulatory decompensation and vascular atony found in decompensated shock. Ferritin can thus be regarded as a link between the peripheral vasomotor reaction now generally accepted as responsible for shock, the hepatic anoxia to which it leads, and the arteriolar atony which is its consequence. Inhibition of the vasomotor reaction is beneficial, because it maintains normal hepatic circulation and so prevents the liberation of ferritin. It has been amply shown that experimental animals can be protected against various types of shock by pharmacological substances capable of inhibiting the autonomic system and preventing peripheral vasomotor reactions. Attempts to maintain the arterial pressure by perfusions of arterenol in an animal in shock, however, eventually fail, because the doses must be continually increased until at last the animal becomes insensitive to the drug and dies. Tests have shown that small vessels fail to react to epinephrine applied locally when the liquid under study contains ferritin. Special interest, therefore, attaches to the discovery of GD 131 [N-(2-chlorethyl) N-(cyclohexylmethyl)-ethylamine hydrochloride], which is nontoxic and has no adrenergic blocking action but which does exert a protective effect by inhibiting ferritin. This fact, if confirmed, would be important because it would seem to show that, without altering hepatic anoxia of circulatory origin, the cellular metabolism can be influenced directly so as to nullify one or more of the causes of generalized circulatory atony, one of which is apparently the activation of ferritin. This means that, without suppressing the vasomotor reaction to aggression and the localized hypoxia which is its direct result, it would be possible to suppress the generalized atony which is its indirect result.

Some of the details connected with the theories according to which ferritin plays a predominant part in the development of shock are still obscure. One of the points that require clarification is the difference between the pharmacologically induced absence of vasomotor reactivity, which has an undeniably prophylactic effect in shock, and the absence of vasomotor reactivity that characterizes decompensated shock. Why is one of these states protective, while the other is harmful? The author's explanation is that, despite their functionally similar aspect, the two states are actually different: the first, which is favorable, is a state of relaxation or rest of the smooth muscle cells of the vessels which prevents anoxia, whereas the second is a state in which these same contractile muscle cells are exhausted as a direct result of anoxia. The failure of epinephrine to affect the small vessels, which is characteristic of decompensated shock, could then be explained by a metabolic and functional disturbance of the smooth muscle cells of the vessels, as well as by the possible oxidation of epinephrine. Recent experiments carried out by the author in relation to exhaustion of the hypertensive effects of arterenol confirm this belief.

Biliary Excretion of Copper and Iron Before and After Intravenous Administration of the 2 Metals in Patients with Chronic Liver Disease. A. M. Bertolini, N. Massari and C. Guardamagna. Policlinico (sez. prat.) 65:283-297 (Feb. 24) 1958 (In Italian) [Rome].

The authors studied the biliary excretion of copper and of iron in 32 persons, 24 of whom had a chronic liver disease and 8 of whom constituted the control group. An impaired liver function was associated with a decreased concentration of copper and iron in liver bile only in the advanced stage of the disease. The authors thought that by injecting an isotonic solution of the 2 metals into the circulation the excretory malfunction of the liver could also be revealed in the initial stage of the disease when it is most needed. Consequently, cupric ions in a dose of 12 mg. were given intravenously to 15 patients with liver disease and to 5 persons with normal liver; ferrous ions in a dose of 10 mg. were given intravenously to 9 patients with liver disease and to 3 persons with normal liver. Maximum concentration values of copper in the bile were observed between 60 and 90 minutes after injection in persons of the control group but between 1 and 72 hours in the patients with chronic liver disease. Maximum values were considerably lower in the patients than in persons of the control group. Decrease in the initial values was reached within 2 or 3 hours in the control group, but it took longer in the patients. The intravenous administration of the ferrous solution to persons in this series produced results analogous to those obtained by the administration of copper. After the intravenous administration of the copper solution, the concentration of iron in the liver bile decreased gradually in the control group but less constantly and more irregularly in the patients. An analogous response was obtained for the concentration of copper in the liver bile after the intravenous administration of the ferrous solution.

PUBLIC HEALTH

Studies on Myocardial Infarction in Malmö 1935-1954: II. Infarction Rate by Occupational Group. G. Biorck, G. Blomqvist and J. Sievers. Acta med. scandinav. 161:21-32 (No. 1) 1958 (In English) [Stockholm].

The infarction rate by occupation is a controversial question in the recent literature dealing with the epidemiology of coronary heart disease. Rathe, Master and Jaffe, Jacobs and Moll consider the socioeconomic status of the patients equivocal with regard to the development of myocardial infarction, while British authors point to an occupational difference in the incidence of coronary heart disease. Ryle and Russel have shown that in the upper (1st) social groups in the British social classification 3 times as many men die of "angina pectoris" as in the lowest (5th) social group. Stamler reports that unskilled laborers in the lower income brackets seem to have a higher mortality from coronary heart disease than other men of the same age. The present study of the hospital material of myocardial infarctions in Malmö subdivided the material into 3 occupational groups (employers, clerks, and workers) which are defined by the official statistics and for which data on the composition of the population in Malmö can be constructed. These patients have been further classified as occupationally active or nonactive.

The total number of occupationally active men with primary infarction in the material numbered 654. These are distributed according to 5-year periods as follows: 1935-1939, 73; 1940-1944, 105; 1945-1949, 212; and 1950-1954, 264. The frequency of primary myocardial infarction in men of various occupational groups, expressed as the number of myocardial infarctions per 1,000 inhabitants in various age groups within the respective occupational groups, is approximately equal in the various male groups during the first 3 5-year periods. The figures from the last 5-year period show that the total rate (within the whole group above 30 years) is significantly higher for employers than for clerks and workers. The differences between the various occupational groups for women are not considered significant. The infarction rate was higher among married than among single, widowed, and divorced persons, and the wives of employers may have a relatively higher infarction rate than the wives of clerks, while the wives of workers have a lower rate.

The Mobile Unit X-ray Survey in Cardiovascular Disease Detection: A Report of 129,894 70 mm. X-rays, 3,477 Referrals. M. Feig, D. C. Cameron and A. Jensen. Wisconsin M. J. 57:261-265 (July) 1958 [Madison].

This report deals with the cardiovascular findings from 70-mm. chest x-ray films taken on 129,894 persons during 1955 by the Wisconsin State Board of Health mobile x-ray units. It is hoped that this report will demonstrate the effectiveness of Wisconsin's mobile x-ray program in heart disease detection to the practicing physicians and to the local health agencies. The survey did not include children under the age of 15 years unless exposure to tuberculosis was known to have occurred. Films taken in mental institutions, homes for the aged, and general hospitals also were deleted from this study. The board of health encouraged industrial groups to participate in the screening program, for tuberculosis has had a relatively high incidence in males over 45 years of age.

On the basis of the 129,894 films taken, 3,477 referrals were made, and 1,904 cases of heart disease were confirmed—a detection rate of 14.6 cases per 1,000 x-ray films taken. The authors emphasize that the 70-mm. chest x-ray is a useful and effective mechanism for heart disease screening. They suggest that the addition of a screening test for hypertension to the 70-mm. x-ray program should be of considerable value in bringing many persons to early medical care, thereby prolonging life and lessening disability. An additional benefit to be gained from this testing is that it will permit a more accurate and realistic estimation of the prevalence of cardiovascular disease in the general population than is presently afforded by a mere tabulation of death rates.

QUESTIONS AND ANSWERS

BOOSTER DOSE OF TETANUS TOXOID

To the Editor:—*If one is injured a "short while" after completion of a series of tetanus toxoid inoculations or the receiving of his latest routine booster dose, is it necessary to give him another booster dose at the time of injury? What would the situation be one month, three months, six months, and one year after the last infection?*

Gerard Marder, M.D., Gastonia, N. C.

Answer.—Under the conditions delineated, a booster injection would not be mandatory even after a year, and possibly after several years. Certain pertinent principles are worthy of restatement (Spaeth, *Nebraska M. J.* 41:224, 1956): When measurable immunity diminishes or is lost completely, it can be restored by means of a small booster injection. Apparently there is no time limit on this recall capacity of the body. The available literature indicates that response to the booster dose can occur 10 or more years after the basic immunization. This recall response is rapid, appearing in about five days. It is higher, faster, and more prolonged than that noted with the basic injections. Although the booster dose can be small, it cannot be infinitesimal. For this reason, infection with the bacillus of tetanus does not elicit an adequate booster response; the amount of antigen is insufficient. Toxoid contains much more antigen in a nontoxic form. Likewise, although increasing amounts of tetanus toxoid elicit correspondingly greater responses, there seems to be no increase after 0.1 ml. is reached. Soluble forms of tetanus toxoid for the booster injection apparently give better responses than do depot toxoids. Nevertheless, depot toxoids can act as efficient booster stimuli. Individuals differ in their capacity to produce and retain antibodies in response to tetanus toxoid. Hence, statistical considerations cannot govern the individual case. Excluding booster injections during epidemics of poliomyelitis or during other acute illnesses, the contraindications to the small booster injections needed, i. e., 0.1 ml., are largely theoretical. Consequently, despite recommendations for booster doses every three years, it would seem safe and reasonable to maintain a perennial state of immunity by administering 0.1 ml., or even 0.05 ml. (with a tuberculin syringe), every two years or even once every year. Individualization must govern such a program. Although a very small number of individuals are "poor responders," with failure to produce antibodies protective against tetanus, toxoids of improved potency tend to reduce this number to an insignificant level.

RECURRENT CHRONIC FURUNCULOSIS

To the Editor:—*A patient, aged 54, has had repeated bouts of boils for the past three months which are resistant to any type of antibiotic or chemotherapy. This man has been studied for diabetes and other diseases which might make him more susceptible to infections, but he appears to have none of these. Culture of the organism shows it to be Staphylococcus pyogenes var. albus susceptible to nitrofurantoin as a first choice of medicament. What is the current status of autogenous vaccine in treatment of these resistant organisms? Would gamma globulin be of any value in such a case?* *M.D., Nebraska.*

Answer.—The treatment of recurrent chronic furunculosis is difficult. It is assumed from the question that these infections are not limited to any particular area of the body, such as the face, chest and back (acne), axillae and groins (hidradenitis suppurativa), or scalp (dissecting cellulitis), since these constitute special etiological and therapeutic problems. Often the new boils are produced by autoinoculation of pus through the hands or clothing. Therefore, sterilization of the surrounding skin is important. This can be accomplished best by the use of a rubbing alcohol sponge bath three times a day. There is no unanimity of opinion as to the value of autogenous vaccines. Most authorities feel that they are not of great value. Furthermore, it is doubtful if they are worth the expense of isolating the organism and preparing a special vaccine, since commercial stock agents, such as staphylococcus toxoid, seem to be as effective as the custom-made vaccines. It must be admitted, however, that most practitioners employ vaccines in such cases. At the 1958 Annual Meeting of the American Medical Association, Morginson reported that gamma globulin clinically repressed 94% of staphylococcic dermatoses but that relapses occurred in 83% within two to four months. Therefore, it is doubtful whether the use of this expensive medication would be indicated in a recurrent infection. Despite the gloomy picture painted by this answer, spontaneous recovery is to be expected

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

in such cases. This, of course, complicates the problem of evaluating therapeutic agents for recurrent furunculosis.

DESENSITIZATION

To the Editor:—*Please give information on the most up-to-date method of desensitization against horse serum. Administration of tetanus antitoxin in large doses, with an intradermal test done first, is being proposed. The manufacturers of the antitoxin give a method of desensitization based on an article by Mackenzie and Hanger (J. A. M. A. 94:260-265 [Jan. 25] 1930). Have there been any changes at this time in the recommendations on desensitization?*

M. A. Perlstein, M.D., Chicago.

Answer.—No perfect method of desensitization has been discovered. In the event that serious reactions are anticipated, one should consider the use of bovine antitoxin, after precautions have been taken to rule out allergy to this material. A comprehensive review of the prophylaxis of acute serum reactions is contained in an article by Spaeth (*Nebraska M. J.* 41:224, 1956).

RECURRENT NIGHT SWEATS

To the Editor:—*A patient, 41 years of age, complains of night sweats which start at 3:30 a. m. and last for about three and one-half hours. This has occurred regularly for the last eight months. On a few occasions when he has not had excessive perspiration, he has had a dull headache on the left side of his head. He states these headaches are very severe. In 1952, he had a similar occurrence which lasted only about three months. A complete physical examination shows this man to be in good health. Findings on chest x-rays were negative, as were those on an upper gastrointestinal series, taken because of burning and some distress in epigastrium. Blood cell count, urinalysis, and all other laboratory studies revealed normal findings. The thyroid gland appears to be normal, and his weight has remained constant. He feels well, except when he is having excessive perspiration, at which time he also has chills. His temperature taken during the night before and immediately after the attacks of excessive perspiration is normal. What is the possible diagnosis, and what treatment might be given?* *M.D., Michigan.*

Answer.—Excessively copious night sweats usually occur because of some infection which produces an intermittent fever, the fever and the sweats being associated. Tuberculosis is the classic culprit, and, despite the normal result of the examination so far, it would be well to do a tuberculin test. Other chronic infections should be sought. Occasionally, convalescence from a severe illness with prostration and debility leaves the person liable to excessive sweats not only at night but in the daytime. This is common after viral infections but rarely lasts more than a few days or weeks. An occasional patient with much anxiety may have attacks at night characterized by sweating and shivery feelings; these are usually without frank chills, often with tachycardia, and sometimes with palpitation or dyspnea. The sweating of thyrotoxicosis has no preponderant nocturnal emphasis. If thyroid disease can be excluded, it might be well to check into the seasonal occurrance of these attacks and find out whether the man uses too many blankets at night, sleeps in an overheated room, or has any findings suggestive of a neurosis.

ARTHRITIS OF THE SPINE

To the Editor:—*A patient, aged 52, has a mixed form of arthritis of the spine which could be described as rheumatoid arthritis (Bechterew's disease). It seems to show the typical changes in the cervical and dorsal region. There is definite osteoporosis of the entire spine and a loss of the sacroiliac joint space with fusion. This patient has some calcification of the ligaments in the lower spine. His brother also has this disease in its typical form. Is x-ray therapy considered beneficial when this condition has been present for a while? Is there any other treatment superior? What would be the treatment of choice? The patient's blood calcium level is 8.7 mg.%.*

M.D., Alabama.

Answer.—The collagen and arthritic diseases, of course, are not easily separated into definite diagnostic categories. A patient who has a generalized ankylosing arthritic process in his spine and sacroiliac joints goes through some acute phases when the process is painful. During these periods, x-ray therapy is beneficial to relieve some of the pain. No other treatment is of great benefit. However, conservative treatment to maintain the right posture of the spine, with a hard bed, physiotherapy, and a Taylor type of brace, are important.

PAIN IN THE TONGUE

To the Editor:—*A 59-year-old woman with multiple sclerosis complains of periodic bouts of neuralgic, knife-like pain in the right side of her tongue. Examination of the tongue, teeth, pharynx, larynx, and neck are unrevealing. She has taken various medicaments without appreciable relief. Please give suggestions for further therapy.*

Edward T. Carey, M.D., Clinton, Iowa.

Answer.—Knife-like pain in the tongue in multiple sclerosis is very unusual. Textbooks contain no discussion of this phenomenon, nor do the experts seem to have had any experience with it. Pain on the right side of the face is not unusual, but, limited to the tongue, it is exceptional. The only suggestion would be to attempt procaine alcohol block for the branch of the fifth (facial) nerve, which supplies the innervation to the tongue. Topical applications would be useless.

ELEVATED SERUM CHOLESTEROL LEVEL

To the Editor:—*A patient in his early 60's, who had on yearly examinations an only slightly elevated serum cholesterol level (240-270 mg.%) on an unrestricted, average diet, suffered a myocardial infarction about three months ago. He is now on a fat-restricted diet and receives papaverine hydrochloride, bishydroxycoumarin, and a combination of unsaturated fatty acids with vitamins* B_6 *and E. In spite of this, the serum cholesterol level stays considerably elevated; even when measured on different days, times, and hours it varies between 330 and 350 mg.%. Is there any possibility that the papaverine or bishydroxycoumarin may tend to raise or keep the serum cholesterol level high?*

W. Scheffler, M.D., Merchantville, N. Y.

Answer.—None of the drugs or other therapeutic measures mentioned should influence blood lipids except for the unsaturated fatty acids, whose influence, as reported in recent literature, has been to lower cholesterol levels in a high percentage of individuals with hyperlipemia. This patient should have adequate investigation to eliminate the possibility of myxedema or nephrotic syndrome with coincident hyperlipemia. If these can be eliminated, it would seem justified to discontinue medication other than the low fat diet and anticoagulant therapy and observe the effect on the serum cholesterol level.

UTILIZATION OF CALCIUM

To the Editor:—*Is the calcium in powdered milk as well utilized by the human body as the calcium in whole fresh milk? What is the relationship of calcium intake to the formation of teeth and to the prevention of caries?*

M.D., New York.

Answer.—From the nutritional standpoint, the calcium of powdered milk is as well utilized by the body as is that from fluid whole milk. It is present in the same form. The extent of the utilization of calcium will, of course, depend on other dietary factors, such as the amount of phosphorus, vitamin D, and the chemical forms of these elements in the diet. Phosphorus in the form of phytic acid, of course, interferes with the absorption of calcium. The calcification of the teeth is influenced by a number of factors. It is well known that vitamin D is essential to normal calcification. The parathyroid glands play a part in regulating the concentration of calcium ions in the blood plasma. According to the Council on Dental Therapeutics of the American Dental Association, "The available evidence indicates that if the calcium intake is adequate for general health, addition of calcium compounds to the diet does not serve to prevent dental diseases including caries or to medicate their effects." It should be remembered that enamel and dentine are practically completely calcified in an early age in life and experience only limited and varied calcification and replacement during the life of an individual. This proceeds at an extremely slow rate.

HERPETIC LESION AND MENSTRUATION

To the Editor:—*A question appeared in* The Journal *for June 14, 1958, page 925, regarding a patient who had herpetic lesions of the mouth prior to the menstrual period. A report of a similar case was published by Berger* (Ann. Int. Med. *42:205, 1955), and he established quite convincingly that his patient's ulcerative stomatitis was caused by endogenous progesterone, as suggested in the answer to the above question. Berger's patient was rendered free of symptoms by suppression of menstruation, and desensitization to progesterone was carried out by injection at weekly intervals. After resumption of menstruation, the patient remained free of symptoms for a year and remained so at the time of publication of Berger's report.*

CHOLESTEROL VALUES DURING PREGNANCY

To the Editor:—*This comment is made in reference to the question and answer on cholesterol values during pregnancy, which appeared in* The Journal *for July 19, 1958, page 1572. A recent study, performed by myself and associates* (Am. J. Obst. & Gynec., *to be published), on women during normal pregnancy revealed a steady rise in mean total cholesterol levels from 173 mg. per 100 cc. during the first trimester to 350 mg. per 100 cc. at the time of labor. Just prior to delivery, 51 of the 69 women tested had a total cholesterol level exceeding 300 mg. per 100 cc. and 17 had values in excess of 400 mg. per 100 cc. of blood. These values are higher than generally assumed. In addition, a study of 48 placental vein samples indicated that the newborn infants' total cholesterol levels averaged 117 mg. per 100 cc. The method of determination was that described by Schoenheimer and Sperry* (J. Biol. Chem. *106:745, 1934).*

Howard J. Wetstone, M.D.
Hartford Hospital
Hartford 15, Conn.

x-ray campaigns. However, PHS adds that "mass x-ray surveys still are a major case-finding activity, particularly in high prevalence areas and for groups of expected high incidence."

The PHS statement was issued as a follow-up on a recommendation made last year that in general tuberculin testing be substituted for x-rays. One of the reasons given was to reduce the risk of radiation exposure to large segments of the population through x-rays.

As to the status now, PHS reported:

"Most states have adopted the policy of tuberculin skin tests for the younger age groups, with chest x-rays for those who react positively. Some states are also eliminating high school and college x-ray surveys and replacing them with tuberculin testing programs, followed by x-rays for those who have positive reactions. There is also a trend toward the tuberculin test for such occupational groups as school employees and food handlers."

FOREIGN VIROLOGISTS ON POLIO STUDY IN U. S.

Eight virologists from eight nations have begun a nine weeks' poliomyelitis study course in the United States and Canada. They are studying poliomyelitis diagnostic techniques and vaccine production and control under World Health Organization fellowships.

The medical scientists come from the Soviet Union, Chile, Egypt, Nigeria, Poland, Lebanon, Austria, and French Equatorial Africa. Their itinerary includes the Communicable Disease Center at Atlanta, Ga., the Institute of Microbiology's Poliomyelitis Laboratory in Montreal, Canada, pharmaceutical companies in Detroit and Indianapolis, and, finally, the National Institutes of Health. They conclude with an evaluation session with the Pan-American Sanitary Bureau.

PERSONNEL

The new director of the Pan-American Sanitary Bureau starting next Feb. 1 will be Dr. Abraham Horwitz of Chile, who will succeed Dr. Fred L. Soper, now nearing the end of his 12th year as director. Dr. Horwitz is now assistant director of the National Health Service in Chile, on leave from the directorship of the School of Public Health, University of Chile. He served with PASB from 1950 to 1953 as chief of the professional education branch. Dr. Horwitz received his medical degree from the University of Chile in 1936 and a master's degree in public health from Johns Hopkins University. Dr. Soper has been named director emeritus of PASB.

Dr. Karl Habel, research scientist and authority on rabies, has been sent by the Pan-American Sanitary Bureau on a tour of five Latin-American governments where he will advise on rabies and other virus problems. He plans to visit Brazil, Argentina, Chile, Peru, and Panama. Dr. Habel is with the National Institutes of Health and is a member of the World Health Organization Expert Committee on Rabies.

CHEMOTHERAPY OF CHORIOCARCINOMA AND RELATED TROPHOBLASTIC TUMORS IN WOMEN

Roy Hertz, M.D., Delbert M. Bergenstal, M.D., Mortimer B. Lipsett, M.D., Edward B. Price, M.D.
and
Theodore F. Hilbish, M.D., Bethesda, Md.

Treatment with 4-amino-N^{10} methyl pteroylglutamic acid (Methotrexate) was carried out in 27 patients with tumors classified as trophoblastic. In each case the patient's urinary excretion of chorionic gonadotropic hormone served to indicate the nature and status of the tumor. In 19 cases the diagnosis was choriocarcinoma; in 3 it was chorioadenoma. The drug was given in five-day courses at a daily dose of 10 to 30 mg., usually administered intramuscularly but sometimes by continuous intravenous drip. In five patients a complete remission was observed; all hormonal, radiologic, and physical evidence of the tumor remained in abeyance for periods ranging from 8 to 29 months. Partial remissions were obtained in 7 and transient remissions in 10 cases. Six patients have died after the initial transient response. In five cases no remission was seen. The treatment involved a substantial hazard, for side-effects were often severe and not always reversible. In view of the striking nature of the results in some cases, the morbidity and mortality must be accepted as hazards of the treatment in its present form.

WE HAVE previously reported our initial experience in the treatment of choriocarcinoma and related trophoblastic tumors with folic acid antagonist, 4-amino-N^{10} methyl pteroylglutamic acid (Methotrexate).[1] We wish now to describe our further findings in 27 women whose therapeutic response to Methotrexate has been observed during the past two and one-half years.

Our rationale in applying antifolic acid therapy in cases of malignant trophoblastic disease of women stems from earlier laboratory and clinical studies. The high requirement for folic acid of the tissues of the female genital tract became apparent from experimental studies which showed that in the rat or monkey deficient in folic acid, the uterus is incapable of growth in response to administered estrogens.[2] Moreover, the high fetal requirement for folic acid was demonstrated in the rat by Nelson and Evans.[3] Indeed, Thiersch[4] reported the induction of therapeutic abortion in women by the administration of the folic acid antagonist, aminopterin sodium. In addition, the clinical phenomenon of the macrocytic anemia of pregnancy, responding as it does to folic acid therapy, also appeared to reflect an especially high requirement for folic acid in the rapidly growing fetal and maternal tissues of pregnant women.[5] Accordingly, we postulated that choriocarcinoma and related trophoblastic

tumors originating in the fetal chorion and initially involving the uterus might prove responsive to treatment with folic acid antagonists.

Materials and Methods

Patients were admitted to this study only when they presented unequivocal radiologic, hormonal, or clinical evidence of metastatic trophoblastic disease. This collective term refers to those patients in whom prior histological evidence of trophoblastic abnormality had been obtained and in whom subsequent clinical, hormonal, or radiologic evidence of disseminated disease was found. The criteria for the establishment of this diagnosis are presented for each case in the table. Hence these patients are referred to as having either choriocarcinoma or a related trophoblastic tumor.

The histological classification of the 27 cases of trophoblastic disease was choriocarcinoma, 19; chorioadenoma, 3; probable choriocarcinoma, 2; hydatidiform mole and necrotic uterine mass, 1; trophoblastic nodule of the cervix, 1; and inconclusive, 1. Therapy in the 27 patients resulted in remission with no evidence of residual disease in 5, remission with persistent disease in 11, initial remission and subsequent death in 6, and no initial response in 5. Four of the five in whom there was no initial response had received only one course of therapy. The criteria applied for pathology are essentially those described by Novak.[6] Problem cases were reviewed by several observers and a diagnostic consensus obtained.

The term hydatidiform mole is used when the intrauterine specimen is made up entirely of molar villi with or without associated blood clot, endometrial tissue, or decidua. The term chorioadenoma indicates that molar villi with associated trophoblast are observed within the myometrium or parametrium. The term choriocarcinoma is restricted to lesions characterized by extensive trophoblastic overgrowth with direct invasion of myometrium or parametrium or metastatic spread to extragenital sites. If the histological material suggests choriocarcinoma but is insufficient to meet the above cri-

Data on Twenty-seven Patients with

		Clinical Status in Admission			Histopathology	
Case No.	Age of Patient, Yr.	X-Ray Findings	Pelvic Examination	Other Findings	Specimens Available	Pathological Diagnosis
1	26	Extensive pulmonary metastases	Suprapubic mass, 11 cm.	Debility; anemia from massive uterine hemorrhage necessitating hysterectomy	Dilation and curettage; uterus	Choriocarcinoma
2	25	Pulmonary metastases progressing	Posthysterectomy	Pleuritic pain with right hemothorax	Uterus	Chorioadenoma destruens
3	25	Large single pulmonary metastasis	Posthysterectomy	Gastrointestinal bleeding; cerebral metastasis evidenced by diplopia; incoordination; abnormal electroencephalogram; retinal hemorrhage	Uterus; scalp nodule	Choriocarcinoma with scalp metastasis
4	18	Extensive progressive pulmonary metastases	Mass protruding from cervix; uterus 5 cm. above symphysis	Severe dyspnea; pleuritic pain; hyperpyrexia; vaginal bleeding	Biopsy of mass from cervix	Trophoblastic nodule*
5	21	Normal chest	Posthysterectomy	Had undergone pituitary stalk-section elsewhere; debilitated	Uterus	Choriocarcinoma
6	25	Extensive metastatic disease	Uterus enlarged three times; 3-by-4-cm. labial mass	Extreme dyspnea; fever; debility	Biopsy of left labial mass, uterus	Probable choriocarcinoma†; necrotic mass in uterus removed after therapy
7	30	Extensive metastatic disease; suprapubic soft tissue mass	Uterus enlarged three times normal size	Extreme dyspnea; fever; proved thyrotoxicosis	Dilation and curettage; uterus	Hydatid mole; necrotic mass in uterus removed after therapy
8	25	Normal chest	Vaginal metastases, 2 cm. by 1 cm.; posthysterectomy	Nausea; weight loss	Vaginal implants; dilation and curettage	Probable choriocarcinoma†
9	22	Normal chest; prior metastases regressed under nitrogen mustard therapy	Posthysterectomy	Asymptomatic; rising gonadotropin titer only evidence of disease	Uterus	Choriocarcinoma
10	27	Multiple pulmonary, metastases	Posthysterectomy	Weight loss; ambulatory	Dilation and curettage; uterus	Chorioadenoma destruens
11	22	Normal chest	Granulation tissue in operative field	Asymptomatic	Uterus	Choriocarcinoma(?)‡
12	22	Transient infiltrate in lower left lobe; no clear evidence of metastasis	Posthysterectomy	Asymptomatic	Dilation and curettage; uterus	Choriocarcinoma
13	23	Poorly defined multiple densities in both lungs; questionably metastatic	Posthysterectomy	Prior laminectomy for metastatic compression of spinal cord; residual neuropathy both lower extremities	Dilation and curettage; uterus	Choriocarcinoma
14	31	Diffuse nodular infiltration both lungs	Bleeding vaginal implant, 2 cm.	Vaginal hemorrhage; hemoptysis	Uterus	Choriocarcinoma

† Material suggestive but not conclusively diagnostic of choriocarcinoma.

teria, the diagnosis is listed as probable choriocarcinoma. Accordingly, nodules of trophoblastic tissue recovered from vagina or cervix are not considered sufficient basis for an unequivocal histological diagnosis of choriocarcinoma. It should be emphasized, however, that, notwithstanding these histopathological criteria, all the patients reported here presented clinical or hormonal evidence of disseminated disease at the time therapy was undertaken.

These tumors regularly provide a unique quantitative biological indicator of their extent and progression in terms of the patient's urinary excretion of chorionic gonadotropic hormone.[7] We have relied upon the hormonal titer as a major guide in clinical evaluation and therapy. These values are expressed as mouse uterine units excreted per 24 hours. The determinations were made at least once weekly by a modification of the method of Klinefelter and associates.[8] The urine specimens were quantitatively collected and were refrigerated immediately after voiding. A urinary value of 200 mouse units per 24 hours or less is normal in our laboratory for previously oophorectomized women. In those patients in whom such normal urinary titers had been obtained, a further check for absence of chorionic gonadotropic hormone was made in the serum, according to a modification of the method of Delfs.[9]

Metastatic Trophoblastic Disease

Methotrexate Treatment				Gonadotropin Titers				
Courses, No.	Duration of Therapy, Days	Total Dose, Mg.	Duration of Remission, Mo.	Before Treatment	In Remission	Most Recent	Current Clinical Status	Classification of Therapeutic Response
7	180	800	26	1,500,000	50	50	Completely rehabilitated	Remission with no evidence of residual disease by x-ray, physical examination, and titer (cases 1 to 5)

1	5	125	8	50,000	100	100	Completely rehabilitated; maintained on cortisone and triiodothyronine	
15, 7	309, 150	1,875, 875	26	200,000	1,000	500	Asymptomatic; persistent gonadotropin titer responding to repeated therapy	Remission with persistent disease manifested only by gonadotropin titer (cases 6 to 12)
10, 3§	135, 39	1,150, 37.5	16	12,000,000	500	16,000	Asymptomatic; persistent gonadotropin titer responding to repeated therapy; euthyroid	
5 3§	51 42	625 187.5	8	200,000	1,000	1,000	Asymptomatic; persistent low titer; continues on intermittent therapy	
6	75	750	5	400,000	500	2,000	Asymptomatic; continues on intermittent therapy	
3	31	375	7	500,000	500	300	Asymptomatic; marginally elevated titer	
2§	18	112.5	2	2,000	300	300	Asymptomatic; marginally elevated titer	
6	131	800	5	2,000,000	1,000	2,000	Asymptomatic	
4§	65	250	2	1,100,000	4,000	4,000	Residual neuropathy	Remission with clinically demonstrable disease (cases 13 to 16)
8§	125	895	6	2,000,000	1,000	30,000	Residual pulmonary disease by x-ray; vaginal implant completely regressed; therapy continues	

‡ Subsequent review of additional material from hysterectomy specimen failed to show clear-cut myometrial invasion by trophoblast; hence histological diagnosis of choriocarcinoma is not conclusive. § Given intravenously. ‖ DON = 6-diazo-5-oxo-L-norleucine.

In addition, because of the great frequency of pulmonary metastases, we have used frequent x-ray examinations in the therapeutic evaluation. Pelvic manifestations of disease, including uterine enlargement, vaginal implants, uterine bleeding, and secondary obstructive effects on the urinary tract, were also carefully followed. Central nervous system metastases also provided readily assessable neurological criteria of involvement and response to therapy.

All patients were treated according to a specially devised, intensive regimen with Methotrexate. The drug was given in five-day courses at a daily dose of 10 to 30 mg., usually administered intramuscularly and in some instances by continuous intravenous drip. The patient's toxicity, especially in terms of stomatitis, intestinal irritation, and cutaneous reactions was constantly appraised. The fluid intake and output were determined each day. Adequate fluid balance was maintained by the use of semiliquid or liquid diets or with parenteral fluids. Stomatitis was treated by frequent oral lavage with diluted viscous lidocaine (Xylocaine) hydrochloride.

The patient's hepatic and renal status was determined by appropriate laboratory and clinical studies both before and at frequent intervals during Methotrexate therapy. Also, at one-to-three-day intervals the leukocyte, erythrocyte, platelet, and reticulocyte counts were determined. Successive courses of therapy were not begun until all prior signs of toxicity had subsided. Continuous follow-up has been maintained in all surviving patients, and autopsy was performed on all those who died.

Results

The initial clinical status of each of the 27 patients is briefly sketched in the table. All but five were gravely ill on admission. Their most immediate clinical problems were respiratory distress due to extensive pulmonary disease and protracted vaginal bleeding. Pulmonary metastases were radiologically demonstrable in 22 patients. Cerebral involvement with evidence of increased intracranial pressure and other neurological manifestations were the presenting clinical features in five patients. Three patients were completely asymptomatic and lacked clinical or radiologic evidence of disease. They were, however, admitted for therapy because of persistence of an elevated hormone titer after prior hysterectomy.

Data on Twenty-seven Patients with

Case No.	Age of Patient, Yr.	Clinical Status in Admission			Histopathology	
		X-Ray Findings	Pelvic Examination	Other Findings	Specimens Available	Pathological Diagnosis
15	26	Multiple large pulmonary metastases	Fundus 3 cm. above pubis	Left hemiparesis following temporoparietal resection for metastasis; papilledema; debility	Cerebral metastasis	Choriocarcinoma
16	25	Multiple pulmonary metastases	Posthysterectomy	Marked dyspnea	Uterus	Choriocarcinoma
17	39	Numerous metastases	Hegar's sign; normal fundus	Metastatic nodule, 3 cm., in left breast; prior lobectomy	Metastases from lung, breast, and brain	Choriocarcinoma
18	28	Extensive pulmonary metastases	Left adnexal mass	Vaginal bleeding; pleuritic pain	Dilation and curettage; autopsy	Choriocarcinoma *
19	36	Extensive pulmonary metastases	Posthysterectomy	Cerebral metastasis; abnormal electroencephalogram	Uterus and autopsy	Choriocarcinoma
20	23	Extensive pulmonary metastases	Irregular nodular fundus	Blurred vision; headache; papilledema; Babinski's sign; abnormal electroencephalogram	Dilation and curettage; autopsy	Choriocarcinoma
21	22	Extensive pulmonary metastases	Suprapubic mass, 6 cm.	Fever; severe sweating	Dilation and curettage; autopsy	Choriocarcinoma
22	38	Normal chest; hydronephrosis and hydroureter	Posthysterectomy; hard pelvic mass	Right urinary tract obstruction requiring nephrostomy	Dilation and curettage; uterus; autopsy	Chorioadenoma destruens
23	30	Huge pulmonary metastases	Many large vaginal implants	Metastatic mass in left calf; herpes zoster; severe dyspnea	Uterus; autopsy	Choriocarcinoma
24	47	Small nodular metastases	Mass in right vaginal formix; vaginal hemorrhage	Hydronephrosis and hydroureter requiring right nephrostomy	Autopsy	Choriocarcinoma
25	48	No apparent metastases	Posthysterectomy	Coma, icterus	Autopsy	Choriocarcinoma
26	51	Extensive pulmonary metastases	Vaginal implants	Marked dyspnea	Autopsy	Choriocarcinoma
27	31	Small pulmonary metastases	Posthysterectomy	Icterus; papilledema; postcraniotomy	Brain metastasis; autopsy	Choriocarcinoma

* Nodule composed of syncytiotrophoblastic cells and necrotic tissue.

† Material suggestive but not conclusively diagnostic of choriocarcinoma.

The number of five-day courses given to any one patient varied from 1 to 22. The average number of courses given those patients who received more than one course was six. The average period of time occupied by a given five-day course was 12 days, and the average total dose of Methotrexate per patient was 620 mg.

Complete Remission.—The responses of these 27 patients assumed several distinct patterns (see table). In five patients we have observed a complete remission with no hormonal, radiologic, or physical evidence of recurrence for periods now ranging from 8 to 29 months. Three of the patients in this group had, by histopathological criteria, unequivocal choriocarcinoma; one had chorioadenoma; and in one, the only tissue specimen available was a biopsy of a fungating mass of necrotic tissue containing a few syncytiotrophoblastic cells exuding from the cervix. However, this patient and three others in this group of five presented pulmonary metastases by x-ray on admission, and four had undergone hysterectomy. Two of these cases are briefly summarized below.

CASE 3.—A 25-year-old woman, para 1, gravida 2, had undergone hysterectomy nine months prior to admission, and the surgical specimen revealed choriocarcinoma. She was then symptom-free until three weeks prior to admission when, because of severe abdominal pain, she underwent resection of a benign cyst of the left ovary. A few days later, a bleeding scalp nodule was resected and proved to be metastatic choriocarcinoma. Two weeks prior to admission the patient developed nausea and vomiting, severe frontal headache, and blurring of vision. On admission, intracranial metastasis was manifested by peripapillary hemorrhage in

1	4	100	...	500,000	...	500,000	Died on ninth hospital day	

‡ Subsequent review of additional material from hysterectomy specimen failed to show clear-cut myometrial invasion by trophoblast; hence, histological diagnosis of choriocarcinoma is not conclusive. § Given intravenously. ‖ DON = 6-diazo-5-oxo-L-norleucine.

the left fundus, diplopia, and left strabismus, and there was a distinctly abnormal electroencephalogram compatible with a right parietal or possibly posterior fossa lesion. She passed numerous large tarry stools and required multiple transfusions.

Over a 40-day period she was given four courses of Methotrexate, each consisting of 25 mg. given daily and intramuscularly for five days. Varying degrees of oral and hematological toxicity were encountered with each course. The fourth course induced extremely severe stomatitis with extensive buccal ulceration. The gastrointestinal bleeding subsided during treatment, and there was prompt reversal of all neurological abnormalities. Electroencephalograms taken before the third course and repeated 20 days later were both normal. As shown in figure 1, the hormone titer fell from 1,500,000 units to less than 100 units, and the pulmonary lesion promptly regressed. Since the patient's discharge, her chest x-rays remain negative, her hormonal titer is within normal limits, and no physical or subjective manifestations of disease are detectable. Her remission has now persisted for 11 months.

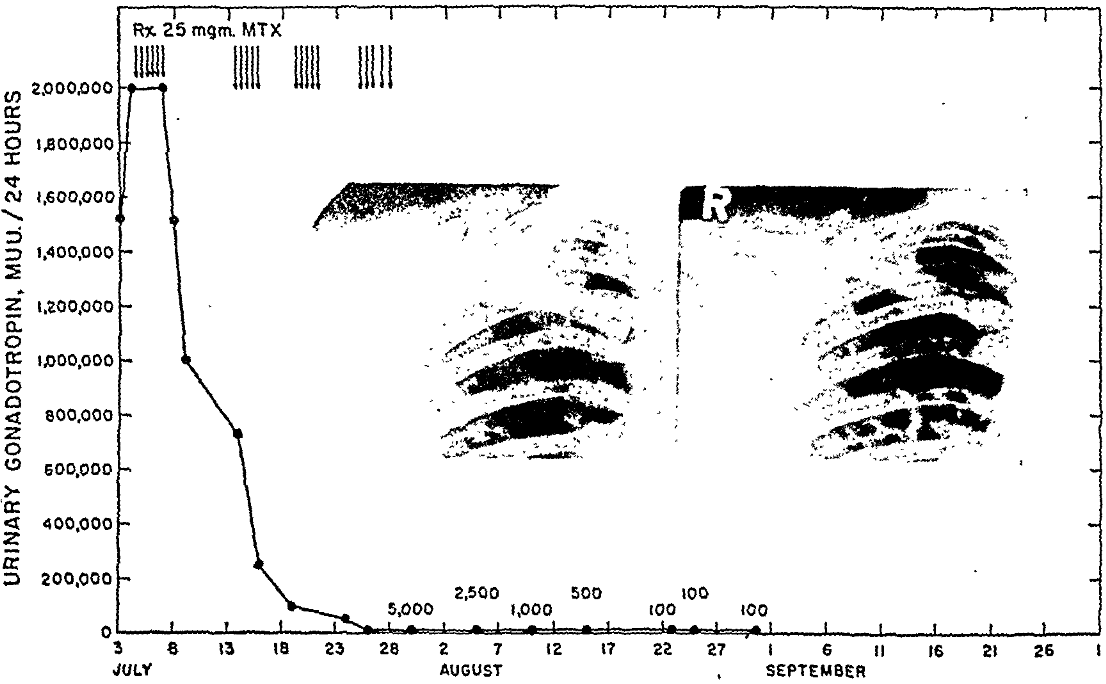

Fig. 1 (case 3).—Radiologic and hormonal response in patient with choriocarcinoma. Vertical arrows indicate courses of Methotrexate.

Case 4.—A 18-year-old woman, gravida 1, para 0, had passed a mole two and one-half months prior to admission. She then had intermittent vaginal bleeding and numerous severe episodes of high fever for which she received penicillin and streptomycin. One and one-half months prior to her admission, metastatic lung lesions were demonstrated, and results of the Aschheim-Zondek test became strongly positive. The week before admission she was given numerous blood transfusions and developed severe left lower quadrant pain with recurrent high fever. On the patient's admission, the uterus was enlarged three times and extremely tender. A 4-cm. ovoid, red, fungating mass presented from the os cervix. Biopsy proved this to consist of syncytiotrophoblastic cells associated with considerable hemorrhage and necrosis. She required numerous transfusions and continuous oxygen therapy.

Over the ensuing 53 days she was given four courses of Methotrexate intramuscularly, with each course consisting of 25 mg. daily for five days. After the first course little toxicity was encountered. However, the patient experienced severe oral toxicity and marrow depression after the last three courses. During the first two weeks of treatment she continued to be gravely ill with extreme dyspnea, pleuritic pain, hemoptysis, and lower abdominal pain with tenderness. Ten days later distinct improvement was manifest in terms of radiologically demonstrable regression of the pulmonary metastases (fig. 2), marked improvement in respiratory function, visible regression of the cervical mass to a diameter of 2 mm., regression of the uterus to half its previous size, and loss of lower abdominal pain and tenderness. The gonadotropin titer continued to fall to within normal limits (fig. 2), and the chest x-ray reflected continuing improvement during ensuing courses of therapy. Since discharge, she has presented no hormonal, radiologic, or clinical manifestation of recurrent disease. Her remission has now persisted for the past 10 months. (Duration of remission is calculated throughout this report from the time of initial favorable response to therapy as manifested by initial reduction in gonadotropin titer or objective regression of metastases.)

Partial Remission.—Seven patients have presented a less complete response to therapy in that they continue to exhibit unequivocal hormonal evidence of persistent disease. However, each has shown a striking reduction in titer, and three have shown complete regression of pulmonary metastases. We can find no radiologic or physical evidence of active disease in any of these seven patients, but their hormone titers, although very much lower than before therapy, clearly reflect latent disease. Three of these patients have been treated on successive occasions whenever their titers increased. The hormonal and radiologic responses of one of these patients (case 7) who has been effectively treated on three occasions during the past 16 months are shown in figures 3 and 4. The x-rays of a patient (case 6) who has been similarly treated during the past 26 months are shown in figure 5.

Transient Remission.—Ten patients have initially experienced a substantial but transient remission of three to six months' duration and have subsequently developed apparent refractoriness to Methotrexate therapy. All of these patients showed a marked depression of hormone titer during remission; six exhibited regression of pulmonary metastases, and three showed objective improvement in neurological status. Notwithstanding additional Methotrexate therapy and, in four instances, brief courses of mechlorethamine hydrochloride (nitrogen mustard) and 6-diazo-5-oxo-L-norleucine, all of these patients have shown progression of disease, and six have died. A marked rise in gonadotropin titer was observed in every patient as the disease became exacerbated (see table). One patient (case 16) still has pulmonary disease, but her titer is decreasing as she continues on Methotrexate therapy.

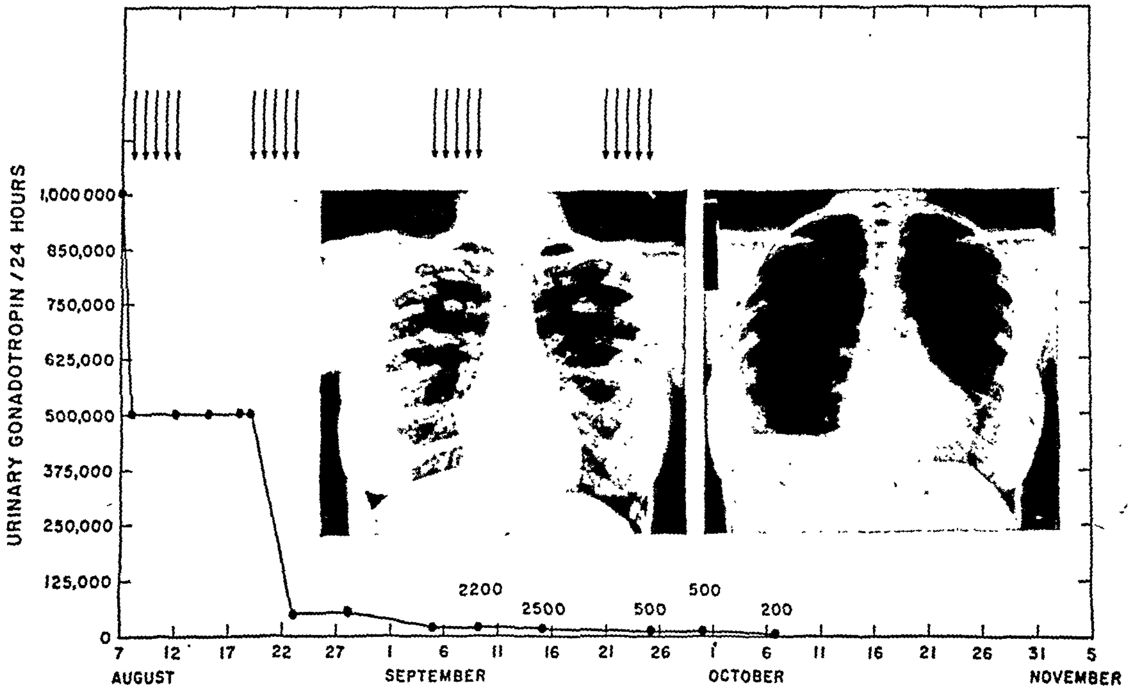

Fig. 2 (case 4).—Radiologic and hormonal response in patient with trophoblastic nodule. Vertical arrows indicate courses of Methotrexate.

Among the six patients who have died after initial response, one (case 22) died from drug toxicity. She had previously shown numerous drug allergies. She had tolerated four preceding courses of Methotrexate with moderate stomatitis and with evidence of marrow depression but had exhibited a rather severe drug rash with each course. After the fifth course she developed jaundice, enteritis, a profound leukopenia, and died. Autopsy revealed an acute toxic hepatitis, extensive gastrointestinal ulceration, and extreme marrow destruction. Two other patients who were profoundly debilitated on admission died after an initial course of Methotrexate. Whereas the lethal outcome in these two cases was not clearly attributable to drug toxicity, the autopsy findings indicate that this was probably a contributing factor.

These instances of probable lethal toxicity stand in direct contrast with the reversible toxicity encountered during the Methotrexate regimen used in these studies. We have now administered 220 individual courses of therapy to these 27 patients and to 13 additional patients with other types of tumors. Hence, one may conclude that such intensive Methotrexate therapy is clinically feasible although certainly not without substantial hazard.

Comment

The most frequent manifestations of reversible toxicity are stomatitis, marrow depression, drug rash, anorexia, and nausea with occasional emesis and diarrhea. These manifestations vary widely in intensity from patient to patient and even in the same patient from one course to the next. Accordingly, constant medical surveillance of the patient's status is mandatory, and appropriate supportive medical and nursing care should be readily available. Since Methotrexate is largely excreted in the urine, the maintenance of adequate fluid intake and output is of prime importance. Preexisting hepatic or renal dysfunction should serve as contraindication to such intensive therapy. This regimen should also not be applied in the presence of residual marrow suppression after radiation or other forms of chemotherapy. Since the maximum clinical toxicity is most frequently encountered from four to seven days after the completion of a five-day course, it is most often not feasible to control these manifestations by drug withdrawal. Moreover, it is imperative to delay further therapy until the signs of prior toxicity have subsided.

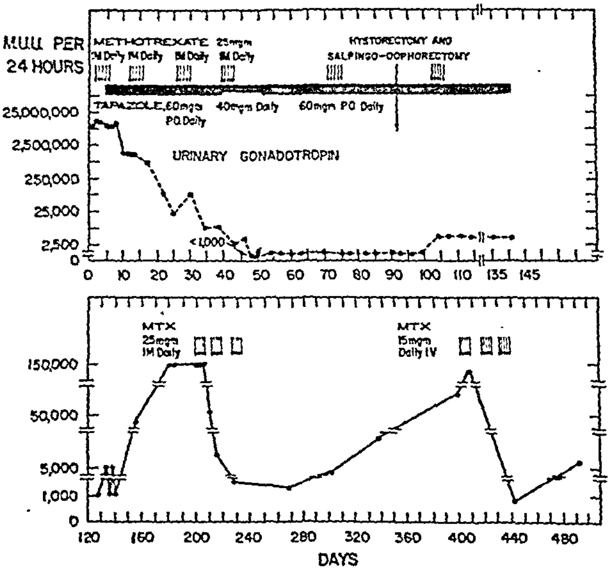

Fig. 3 (case 7).—Repeated hormonal response of patient to intermittent Methotrexate therapy during 16 months. Vertical arrows indicate courses of Methotrexate.

In the section on "Materials and Methods" the therapeutic results to date are summarized. If we exclude the four patients who received only one course of therapy just prior to death, it will be noted that 22 of the remaining 23 showed an initial substantial response to therapy, most notably in terms of suppression of hormone titer. These responses are graphically summarized in figure 6 and are detailed in the table. This reflects an almost uniform initial sensitivity of these trophoblastic tumors to Methotrexate and indicates the therapeutic potential of this regimen.

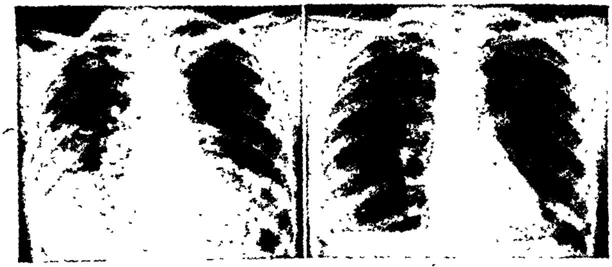

Fig. 4 (case 7).—Initial radiologic response in patient (*left*) on admission and (*right*) after five courses of Methotrexate in 75 days. Chest x-ray 16 months after start of therapy remained negative.

It is, however, much more difficult to assess the immediate relationship of the Methotrexate therapy to the total clinical course, particularly in those patients who thus far exhibit no residual evidence of disease. Subsidence of even metastatic trophoblastic disease without the specific therapy used by us is a well-documented phenomenon.[10] Moreover, a clinically benign course has been recorded in patients presenting unequivocal metastatic choriocarcinoma.[10] Conversely, the experience reported here and that of other observers includes fatal cases associated with lesions sometimes regarded as not unequivocally malignant.[10]

Because of the limited number of cases in which both clinical course and complete histological analysis are available, we have little statistical basis on which to differentiate the outcome in our cases from potentially spontaneous clinical events. However, the spontaneous occurrence of 5 complete remissions among 27 unselected cases of advanced, metastatic trophoblastic disease may be regarded as highly improbable, particularly since three of these five patients had unquestioned choriocarcinoma. Moreover, the unequivocal quantitative evidence of the extreme initial responsiveness of these tumors to Methotrexate would serve to support the interpretation of a cause and effect relationship between the benign course in these cases and the therapy applied.

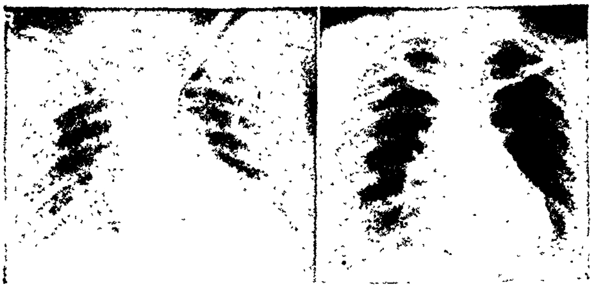

Fig. 5 (case 6).—Radiologic response in patient (*left*) on admission and (*right*) after six courses of Methotrexate in 125 days. Chest x-ray 26 months after start of therapy remained negative.

The problem of initial and acquired drug resistance is common to all forms of chemotherapy. In the present experience we have noted only one instance (case 23) of apparent initial drug resistance. This patient had had extensive radiation and several courses of nitrogen mustard therapy before she received Methotrexate, and this prior treatment may have been a factor in the failure of response to Methotrexate.

The acquired Methotrexate resistance among previously responsive patients has assumed a fixed pattern in most instances, since additional intensive Methotrexate therapy has usually proved totally ineffective. However, in three patients (cases 6, 7, and 8) some recovery of responsiveness has been noted after varied intervals off therapy (fig. 3). For this reason intermittent therapy aimed at maximally obtainable suppression of gonadotropin titer and therefore presumably of trophoblastic disease may ultimately provide the most prolonged periods of remission. In any case, it is too early to establish an optimum mode of management for these patients. Hence our further trials will have to remain largely exploratory.

Other forms of chemotherapy for malignant trophoblastic disease have been described. Thus, nitrogen mustard has been reported[11] to induce remissions associated with regression of pulmonary metastases and suppression of gonadotropin titer. Also, Li and Magill[12] have presented data indicating significant response to 6-diazo-5-oxo-L-norleucine. One of our patients (case 9) had been treated with nitrogen mustard with unequivocal regression of pulmonary metastases one year before admission to our service. Accordingly we have attempted mustard therapy and only brief courses of therapy with 6-diazo-5-oxo-L-norleucine in four of our Methotrexate-resistant patients with advancing disease. In this advanced clinical phase we observed no effect in any of these four patients from either form of therapy. These limited observations suggest a degree of crossover in tumor resistance to the several forms of chemotherapy applied.

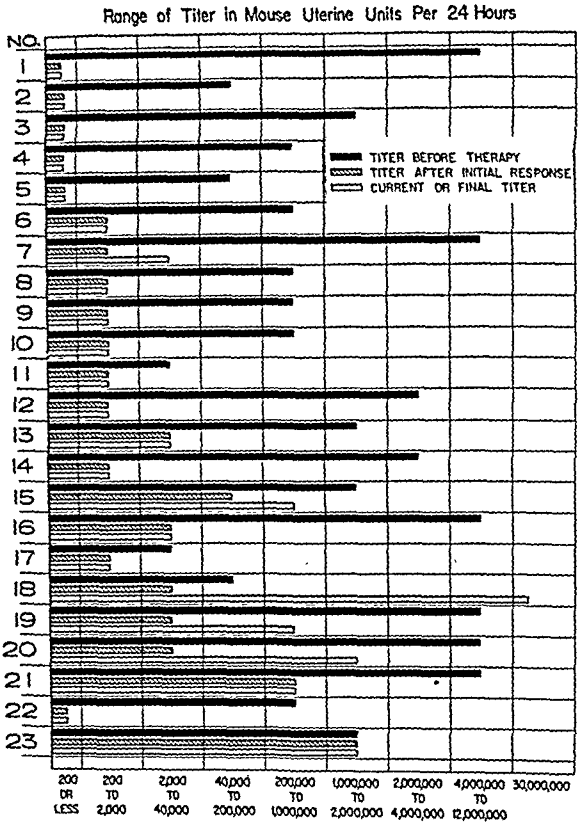

Fig. 6.—Gonadotropin responses in 23 patients who received more than one course of Methotrexate.

Summary

Since fetal and maternal tissues are found to require high amounts of folic acid for their normal metabolism, the therapeutic potential of the folic acid antagonist, 4-amino-N^{10} methyl pteroylglutamic acid (Methotrexate) in the treatment of choriocarcinoma and related trophoblastic tumors has been studied in 27 women. These patients were treated according to a highly intensive regimen, in which certain toxic hazards were present. Therapeutic indexes included (*a*) serial x-rays, (*b*) physical findings reflecting pelvic, cerebral, and pulmonary involvement, and (*c*) frequent quantitative determination of the urinary excretion of chorionic gonadotropic hormone.

Remissions varying from 29 to 2 months have been induced in all but one patient who had received more than one course of therapy. In five patients these continuing remissions are attended by no radiologic, physical, or hormonal evidence of residual disease. In 11 patients showing an initial remission, Methotrexate resistance has been encountered with varying manifestations of persistent or progressive disease. Six patients initially responded but subsequently developed resistance to Methotrexate and died. One patient died of drug toxicity during remission, and drug toxicity may have contributed to the death of two other severely debilitated patients.

These experiences demonstrate that metastatic trophoblastic disease is susceptible to treatment and that significant clinical remissions may be obtained. Hence, although the chemotherapeutic regimen is somewhat hazardous, the morbidity and mortality may be regarded as acceptable.

IRRADIATION CYSTITIS

Thomas L. Pool, M.D., Rochester, Minn.

Whether one form of irradiation therapy is more likely than another to initiate an irradiation cystitis is unknown. Certainly, the variations in sensitivity among patients must be great. Patients who have only mild symptoms may need no treatment. Patients who have superimposed inflammatory processes benefit greatly from the use of modern chemotherapeutic agents and antibiotics plus local therapy, such as lavage of the bladder and the instillation of a 5% solution of a mild silver protein preparation. Spontaneous healing is much better than some procedure for urinary diversion.

Irradiation cystitis is one form of factitial cystitis. This entity is not common, yet the frequency of occurrence is increasing. More and more female patients who have malignant lesions of the uterus, and especially the cervix, are being treated with either x-rays or radium. At present, many patients with carcinoma of the cervix receive both forms of therapy.

The true incidence of irradiation cystitis will never be known. Patients become lost to record, or follow-up examination is impossible. The symptoms of some patients are so mild and prevail for such a short time that no mention of them is made to the attending physician. In the years 1950 through 1954, 50 female patients with a diagnosis of irradiation cystitis were seen in the section of urology of the Mayo Clinic. Some of these had received irradiation therapy at the Mayo Clinic and some had been treated elsewhere. All had carcinoma of the uterus, cervix, or ovary.

The etiological agent of course is the irradiation therapy used in such cases. Whether one form of therapy is more likely than another to initiate a reaction in the bladder is unknown. Certainly, the variations in sensitivity among patients must be great. Moreover, there seems to be no correlation between the amount of therapy administered and the intensity of the reaction.

The range of ages may vary greatly. Two of our 50 patients were between 20 and 29 years of age, 13 between 30 and 39, 13 between 40 and 49, 15 between 50 and 59, and 7 between 60 and 69. No patient in any single decade of life appears to be immune, and there is no preponderance of reactions in any one decade. This is more or less what would be expected of such a condition. Of great interest is the length of time between irradiation and the development of the reaction in the bladder. Of our 50 patients, 22 showed a reaction within the first year, 8 by the second year, 5 by the third, 4 by the fourth, 2 by the fifth, 3 by the sixth, 2 by the seventh, and 1 by the eighth year. One patient showed no reaction until the 11th year, one after 12 years, and one after 14 years. This once more emphasizes the individual sensitivity or resistance to the therapy used.

Read before the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Clinical Appraisal

Pathological Aspects.—The pathological process has been described by many authors. There appears to be no doubt that the circulation of the bladder is impaired. An inflammatory process also is usually present. The inflammation may be transient and later subside, or endarteritis may develop which slowly leads to ischemia. Even later, necrosis or ulceration may develop, followed by either fistula formation or scar.

Any part of the bladder may be involved in the pathological process. When radium has been used, the most common site is the posterior wall in the midline and just back of the interureteric ridge. When vesicovaginal fistula is present, this ridge is the usual site of the opening in the bladder.

Symptoms.—As has been said, the symptoms associated with irradiation cystitis may be very mild and persist for only a short time. However, other patients may complain strenuously of severe symptoms, such as frequency of urination, dysuria, urgency of urination, and pain in the area of the bladder. Thirty of our patients had gross hematuria as the predominant urinary symptom. Some noted the hematuria only on one or two occasions. Others suffered gross hematuria over a long period.

Diagnosis.—The diagnosis of irradiation cystitis may be difficult at times. The history may be helpful. Any patient who has urinary symptoms with a history of irradiation therapy to the uterus or cervix of the uterus should be suspected of having irradiation cystitis. An ordinary type of inflammatory cystitis may confuse the cystoscopic picture. Likewise, interstitial cystitis may make the diagnosis uncertain. At times, even tuberculous cystitis may obscure the correct diagnosis. Certainly, any type of grossly inflamed vesical mucosa may leave the correct diagnosis uncertain for a time. Moreover, extension of a lesion from an extraurinary source or a primary lesion of the bladder may have to be excluded.

Cystoscopic Findings.—The earliest cystoscopic finding seen after irradiation therapy is marked edema of the mucosa of the bladder. The mucosa is glistening and white, with a suggestion of free fluid under the vesical mucosa. This process may disappear and leave the mucosa entirely normal or it may change to hyperemia, with the blood vessels distended over most of the wall of the bladder. Later, this picture may change until only petechial areas are seen, with small blood vessels extending from small reddened centers which may or may not be ulcerated. Such areas may remain unchanged for years. They may also fade gradually away, to be succeeded by scarring in the central area of inflammation.

The severe and really late cystoscopic finding is an ulcerated lesion with a raised, granulomatous edge and a central area of sloughing. This lesion also may be covered with a variable amount of mucus. Such a lesion may develop any place in the bladder. As a rule it is found in the midline, just back of the interureteric ridge. However, the base of the bladder or the lateral walls also may contain such a lesion. This is the pathological process which must be distinguished from a primary neoplasm or from an extension of an extraurinary tumor. The mucus and sloughing tissues may be removed by the blunt specimen forceps, or the heel of a direct-vision cystoscope may be used to scrape the material away, down to the granulation tissue. A sharp specimen taker then may be used to remove material for microscopic examination. Such a procedure is not without danger, since perforation of the bladder has been known to occur when tissue is thus taken. Frequently, blood may ooze rather severely from the area when the specimen is removed for biopsy. This area should not be fulgurated, since loss of blood supply to this portion of the bladder already has been sustained. Continuous irrigation of the bladder with saline solution or a diluted solution of silver nitrate will be sufficient to manage any such hemorrhage likely to be seen.

Sometimes this chronic lesion may be covered with incrusted urinary salts. These incrustations must be removed before a satisfactory specimen for biopsy can be taken. Often the patient with such a lesion of the bladder will be benefited and the hemorrhage will be controlled if, after the specimen has been removed, the area is touched with a 20% solution of silver nitrate.

Treatment and Results

Those patients who have only mild symptoms may need no treatment. Many patients have symptoms which persist for only a short time, and they never complain again about the urinary tract. Those patients who have superimposed inflammatory processes benefit greatly from the use of modern chemotherapeutic agents and antibiotics plus local therapy, such as lavage of the bladder and the instillation of a 5% solution of a mild silver protein preparation (Argyrol). However, it is our impression that no form of medication or treatment can ensure cure of a severe lesion. The primary objective is to keep the bladder as clean as possible and to alleviate the patient's symptoms. Only time will determine if the blood supply will return sufficiently to allow healing to take place. The necrosis may become worse or a fistula may develop.

If a fistula becomes apparent, attempt at closure is of little benefit and should be withheld as long as possible. It has been known that a vesicovaginal fistula developing in a patient with irradiation cystitis has healed spontaneously. The end-result for such a patient is much better than it would be if some procedure for urinary diversion had been performed.

Thirty-one patients left the Mayo Clinic without receiving treatment to the urinary tract. Eighteen of these patients have had no further difficulty with the urinary tract to the time of this writing. We have been unable to follow the condition of seven patients. Three patients have had recurring bouts of gross hematuria. A vesicovaginal fistula developed in one patient and a rectovaginal fistula developed in another. Another patient has had repeated bouts of infection of the urinary tract.

Nineteen patients were treated at the clinic during one or more visits. Lavage of the bladder and instillation of a 5% solution of a mild silver protein preparation constituted the most common form of therapy. Three other patients underwent removal of sloughing tissues and incrustations. Several patients received repeated courses of chemotherapy. It is of interest that 12 patients remained symptom-free. Three patients have had recurrent bouts of gross hematuria. Vesicovaginal fistulas have developed in two. One patient has had recurring bouts of urinary infection. One patient underwent cutaneous ureterostomy because of obstruction to the ureters.

Conclusions

Thirty of 50 patients who had had irradiation cystitis were without symptoms of disease of the urinary tract at the time of this writing. Eighteen were not treated; 12 were treated. The objective in the care of these patients is alleviation of the symptoms and maintenance of the bladder in as clean a condition as possible in the hope that the lesions will heal naturally. In view of the serious nature of the original lesions and the therapy necessary to combat these lesions, it is somewhat surprising that more patients do not suffer from irradiation cystitis. Severe complications do occur and are to be expected.

PEDIATRICS IN TRANSITION

George M. Wheatley, M.D., New York

We live in a world of rapid change to which our own world of pediatrics is not immune. Indeed, events move so swiftly that it is difficult not to be confused or dismayed or even, at times, deeply disturbed. I was reminded of this by a stimulating exchange of letters [1] a few months ago, in the *Journal of Pediatrics*, which dealt with the trials and tribulations of pediatric practice today. A number of you no doubt recall this correspondence. The letter [1a] which sparked the whole flurry raised the question, "What is today's pediatrician for?" The author contrasted the erudite, clinical training which many young physicians receive in teaching hospitals with the actual demands of everyday practice. What is wrong, this correspondent asked, that makes at least a third of the pediatricians dissatisfied enough to wish themselves out of the practice of pediatrics? "Is it the individual or the specialty, or both?" This blast drew some quick and telling fire. The replies tended to point out that pediatric practice is satisfying, provided that (1) the individual has the proper temperament and (2) there is some reorientation of pediatric education to give adequate appreciation of health supervision.

The practice of the pediatrician has been changing under the impact of many socio-economic factors. Foremost among these is the continued improvement in the general physical, educational, and social well-being of children in the United States. As a result, the pediatrician is confronted less frequently with severely sick children and is called upon more and more for the guidance of the healthy child, the prevention of disease and trauma, and the care of the handicapped and emotionally disturbed child. The teaching of pediatrics in medical schools needs to be modified in view of this change, and research programs should recognize the new challenges and opportunities that have resulted from it.

But this correspondence points up the fact that many in pediatrics are asking this question: "What is today's, or tomorrow's, pediatrician for?" Examination of some of the underlying factors which have raised this question ought to help our understanding, our acceptance, and, indeed, our preparation for the future.

Chairman's address, read before the Section on Pediatrics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

Socioeconomic Factors Affecting Pediatrics

Foremost in socioeconomic factors, of course, is the tremendous improvement in the general physical, educational, and social well-being of children in the United States. No group in the medical profession has contributed more to these gains than pediatricians. These favorable conditions for raising children, coupled with the sustained high birth rate since the great depression of the 1930's, mean that children under 18 years of age now make up a third of the nation's total population. Families are tending to be larger and more of them are being held intact, thanks to the spectacular reductions in maternal deaths and in those from tuberculosis, pneumonia, and rheumatic heart disease in those under the age of 40.

Of the greatest significance socioeconomically has been the rising standard of living in the United States, with the average family income the highest in history. Despite the current economic situation, there is general agreement among economists that productive power will continue its further development and expansion.

We must not underestimate the public's increasing interest in health as a factor in the use of pediatric services. As physicians, we may deplore the exploitation by unprincipled advertisers of this public eagerness for better health, but there can be no doubt that health publications, the press, radio, movies, and television—the so-called mass media—have made and can continue to make health supervision a desirable and purchasable commodity, at least for children.

In the last decade, there has been a great movement of population from the cities into the outlying areas. This has brought young families to housing developments 10, 20, and 30 miles from the big cities. These new or greatly expanded communities have required many new health services. These new families want the best possible care for their children. This has attracted many young pediatricians to these areas. While it has brought excellent pediatric care to the suburbs, it has at the same time drained off some of the most promising teaching talent from the medical centers and also deprived young pediatricians of the intellectual stimulation of teaching institutions.

Impact on the Content of Practice

One of the most disturbing results of these socioeconomic factors is the gap, which may be widening as noted above, between the practitioner of pediatrics and the teacher of pediatrics. Davison[2] has called this the "pediatric shift." In other words, practice is changing from one largely composed of the diagnosis and treatment of very sick children to one in which child health supervision, diagnostic problems, and management of special disorders, such as prematurity and crippling conditions, predominate. Some schools have not caught up with this change. Hansen's recent survey[3] of a statewide group of pediatricians to determine the inadequacies of past pediatric training and experience indicates that about half thought there should have been more emphasis during their training on allergy and psychiatric aspects of behavior problems. None of the group felt that he should have had more training in such categories as "water and electrolyte disturbances, metabolic disorders, contagious diseases, parasitology, hematology, and typically diagnostic problems."

Hospital admissions have changed too. Lawson[4] points out that improvement in nutrition has almost eliminated the need of inpatient care of children for disorders resulting from nutritional causes. Immunization and antibiotic therapy have had even greater influence on hospital admissions, though indiscriminate use of antibiotics has contributed several new problems, such as resistant infections and side-reactions to antibiotics. Trauma and accidental ingestion of toxic substances have become more frequent phenomena in practice as diseases have been more effectively controlled.

These changes are beginning to affect pediatric education. Some educators are now placing more emphasis on preparing the pediatrician as a physician to children in health and for minor as well as for severe illnesses. More attention is being given to providing medical students and pediatric residents with opportunity for long-term follow-up of the same children, including well children, to give a greater appreciation of the many factors which influence a child's physical and emotional health over a period of time. Fischer[5] has called attention to the widening scope of the pediatrician's world to include familiarity with accident prevention, adoption problems and practice, school health programs, handicapped children, and problems of the adolescent. Crook and his associates[10] would add allergy to this list. Helping to fill the void in the practicing pediatrician's knowledge of these subjects are some of the standing committees of the American Academy of Pediatrics, such as the accident prevention, adoptions, and school health committees. More opportunity should be given pediatric residents to secure knowledge of social pediatrics through arrangements with community health and welfare services. The Academy's Committee on Medical Education has played a most influential role, especially through its regional conferences, in helping to close the gap betwen the practitioner and the educator. They have permitted comparisons among medical centers in regard to the teaching programs and brought together teachers, research workers, and those in practice. There is general agreement that for general practice a rotating internship should be at least two years in length with a minimum of six months spent in pediatric training. For the present, the view is that at least two years of pediatric training is required for eligibility for examination by the Board of Pediatrics. Postgraduate education is being recognized as of increasing importance, and the Academy's Committee on Education is developing a special program which should be a significant contribution toward strengthening relationships between teachers and practitioners.

In considering the future of pediatrics, and especially the future of the practitioner of pediatrics, we need to consider the possibility that the work of the pediatrician may expand to include a broader age group. For some years, pediatric leaders have called attention to the importance of providing service to the adolescent age group, and a number of pediatricians cover this age range. The horizon of pediatrics is broader perhaps than many of us visualize. For example, at the 54th Annual Congress on Medical Education and Licensure which was held in Chicago this past winter, one of the major emphases was on the need to prepare physicians to practice family medicine.[6] This raises the interesting possibility that in the pediatrician we may have the prototype of the family doctor of tomorrow. Certainly, no other branch of medicine is at present so well prepared to apply and develop the principles of preventive medicine and to care for the entire family's health.

Need for Research and Its Support

In looking to the future, and regardless of the eventual metamorphosis of pediatrics, it is imperative to broaden the scope of pediatric research. In our concern for the adequate preparation of physicians to practice pediatrics, we cannot lose sight of the primary responsibility of the medical school to advance knowledge and not merely to impart it.

Darrow[7] recently reviewed the impact on pediatrics of the brilliant group of investigators which comprised the pediatric teaching and research group at the Harriet Lane Home for Invalid Children when John Howland became the first full-time professor of pediatrics in 1913. Marriott, Parks, Blackfan, Powers, Gamble, Kramer, and so many others of that group brought many disciplines to bear on the problems of infants and children, whether the fields have been biochemistry, bacteriology, virology, public health, psychology, psychiatry, or sociology. Not only has this created modern pediatrics but it has developed concepts now applied generally in medical practice: for example, the application of biochemical and physiological principles to human fluid therapy and improved nutrition, or the concept of the "whole child," which has become the "concept of the patient as a person." Perhaps the unique contribution of pediatrics has been to spearhead the development of preventive medicine as a purchasable commodity of private practice. Pediatrics has from its earliest beginnings cultivated this concept and has gradually deepened and broadened this service so that more and more pediatricians are being asked to deal with emotional problems of the child and of family life. Under the vision and stimulating guidance of its early leaders, pediatrics has, to an increasing degree, recognized and accepted the social and community responsibilities involved in medical care. The problems involved in child care today and tomorrow call for the same high dedication, imagination, and resourcefulness in both research and teaching as those which the great pediatric leaders exemplified.

There is still much to learn about children of every age group. Interesting phenomena are by no means all associated with disease. A great need exists for research into accident causation and in the study of child behavior. If pediatrics is to continue to spearhead the evolution of medical practice, we must give our best young minds—the pediatric residents who are to be the great teachers and researchers of the future—opportunity to investigate problems in genetics, enzyme systems, nutrition, epidemiology, and the behavioral sciences, as well as the physical sciences. In this connection, voluntary agencies who have raised large sums of money from the public should be encouraged in their efforts to take a broad concept about using their funds to support medical education and research. The medical profession, which has ties with many voluntary health groups, could be more active in helping these worthy organizations develop policies which permit the use of their moneys for basic research and assistance to medical schools. One way is to recognize that it costs a medical research institution a substantial amount of money —the "overhead"—to conduct a research program. Most voluntary agencies making research grants to medical schools recognize this by supplementing the amount of the research grant by 8 to 10%. Cost studies by major universities show that the real cost is nearer 50%.[8] Failure to approximate this cost is one of the major factors in the financial plight of medical education and research. Too much emphasis on purely clinical investigations or studies of methods and techniques in the disease category of the voluntary health agency is also self-defeating. Breakthroughs in a number of the major disease categories, such as the cardiovascular-renal, neoplastic, neurological, and metabolic disorders, is most likely to come from more intensive work in fundamental life processes. Some of the voluntary agencies have made encouraging contributions in these directions, notably, the National Foundation for Infantile Paralysis, the American Heart Association, the American Cancer Society, and the Association for the Aid of Crippled Children.

Closer Ties Between Practitioner and Teacher

In discussing the importance of the teacher and the researcher to the future of pediatrics, it is necessary to recognize that a basic reason for the profound influence which our specialty has had on child health and on medicine in general has been close understanding and active cooperation on pediatric problems between those in academic work and those in practice. Those who helped create this section in the American Medical Association 70 years ago represented both; the same is true of the American Academy of Pediatrics. Professional groups primarily composed of teachers and investigators are most necessary and desirable, but it is not good for children or for the future of the specialty for too much isolation to exist between these interests. Isolation breeds intolerance, suspicion, and misunderstanding. Let us find more ways of working together. One illustration of this has been the active participation of the Academy, the American Pediatric Society, and the Pediatrics Section of the A. M. A. is working with the American Board of Pediatrics during the past year in a review of its policies and procedures.

This discussion was begun on a note which indicated that some in pediatrics may be dissatisfied with their lot or worried about their future. I have tried to outline some of the factors which might account for some of these feelings. The point has been made that pediatrics, as a specialty, is changing—a fact perhaps obvious to all—but this review may help gain a better perspective of ourselves at the moment and our prospects. In essence, the dissatisfactions with pediatric practice lie more with the individual's own misconceptions of the realities of pediatric practice today and with the individual's attitude toward children. As Powers[9] has expressed it, "There are many aspects of pediatric experience which attract graduates in medicine, but I think the chief magnet is the enjoyment and satisfaction of working with and for children—not sick children, not healthy children, not handicapped children, not infants, toddlers, teen-agers or adolescents—just children!" The future can be looked at with confidence by those who are fond of children. The public wants the best for the children. The influences mentioned earlier of health education, growth in families, and the development of voluntary health insurance will bring better medical care within the reach of more and more families, but it is important for us to know that pediatrics is in transition from a disease-oriented specialty to a child-rearing specialty.

Conclusions

In spite of the health education of the public carried on for so many years, there is still a disheartening apathy on the part of many with regard to maintaining their own health. We have seen evidence of this apathy in regard to adult acceptance of the poliomyelitis vaccine, in the reluctance of communities to adopt fluoridation, and in the failure of so many adults to avail themselves of health examinations even when they are readily available. What can be more challenging and rewarding than to develop for the adult segment of our population the same interest in caring for their own health as many now have for their children's health? More and more young people are reaching maturity with some appreciation of what a physician can offer through health supervision. The pediatrician has developed and is continuing to develop a market, so to speak, for health supervision at all ages.

SERUM TRANSAMINASE ACTIVITY IN NEONATAL PERIOD

VALUABLE AID IN DIFFERENTIAL DIAGNOSIS OF JAUNDICE IN THE NEWBORN INFANT

Simon Kove, M.D., Stanley Goldstein, M.D.
and
Felix Wróblewski, M.D., New York

Clinical and laboratory data have been obtained showing that the differential diagnosis of neonatal icterus is facilitated by serial measurements of transaminase activity of the serum. In 63 normal newborn infants the glutamic oxalacetic transaminase (GO-T) activity levels ranged from 13 to 120 units; for glutamic pyruvic transaminase (GP-T) the range was 12 to 90 units. In infants with neonatal icterus classified as physiological, transaminase activity remained within the normal range, and no correlation was found between the intensity of the icterus and the transaminase activity. Data from 15 infants (including previously published data on nine), with jaundice due to pathological conditions, indicate that characteristic patterns of enzyme activity appear for each of the varied causes of neonatal icterus. In infants with extrahepatic infection and usually in those with hemolytic conditions the enzyme activity remains within the normal range. However, in an infant with a fulminant form of hemolytic disease of the newborn, GO-T activity alone was transiently elevated to about 300 units. In all cases of biliary obstruction the GO-T and GP-T values rose gradually to levels below 800 units. In an infant with very mild acute hepatitis (homologous serum) the enzyme activity rose sharply during the stage of increasing hyperbilirubinemia to well above 800 units (to 1140 units) and fell sharply thereafter. Serial determinations of serum transaminase activity in cases of neonatal icterus, therefore, aid in recognition of patients requiring surgery.

Icterus of unknown origin in the neonatal period frequently presents a difficult problem in diagnosis. During this time of life the history, physical examination, and available laboratory techniques are often of limited value in providing adequate clues from which a correct etiological diagnosis may be made. This is in contrast to the situation in adults, in whom these same procedures usually supply the necessary data for establishing the cause of the jaundice. Thus a diagnostic tool which may help to clarify the clinical picture would be of material aid to the clinician faced with the problem of differential diagnosis of jaundice in the newborn infant.

Transaminases are enzymes which catalyze reactions involving the transfer of an amino group from one amino acid to a keto acid with the formation of a new amino acid. An increase in transaminase activity in the serum occurs in the presence of hepatocellular injury or necrosis, presumably as a result of liberation of the enzymes from the damaged cells. Since measurement of transaminase activity has proved of value in the diagnosis of liver disease in adults, it was felt that application of this technique to the newborn infant with jaundice could be a diagnostic aid.[1] Our preliminary observations in previous studies[2] indicated that serial measurements of activity of glutamic oxalacetic transaminase (GO-T) and of glutamic pyruvic transaminase (GP-T) in the serum offered promise of being of considerable assistance in defining the cause of icterus during the neonatal period. In the present report, observations are presented of transaminase activity in the serum in an additional group of infants in the neonatal period with jaundice due to pathological conditions. These findings are summarized with those of the previous investigations. From these combined studies, distinctive patterns of enzyme activity appear to emerge as characteristic of the varied causes of neonatal icterus, with consequent significant prognostic and diagnostic implications.

Method and Case Material

In these investigations serums for measuring GO-T and GP-T activity were obtained from normal term infants from the newborn infants' nursery of Bellevue Hospital and also from infants with neonatal jaundice associated with pathological conditions from the Children's Medical Service of the same hospital. The group studied previously included 63 normal newborn term infants, to establish normal neonatal physiological levels of serum enzyme activity, and 9 infants with jaundice of pathological origin.[2] This latter group consisted of seven infants with hemolytic disease of the newborn

Read before the Section on Pediatrics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

due to Rh incompatibility, one infant with inspissated bile syndrome, and one infant with extrahepatic biliary obstruction (agenesis of common bile duct). To this group are now being added five more infants with neonatal icterus due to pathological states and these will be reported in detail. These cases are comprised of two infants with hemolytic disease of the newborn resulting from ABO incompatibility, one infant with jaundice associated with extrahepatic infection, one infant with agenesis of the entire biliary tract, and one infant with acute hepatitis (presumably homologous serum type).

All infants with jaundice of pathological origin were less than 2 months of age at the time of onset of observations, with a single exception. This was a premature infant who was born after a 28-week gestation with a birth weight of 1,340 Gm. (3 lb.) and who developed acute hepatitis at 5½ months of age.

Serial measurements of GO-T and GP-T activity in serum were obtained at frequent intervals in the infants with icterus caused by pathological conditions, to obtain clear pictures of the course of enzymatic activity in the various disease states associated with neonatal jaundice. The spectrophotometric method was employed in determinations of GO-T and GP-T activity in the serum, and results are expressed as units per milliliter of serum per minute.[3] In normal adults using this method, the range of serum enzyme activity for GO-T varies from 8 to 40 units and that for GP-T varies from 5 to 35 units. Enzyme activity exceeding these values is considered indicative of a pathological condition.

Results

Normal Newborn Infants.—In a group of 63 newborn term infants, it was found that the normal range of activity for GO-T and GP-T in serum was greater during the first week of life than that for adults.[2] The range of activity for GO-T was found to be 13 to 120 units. That for GP-T was 12 to 90 units. The activity of the enzymes was generally lower in cord blood than at any other time in the early neonatal period. These findings indicate that levels of activity up to 120 units for GO-T and 90 units for GP-T may be considered normal for the early neonatal period.

Physiologic Hyperbilirubinemia in Newborn Infants.—In the group of 63 normal newborn infants discussed above, it was found that the degree of hyperbilirubinemia, which is so common for this time of life, did not affect the level of serum GO-T and GP-T activity. No relationship could be demonstrated to exist between the degree of hyperbilirubinemia and the level of activity of either serum enzyme, despite indirect serum bilirubin levels of 10 to 15 mg. per 100 ml. in 13 infants, and 15 to 33 mg. per 100 ml. in 6 infants.

Neonatal Icterus Secondary to Extrahepatic Infection.—The course of enzyme activity in neonatal icterus due to infection was studied in a 36-day-old infant.

Case 1 (table 1).—An infant 36 days of age was admitted to the hospital with icterus of moderate degree, which was noted to have been present for three days. His weight at birth was 2,970 Gm. (6 lb. 9 oz.). The infant was acutely ill. The liver was palpable 2.5 cm. below the costal margin. The stools were yellow. Urinalysis revealed 3+ albumin and a trace of bile. Urobilinogen was present. A catheterized urine specimen showed numerous white blood cells with many clumps, and gram-negative bacilli appeared on a smear. Culture of the urine, after the institution of antibiotic therapy, was negative, and the sediment showed no cellular inclusion bodies. Penicillin, streptomycin, and chloramphenicol (Chloromycetin) caused the urine to clear within a few days. The hemoglobin level was 12.9 Gm. per 100 cc. The white blood cell count was markedly elevated (28,500 per cubic millimeter), with 70% polymorphonuclear leukocytes and 9% band cells. Hematological studies yielded normal results. The alkaline phosphatase activity was 11.4 Bodansky units per 100 cc. The liver flocculation tests were normal. The Mazzini test was negative. The blood nonprotein nitrogen level was 68 mg. per 100 ml. The intravenous pyelogram was normal.

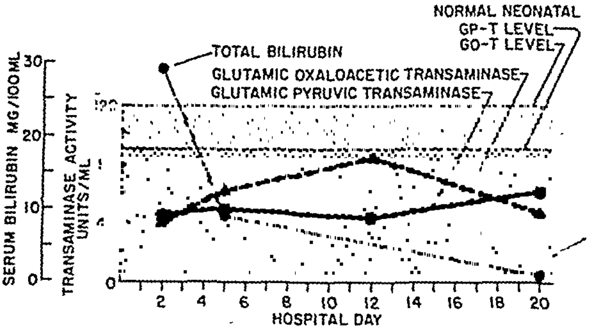

Fig. 1 (case 1).—Glutamic oxalacetic transaminase (GO-T) and glutamic pyruvic transaminase (GP-T) levels in serum of 36-day-old infant with jaundice associated with extrahepatic infection (pyelonephritis).

There was rapid improvement with antibiotic therapy. The jaundice disappeared by the sixth day, with a decrease of total serum bilirubin from an initial level of 29 mg. per 100 ml. (of which 20.8 mg. was the direct type) to 9.1 mg. per 100 ml. within four days. The pyuria cleared by the 11th day. The clinical course and results of serial determinations of GO-T and GP-T are recorded in table 1 and figure 1. It will be noted that the activity of GO-T and GP-T in serum remained normal throughout the course.

It appears, then, that neonatal jaundice due to infection is not accompanied by an increase in activity of either serum GO-T or GP-T when there is no associated liver disease.

Neonatal Jaundice due to Hemolytic Conditions.—Seven infants with hemolytic disease of the newborn due to Rh incompatibility were studied. It was found that in mild to severe manifestations of the disease both GO-T and GP-T activity in serum remained at normal neonatal levels. However, in a severe fulminating form of the disease the activity of GO-T was elevated up to about 300 units for several days, whereas the GP-T activity remained at the normal neonatal physiologic level throughout the active hemolytic phase. The temporary elevation of GO-T activity is not unexpected in view of the high concentration of the enzyme in red corpuscles.

† Glutamic pyruvic transaminase.

In the present investigation two infants with hemolytic disease of the newborn due to A-B-O incompatibility were studied, and their courses are summarized in table 2.

CASE 2 (table 2).—This infant's mother was a primipara whose blood type was O, Rh positive. Her undiluted serum hemolyzed A but not A_2 cells. (These findings are typical for A-B-O hemolytic disease.) The infant's weight at birth was 3,195 Gm. (7 lb. 1.5 oz.). The blood type was A, Rh positive. Jaundice was noted within the first 24 hours after birth and increased in severity. The infant was markedly icteric at 3½ days of age. The hemoglobin level dropped to 11.3 Gm. per 100 ml. when the infant was 2½ days old, and the total serum bilirubin level rose to 39.6 mg. per 100 ml. when the infant was 3½ days old. No transfusions were given. The infant was observed closely for the development of the inspissated bile syndrome, because of the severity of jaundice and degree of hyperbilirubinemia. However, this syndrome did not materialize, and the jaundice diminished rapidly. There was mild hepatomegaly. The Coombs test was negative. The stools were yellow, and there was no bile in the urine. The infant was discharged in good condition with no transfusion.

CASE 3 (table 2).—The mother of this infant had had one previous pregnancy, which was normal. Her blood type was O, Rh positive. The infant weighed 3,060 Gm. (6 lb. 12 oz.) at birth. Its blood type was A, Rh positive. At 28 hours of age the infant had marked jaundice. The hemoglobin level dropped from an initial concentration of 16.5 Gm. to 8.6 Gm. per 100 ml. and the indirect serum bilirubin level rose to 29 mg. per 100 ml. One exchange transfusion was performed. The jaundice subsided after several days. A study of serums of the mother and baby revealed strong A sensitization in the mother and typical findings of A-B-O hemolytic disease in the infant. The infant was discharged in good condition.

The activity of serum GO-T and GP-T remained within the physiologic neonatal range in both of these cases, despite the decrease in hemoglobin concentration and elevation of serum bilirubin level.

From the findings in the present and previous studies it would be anticipated that in hemolytic conditions both GO-T and GP-T activity in serum usually remain within the normal neonatal range. However, a temporary increase in GO-T activity of up to about 300 units may occur in a fulminating form of hemolytic disease.

Inspissated Bile Syndrome.—Inspissated bile syndrome is characterized by the onset during the first few days of life of (1) jaundice, (2) biliary obstruction with acholic stools, presence of bile, and absence of urobilinogen in urine, (3) increased indirect and increasing direct serum bilirubin level, and (4) negative flocculation tests.[4] Biliary obstruction persists for a variable time, from three weeks to several months, and then usually clears spontaneously. Occasionally, irreversible hepatocellular damage occurs, leading to cirrhosis. The etiology is obscure, but factors which may be involved include excessive serum bilirubin pigment and hepatic immaturity for handling the serum bilirubin load, resulting in stasis, inspissation of biliary secretions, and biliary obstruction. Small size of biliary ducts and dehydration may also play contributory roles. In one series of 53 cases of inspissated bile syndrome reported by others, 23 were associated with hemolytic disease of the newborn and 30 were of unknown etiology.[4] Other investigators found 7 cases of inspissated bile syndrome in a group of 83 infants with hemolytic disease of the newborn.[5] Cholangitis and early congenital cirrhosis have also been suggested as possible etiological factors.[4] In this syndrome surgery is contraindicated. In contrast, in extrahepatic biliary obstruction caused by atresia or agenesis of bile ducts the symptoms and signs of biliary obstruction do not resolve spontaneously, and surgical exploration is mandatory.

The enzymatic course in a case of inspissated bile syndrome previously reported [2d] incompletely is now completely summarized in figure 2. Biliary obstruction developed in an infant with fulminating hemolytic disease of the newborn at 6 days of age. It was manifested by increasing icterus, development of acholic clay-colored stools, rise in direct bilirubin level, presence of bile in the urine, and negative flocculation tests. The total serum bilirubin level rose to 40 mg. per 100 ml. After about four weeks the obstruction was relieved spontaneously. Figure 2 graphically portrays the alterations in the biliary patency, as they are reflected in the activity of the serum enzymes. Serum GO-T activity in cord blood was initially increased to 332 units. Then the serum enzyme activity decreased progressively thereafter, and reached the normal neonatal physiologic range at about 3 days of age. Serum GP-T activity was normal at birth. With the onset of biliary obstruction at 6 days of age there was an initial rise in GO-T activity, followed shortly by a rise in GP-T activity. Thereafter, the activity of both serum enzymes rose slowly and reached the moderate elevations of 390 units for GO-T and 450 units for GP-T three and one-half weeks after the onset of biliary obstruction. Then, with clearing of the obstruction, the activity of both serum enzymes decreased slowly. Normal neonatal levels for both enzymes were reached after another six weeks.

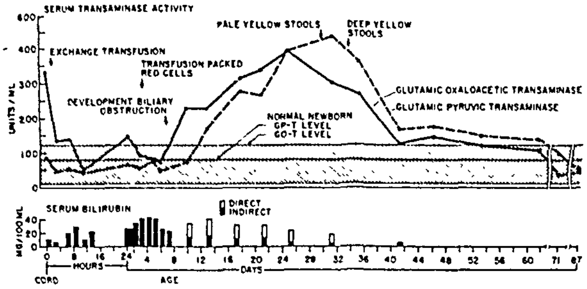

Fig. 2.—Glutamic oxalacetic transaminase (GO-T) and glutamic pyruvic transaminase (GP-T) levels in serum of a newborn infant with acute fulminating hemolytic disease of the newborn, complicated by the development of inspissated bile syndrome at 1 week of age.

Thus, the enzymatic picture in the inspissated bile syndrome appears to be characterized by a progressive sustained increase to moderately high levels of serum enzyme activity for both GO-T and GP-T. This increase begins in the very early neonatal period, simultaneously with the onset of biliary obstruction. With the relief of the obstruction the activity of the serum enzymes decreases sharply.

Neonatal Extrahepatic Biliary Obstruction.—The pattern of serum enzyme activity in a one-month-old infant (case 4) with extrahepatic biliary obstruction, which was found to be due to agenesis of the common bile duct, was documented in the previous report.[2d]

CASE 4.—A one-month-old infant was admitted to the hospital with a history of jaundice of unknown duration. Clinical and laboratory evidence of biliary obstruction were present. The direct serum bilirubin level rose to 24 mg. per 100 ml. Frequent serial determinations over a four-week period of time indicated a progressive gradual increase in serum enzyme activity from initial levels of 112 units to 630 units for GO-T and from 128 units to 720 units for GP-T. Thereafter, the activity of both enzymes leveled off over the following four weeks at a lower range below 500 units, which persisted until surgical exploration when the infant was about 3 months of age. At operation the common bile duct was found to be entirely absent although the hepatic ducts were intact. The gallbladder was distended with bile, and there was evidence of biliary cirrhosis. A choledochoenterostomy was performed, but the infant died one week postoperatively of an ascending cholangitis.

CASE 5 (table 3).—This infant, with extrahepatic biliary obstruction, was admitted at 50 days of age with a history of increasing jaundice from birth and clay-colored stools of two weeks' duration. The child's weight at birth was 3,600 Gm. (8 lb.). Prenatal and postnatal courses were uneventful. The stools had been yellow until two weeks before admission. The urine had always been dark yellow. The mother had been hospitalized one and one-half years previously for one week because of jaundice. Her blood type was A, Rh positive.

Physical examination revealed moderate jaundice of the skin and sclerae. The weight of the child was 4,200 Gm. (9 lb. 5 oz.). The liver was palpable 4 cm. below the costal margin.

There were signs of biliary obstruction: The stools were acholic, with no urobilin, and bile was present in the urine and urobilinogen absent. There were no cellular inclusion bodies in the urinary sediment. Coombs' test was negative. The blood type was O, Rh positive. Hemotological studies yielded normal results. The Mazzini test was negative, and liver flocculation tests yielded normal results. The alkaline phosphatase activity was 13.5 Bodansky units per 100 cc.

The jaundice and signs of biliary obstruction continued until surgical exploration on the 28th hospital day. At operation, agenesis of the entire extrahepatic biliary tract and gallbladder was found, and no surgical correction was possible. Biopsy of the liver revealed biliary cirrhosis. The postoperative clinical course was favorable, despite persistence of jaundice and signs of biliary obstruction. The infant was discharged from the hospital on the 56th day in good general condition and was referred to the clinic for further observation.

In this infant with extrahepatic biliary obstruction the course and results of serial measurement of enzyme activity are recorded in table 3 and figure 3.

TABLE 3.—*Serum Transaminase Activity in Fifty-Day-Old Infant with Jaundice Due to Agenesis of Entire Extrahepatic Biliary Tract*

* Surgical exploration done on 28th hospital day.
† Glutamic oxalacetic transaminase.
‡ Glutamic pyruvic transaminase.

It will be noted that the initial levels were mildly elevated to 276 units for GO-T and 200 units for GP-T. For the next three and one-half weeks the enzyme activity increased slowly to 510 units for GO-T and 280 units for GP-T. The activity then decreased to 305 units and 156 units for GO-T and GP-T respectively. After the operation the enzyme activity varied from 520 to 420 units for GO-T, and 223 to 232 units for GP-T.

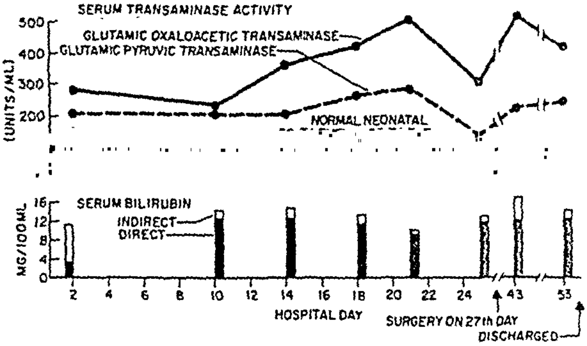

Fig. 3 (case 5).—Glutamic oxalacetic transaminase (GO-T) and glutamic pyruvic transaminase (GP-T) levels in serum of a 50-day-old infant with jaundice caused by agenesis of entire extrahepatic biliary tract.

Of striking interest is the similarity in the pattern of enzyme activity in these two cases of extrahepatic biliary obstruction. There was an initial mild increase in enzyme activity in both infants. This was followed by a progressive rise in the first case to levels of 630 units and 720 units for GO-T and GP-T, respectively, and in the second case to 510 units and 280 units for the two enzymes respectively. Thereafter, in both infants prior to surgical exploration there was a leveling off of the enzyme activity at a lower, although still increased, range. Although the significance of this "leveling off" process is not entirely clear, it may represent a decreased rate of active hepatocellular damage after an initial maximum is reached.

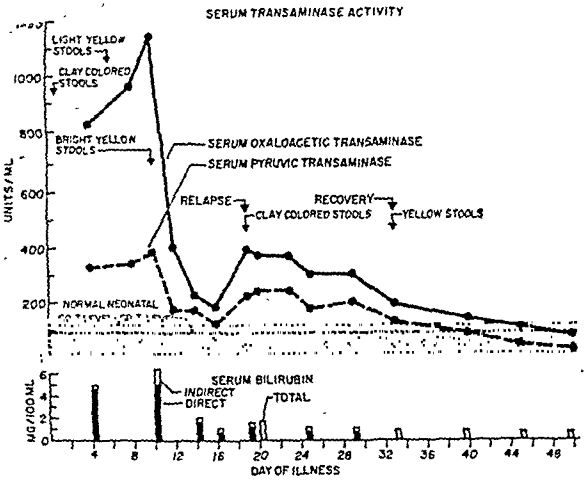

Fig. 4 (case 6).—Glutamic oxalacetic transaminase (GO-T) and glutamic pyruvic transaminase (GP-T) levels in serum of a 5½-month-old premature infant with acute hepatitis (presumably homologous serum type).

Jaundice in Infancy Associated with Acute Hepatitis.—The pattern of enzyme activity in acute hepatitis in early infancy was studied in an infant who was born prematurely. The results are recorded in table 4 and figure 4.

Case 6 (table 4).—This infant was born after 28 weeks' gestation. The weight at birth was 1,340 Gm. (3 lb.), and it decreased to 1,160 Gm. (2 lb. 9 oz.) within one week. The mother (gravida 3, para 3) was a drug addict (heroin). She denied any previous history of jaundice. The infant progressed well but remained at the hospital from birth because of socioeconomic factors. The blood was studied on several occasions during this period. At 5½ months of age, although in terms of maturity the infant would be considered to be the equivalent of 2½ months of age, he weighed 4,080 Gm. (9 lb. 1 oz.). At this time a sample of serum obtained for routine study was noted to be icteric, and analysis indicated a bilirubin concentration of 5 mg. per 100 ml. Low-grade fever had been present for three days previously and had been attributed to a mild pharyngitis.

Examination revealed questionable scleral icterus. The liver was palpable 1.5 cm. below the costal margin. The stools were clay-colored over the next two days. Bile was present in the urine (1+), as was urobilinogen in a 1:2 dilution. Galactose was absent, and there were no cellular inclusion bodies in the sediment. A diagnosis of hepatitis (probably homologous serum type) was made.

* Glutamic oxalacetic transaminase.
† Glutamic pyruvic transaminase.

The total serum bilirubin level rose to 6.4 mg. per 100 ml. over the next few days and then dropped rapidly. Complete investigation for other etiological agents was negative. The cephalin flocculation level was 0. The thymol turbidity level was 0-1.6 units. The gamma globulin level was 0-1 Kunkel units. The alkaline phosphatase activity was 2.7 Bodansky units. The level of blood cholesterol was 147 mg. and of cholesterol esters 125 mg. per 100 cc.; the blood nonprotein nitrogen level was 44 mg. per 100 ml., and the albumin-globulin ratio was 3.7/2.1. The Mazzini test was negative. The blood type was B, Rh positive. The Coombs test and heterophil antibody test were negative. The blood culture was negative. The hemoglobin level was 11 Gm. per 100 cc. The hematological studies were normal, as were the mother's liver function tests. The dye and complement fixation tests were negative for toxoplasmosis. Roentgenologic studies failed to reveal any intracranial calcifications.

The infant was not acutely ill at any time and was asymptomatic except for mild anorexia and occasional emesis for several days. The questionable icterus disappeared by the eighth day, and the stools were light yellow; bile was absent from the urine. The stools were bright yellow by the 12th day. The clinical manifestations were of such mild degree as to have most probably escaped detection even in a hospital, had it not been for a routine sampling of blood.

On the 19th day after the onset of illness a temporary relapse occurred, with the development of fever and clay-colored stools. A low-grade febrile course persisted for about seven days, with the temperature ranging from 100 to 102 F (37.8 to 38.9 C), and clay-colored stools continued for about two weeks, with urobilin present in diminished concentration. Total serum bilirubin levels did not rise above 1.5 mg. per 100 ml. The presence of urobilin in the stool, as well as the presence of urobilinogen and absence of bile in the urine, indicated that the biliary obstruction was incomplete at this time. After this temporary relapse the infant made an uneventful recovery.

With this mild degree of involvement, the pattern of serum enzyme activity would appear to assume striking significance. The initial level for GO-T activity was 824 units, and that for GP-T was 328 units. Thereafter the enzyme activity increased to peaks of 1,140 units for GO-T and 380 units for GP-T and then dropped sharply and rapidly. A temporary sustained increase in activity in both serum enzymes occurred simultaneously with the onset of the relapse. This increased activity continued for the duration of the relapse and then decreased rapidly. It will be noted that, while GP-T activity was never more than only moderately elevated, the activity for GO-T, even at the onset of the illness, was increased beyond levels obtained for any other cause of neonatal icterus. No explanation can be offered at this time for the considerably lower range of activity for GP-T than that for GO-T.

The findings suggest that even in the mildest cases of hepatitis a sharp increase in enzyme activity in serum for either (or both) GO-T and GP-T beyond 800 units, followed by a rapid fall, may be observed. The possibility that even mild forms of acute hepatitis may be differentiated from neonatal jaundice of other origin by this high level of serum enzyme activity is of diagnostic importance. Investigations in adults and experimental animals suggest that more severe forms of hepatitis would be expected to demonstrate higher levels of serum GO-T and GP-T activity than those found in this infant.[6]

Comment

The patterns of serum enzyme activity for both GO-T and GP-T that evolve from these studies appear to have significant diagnostic implications in neonatal icterus, a syndrome in which the usual diagnostic procedures may be of no help and may actually be misleading.

The experience in several cases described above illustrates some of the problems involved in obtaining helpful clues from the usual diagnostic procedures. The cases of the two infants with extrahepatic biliary obstruction (cases 4 and 5) demonstrate that historical data based on inadequate and uncritical observations of parents often yield inaccurate information. In the case of the infant with agenesis of the common bile duct (case 4), the mother maintained that the stools were bright yellow right up to the time of admission to the hospital. Yet, during the period of observation at the hospital the stools were always acholic and almost white. Similarly, in the case of the infant with agenesis of the entire extrahepatic biliary tract (case 5), the mother insisted that the stools did not become clay-colored until two weeks prior to admission. The findings on physical examination were likewise often noncontributory. Finally, the lack of help from the usual laboratory techniques is demonstrated in the infant with acute hepatitis (case 6), in whom the flocculation tests were all normal. These latter results are of course the usual findings in acute neonatal hepatitis.[7] Determinations of serum alkaline phosphatase levels were of little aid in clarifying the clinical pictures. Yet the importance of proper diagnosis and therapy is highlighted by the experience reported in a group of 30 infants with inspissated bile syndrome of unknown etiology.[4] All 4 of the infants in this group who died of related causes were among the 20 patients subjected to surgical exploration.

The results of these studies suggest that the activity of serum GO-T and GP-T follows a definite pattern for each of the varied etiological factors involved in neonatal jaundice, and thus may be of value in diagnosis. In the early neonatal phase levels of activity up to 120 units for GO-T and 90 units for GP-T may be considered as being physiologic, in contrast to an upper normal value of 40 units for both enzymes in adults. In physiologic hyperbilirubinemia enzyme activity is not altered from the normal neonatal range. In neonatal jaundice associated with infection (in the absence of intrinsic liver pathology), normal neonatal physiologic levels of enzyme activity are apparently maintained. In neonatal jaundice due to hemolytic states the activity of GO-T and GP-T are usually within the physiologic neonatal levels. However, in an acute fulminating form of hemolysis the activity of only GO-T may be temporarily increased to levels of about 300 units. In biliary obstruction, whether it be the inspissated bile syndrome or the extrahepatic type (atresia or agenesis of bile ducts), the course of enzyme activity is characterized by a slow, progressive, sustained increase which will reach a peak below 800 units. It may then level off to a lower range of activity. The limited studies in this group of infants further suggest that the two types of obstruction may possibly be differentiated from each other by the fact that in the inspissated bile syndrome the rise in activity apparently begins abruptly early in the neonatal period with the onset of obstruction, whereas in the extrahepatic type the progressive increase appears to be initiated later in the neonatal period. This difference in enzyme activity between the inspissated bile syndrome and congenital extrahepatic biliary obstruction may be accounted for by the probability that the more sudden insult to the liver in the former may result in a more rapid liberation of enzyme into the blood stream. In acute hepatitis, it appears that the enzyme pattern is characterized by a rapid increase in activity during the stage of increasing hyperbilirubinemia and a sharp fall thereafter. A similar enzymatic course is demonstrable in adults with acute hepatitis, homologous serum or infectious type.[8] Furthermore, on the basis of our limited experience to date, the peak of activity reached by one or both enzymes, even in a very mild form of neonatal hepatitis, appears to be higher than in neonatal icterus of any other cause, namely, above 800 units.

TABLE 5.—*Serum Glutamic Oxalacetic Transaminase (GO-T) and Serum Glutamic Pyruvic Transaminase (GP-T) Activity in a Group of Infants with Neonatal Jaundice due to Physiological and Pathological Conditions*

	GO-T, Units/Ml. Serum	GP-T, Units/Ml. Serum
Normal adults	5-45	5-45
Normal newborn infants	5-120	5-90
Physiological jaundice	5-120	5-90
Infection (extrahepatic)	5-120	5-90
Hemolytic states		
Mild to severe	5-120	5-90
Very severe	Temporary rise up to about 300	5-90
Biliary obstruction		
Inspissated bile syndrome	Progressive slow increase to 300-800, usually initiated early in neonatal period with onset of obstruction	Similar to GO-T
Extrahepatic (agenesis, atresia bile ducts)	Progressive slow increase to 300-800, usually initiated later in neonatal period	Similar to GO-T
Acute neonatal hepatitis	Rapid increase to levels above 800 in stage of increasing hyperbilirubinemia; rapid decrease in recovery phase	Increased activity to levels above 300 in mild cases; higher levels anticipated in severer cases

An interesting illustration of the practical value of using measurements of serum enzyme activity in diagnosis in neonatal icterus was demonstrated in the infant with agenesis of the entire extrahepatic biliary tract (case 5). There was a maternal history of jaundice one and one-half years previously and a history of yellow stools in the infant until two weeks prior to admission. The serum bilirubin concentration was variable. Despite these misleading historical and laboratory data, and in the face of considerable feeling to the contrary and in favor of a diagnosis of acute hepatitis, the diagnosis of extrahepatic biliary obstruction was made with a degree of assurance from the results of serial determinations of serum enzyme activity.

Of interest is the comparison of enzyme patterns in pathological conditions in infants with those of adults. In general the enzymatic courses in biliary obstruction and in acute hepatitis are similar for both age groups. However, the peak values reached for each of the two groups differ in the two diseases. The peak value in the infants studied was found to be below 800 units in biliary obstruction and above 800 units in acute hepatitis, whereas in adults peak values remained below 400 units in biliary obstruction, and values above 400 units are usually associated with hepatitis.[8]

It may be noted that in the infant with acute hepatitis GP-T activity lagged far behind GO-T activity, although the patterns of activity for the two enzymes were similar. The peak for GP-T was 380 units; that for GO-T was 1140 units. This differs from the pattern in this disease in adults, in whom GP-T actually usually exceeds that of GO-T (unless the plasma protein albumin/globulin ratio is reversed).[9] No adequate explanation can be advanced for this significant difference in activity for the two enzymes in this infant. Differences in plasma proteins in early infancy, from those in adults, may possibly be important contributory factors.

A tabulation of the expected patterns of enzyme activity in neonatal jaundice due to the various conditions studied is recorded in table 5. The findings in this report suggest that the technique of serial measurement of serum GO-T and GP-T activity may be of important practical therapeutic significance in neonatal icterus of unknown origin. By facilitating earlier diagnostic conclusions it may be possible to permit operative exploration in surgical types of neonatal biliary obstruction prior to the development of appreciable irreversible hepatocellular damage. By the same token it may help prevent unnecessary surgical intervention in medical forms of neonatal jaundice.

The patients studied are limited in number. Further studies are required in order to test these generalizations.

Summary

The results of this investigation appear to indicate that measurements of activity of serum transaminases are of value in the etiological diagnosis in neonatal icterus.

From studies in normal newborn term infants in the first week of life, it was found that levels of activity up to about 120 units (per milliliter of serum per minute) for serum glutamic-oxalacetic transaminase (GO-T), and levels up to about 90 units for serum glutamic-pyruvic transaminase (GP-T), may be considered physiologic for the early neonatal period. This is in contrast to an upper normal level of 40 and 35 units for the two enzymes, respectively, in adults.

In physiologic jaundice of the newborn the degree of hyperbilirubinemia did not affect the activity of either enzyme.

From the study of patients with neonatal icterus caused by pathological conditions distinctive patterns of enzyme activity emerged with consequent diagnostic and prognostic implications.

In neonatal jaundice associated with extrahepatic infection normal physiologic levels of enzyme activity were maintained.

maintained.

In neonatal icterus due to hemolytic conditions, GO-T and GP-T activity usually remained within the physiologic neonatal range. However, in an acute fulminating form of hemolysis the activity of GO-T alone was temporarily increased up to levels of about 300 units.

In neonatal biliary obstruction, both inspissated bile syndrome and extrahepatic, there was a slow progressive increase in serum enzyme activity which reached a peak below 800 units, and which then leveled off at a lower range. In the inspissated bile syndrome the progressive increase in enzyme activity began more abruptly in the early neonatal period. In the extrahepatic type (atresia or agenesis of bile ducts) the increase in activity began later in the neonatal period.

In icterus due to acute hepatitis the enzymatic pattern was characterized by a rapid increase in serum enzyme activity during the stage of increasing hyperbilirubinemia, and a sharp fall thereafter. The peak activity for one or both enzymes was higher, namely above 800 units, than that in neonatal icterus of any other cause.

These findings appear to indicate that, in addition to its diagnostic importance, the information derived from serial measurements of serum transaminase activity may serve as a guide to therapy. Thus it may permit early operative intervention in surgical types of neonatal biliary obstruction, and, by the same token, it may help avoid unnecessary surgery in medical forms of neonatal jaundice.

MEPROBAMATE FOR DERMATOSES.—The most favorable results from meprobamate occurred in the cases of disseminated neurodermatitis. An excellent-to-good effect in all types of cases occurred in nearly 50%. This favorable outcome could be explained by the fact that the drug was only prescribed when tension was a predominant symptom. The reason for the good results in the therapy of seborrheic dermatitis and psoriasis is still unknown to us. Meprobamate alone was found to have very little effect on relief of pruritus and required the addition of antipruritics such as promethazine hydrochloride or acetylsalicylic acid to produce satisfactory results. It was not as efficient as the anticholinergic drugs in reducing hyperhidrosis. Allergic reactions were encountered in nearly 4% of the patients treated, and undesirable side-effects occurred in 10%. . . . Meprobamate . . . sometimes has a dramatic and favorable influence on an anxiety state. . . . It should be prescribed for the irritable, anxious, and tense patients, especially those who have reacted unfavorably to the generally used sedatives.—F. T. Becker, M.D.; M. G. Fredericks, M.D.†; J. F. Schmid, M.D., and J. L. Tuura, M.D., An Evaluation of Meprobamate in the Management of Selected Dermatoses, *A. M. A. Archives of Dermatology*, April, 1958.

BRAIN ABSCESS—A STUDY OF FORTY-SEVEN CONSECUTIVE CASES

Frederick W. L. Kerr, M.D., Robert B. King, M.D.
and
John N. Meagher, M.D., St. Louis

In most of 47 consecutive patients with proved intraparenchymatous abscesses, the source of infection could be identified either with certainty (72%) or with a reasonable index of suspicion (17%). Headache was by far the commonest complaint, being present in all but six patients. Fever was the next most common symptom. Vomiting occurred in half the patients and nausea in less than one-third. Primary excision of the abscess was considered to be the most satisfactory therapy. The method of treatment used seemed to bear no relation to the development of seizures. Changes in the level of consciousness are emphasized as being of marked prognostic significance.

Despite the widespread use of chemotherapy and antibiotic drugs, the incidence of cerebral abscesses does not appear to have declined to any appreciable degree. Thus, during the period of 1945 to 1956, 47 patients with cerebral abscess were admitted to Barnes Hospital—slightly over four cases per year.

In a 30-year period prior to the advent of antibiotics 142 patients with cerebral abscess were admitted, representing a very slightly higher annual incidence.[1] Jooma and others[2] remarked on this in 1950, and in their clinic there was an actual increase in incidence which they attributed to more patients surviving the phase of acute cerebritis and reaching a stage of encapsulation.

The present review does not cover cases of subdural or epidural abscess nor of spinal cord pyogenic disease. The series consists of 47 consecutive cases of proved intraparenchymatous abscesses. Though the astonishing results reported by Macewen[3] in a series of selected abscesses have yet to be repeated, a review of the literature[4] reveals that with antibiotics and careful surgical technique they [illegible] be closely approximated in unselected series.

The youngest patient in the group was 2 years of age, and the oldest was 67. Surprisingly, almost 50% of the cases were in patients in the first two decades of life, due perhaps to the greater frequency of sinus infections in childhood. In the third, fourth, and fifth decades there was a definite decline in incidence, while in the sixth and seventh there were only two cases each. Of the 47 cases studied, 10 occurred in patients in the first decade of life, 13 in the second, 7 in the third, 8 in the fourth, 5 in the fifth, 2 in the sixth, and 2 in the seventh.

Source and Type of Infection

In most cases the source of infection could be identified either with certainty (72%) or with a reasonable index of suspicion (17%). However, in five cases (about 10%) nothing could be found indicative of a primary site.

Forty of the cases have been classified into categories of direct extension and hematogenous source. In the 26 cases classified under direct extension, the middle ear was the source in 10, paranasal sinuses in 10, and trauma in 6; in the 14 cases classified as being of hematogenic source, the lungs were the source in 7, teeth in 3, osteomyelitis in 1, septic abortion in 1, tonsils (?) in 1, and upper respiratory tract in 1. In two patients with meningitis it was not possible to determine whether the meningitis was the source or the result of the abscess. In five patients the source was undetermined.

Whether all the cases classified under direct extension are truly so is questionable. Thus, though in many instances the route of infection is clearly recognized at operation, in other cases it is difficult to identify, and it is possible that, in these, embolization via bridging veins has occurred during coughing and straining, as previously postulated by others.[1c]

Results of culture of the abscess contents and, in some instances, of the wall, were available in 43 of the cases. Organisms were identified in 27 (60%). No significant correlation between the type of organism identified and the degree of encapsulation could be found. The organism was identified as Streptococcus in 15 patients, Staphylococcus in 5, Proteus in 5 (secondary to middle ear infection in 4), Haemophilus influenzae in 1, and Mucor in 1. There was no organism in 12 (therefore presumed sterile), unidentified cocci in 1, and a contaminant (Bacillus subtilis) in 3. No cultures were taken in four.

Due to multiple abscesses in three patients, there were 54 abscesses in the series, of which 48 were supratentorial and 6 infratentorial. In the three patients (all children) with more than one abscess,

---

one had four and two had three each. Lung infection was the source in the patient with four abscesses, while in the other two the source was doubtful. There were 21 frontal abscesses, 12 parietal, 11 temporal, 6 cerebellar, and 4 occipital. Multiloculated abscesses occurred in only six patients.

Symptomatology and Diagnostic Methods

Headache was by far the commonest complaint, being present in all but six patients; it was of varying intensity and severe only in the last stages. Fever was the next most common symptom. A preadmission history of fever was obtained in 33 patients; its occurrence was unknown in 6 and apparently had not been present in 8. Admission temperature was normal in 16 patients; it was between 37.5 and 39.0 C (99.5 and 102.2 F) in 28 patients and above 39.0 C in 3.

Vomiting occurred in half the patients and nausea in less than one-third. A history of neurological symptoms other than seizures was obtained in slightly over half the patients. Thus, nine patients had had hemiparesis or hemiplegia, four hemiparesthesia, four cerebellar symptoms, five diplopia, and seven personality changes and irritability. Preadmission seizures were noted in 17 patients, or 36% of the group. As in other reports, frontal lobe abscesses were more prone to produce seizures (six cases). Three parietal, two temporal, and one occipital abscess produced seizures, and, surprisingly, three of six uncomplicated posterior fossa abscesses were responsible for seizures, described as grand mal in two cases and questionable grand mal in one.

The true incidence of meningitis in this series could not be determined. Clinical evidence of meningitis was invalidated by the fact that tentorial and cerebellar pressure cones frequently induced nuchal rigidity, and in the absence of a lumbar puncture conclusions cannot be drawn. Lumbar puncture was performed infrequently preoperatively to avoid precipitating or aggravating a pressure cone. Two cases of frank meningitis were seen, and in other instances mild pleocytosis and elevation of protein level were observed with no abnormality in glucose or chloride level and negative smear and culture in each instance.

In using various diagnostic methods,[5] Tutton[4c] noted that electroencephalographic slow focus activity was invariably present over the lesion in 22 patients with chronic abscess, and he regarded it as a valuable adjunct in the localization of multiple and acute abscesses. In this series electroencephalography was performed in 18 of the patients with supratentorial abscesses and gave a correct localization in 13, an approximate localization in 3, and was nonfocal in 2.

Ventriculography continued to be
liable means of localization; in one i
terior fossa abscess was overlooked;
cases the lesion was correctly localized
during ventriculography, the patient became decerebrate but recovered satisfactorily after immediate surgery.

Pneumoencephalography was used in one patient who died within 30 minutes, en route to the operating room. Postmortem examination revealed a severe bilateral tentorial herniation. Angiography is being used more frequently and may prove to be the procedure of choice in patients with supratentorial lesions, since intracranial pressure relationships are not affected.

Once the diagnosis has been established, early operation must be undertaken. In this center, complete excision of the abscess, regardless of the presence of encapsulation, combined with local and systemic antibiotics has been the method favored. Of the 35 patients so treated, 30 had a satisfactory recovery despite the fact that 8 were comatose at the time of operation. Of the five patients who died, four died as a result of severe brain stem pressure; the fifth, who had an abscess due to Mucor, died in peripheral vascular collapse.

Results

Classification of Abscesses.—On the basis of operative findings, the abscesses were classified as well-encapsulated thick-walled lesions, thin-walled lesions, and unencapsulated cerebritis. The best results were obtained in the 10 patients with acute cerebritis, among whom only one patient died; aspiration followed by subsequent excision was performed in this patient. Of the 27 patients with the well-encapsulated type of lesion, 8 died. On the surface this would appear to be a strong argument against the method of treatment advocated. However, a closer analysis revealed that, of the eight patients in whom results were fatal, three were treated by aspiration followed after an interval by excision, two died before operation could be done, one was in a terminal state, and two had primary excision. Three of the nine patients with subacute abscesses died; one was treated by excision, one by aspiration, and one was not operated on due to error in interpreting the ventriculograms. In one patient the abscess capsule was not classified.

Bronchogenic abscesses constituted a group apart insofar as prognosis was concerned, since prior to the era of antibiotics the mortality was practically 100%.[6] However, of the four patients in this series only one died, death occurring before operation could be done. Of the remaining three, all made a satisfactory recovery, but one died two and one-half months postoperatively when, while in apparent good health, she went into status epilepticus.

Changes in Level of Consciousness.—Of the greatest importance is an accurate determination of the level of consciousness in those patients suspected of harboring an abscess and frequent re-evaluation in this regard in those who show signs of drowsiness, since the transition from drowsiness to coma and decerebrate rigidity may occur in a matter of hours. The patients were arbitrarily grouped (table 1) according to their degree of consciousness into three categories: alert, drowsy or obtunded, and comatose and/or decerebrate.

TABLE 1.—*Changes in Level of Consciousness in Forty-seven Patients with Brain Abscesses*

Level of Consciousness	Prior to Admission	On Admission	Prior to Surgery	Results: Lived	Results: Died
Alert	21	16	12	12	0
Drowsy or obtunded	23	22	18	15	3
Comatose and/or decerebrate	3	9	17	7	10

It is evident from this that deterioration in consciousness is a symptom of the greatest value in timing operation and is of considerable prognostic import. Thus, of those patients who showed no clouding of consciousness prior to operation 100% survived, whereas 58% of the comatose, decerebrate group died. Among the seven survivors in the latter group there were three who had no subsequent neurological deficit, while two had moderate deficit, one severe deficit, and one is totally incapacitated.

The considerable perilesional edema in these patients is no doubt responsible in great part for deterioration by the well-known sequence of tentorial and/or cerebellar pressure cones, brain stem hemorrhage and anoxia, obstruction of venous and cerebrospinal fluid circulation, and consequent further rise in intracranial pressure.

Postoperative Neurological Deficit.—It has frequently been objected that total excision prior to encapsulation would lead to more severe neurological deficit than would repeated aspiration associated with local and systemic antibiotic therapy and delayed excision if required. Of the 34 patients who recovered, only one was incapacitated; this patient was treated by aspiration followed by delayed excision. Severe neurological deficit occurred in four patients, one treated by aspiration and excision and the remaining three by excision. Eleven patients had mild to moderate deficit, and all had been treated by excision. Of the 18 patients with no neurological residual, 16 had had primary excision and 2 aspiration followed by delayed excision.

Postoperative Epilepsy.—In this report, which covers some patients seen in the past two years, the incidence of seizures cannot be accurately estimated, since epilepsy may develop a number of years postoperatively (14 years, in one instance).[2] To date, 56% of the survivors in this series have had one or more seizures. Since if postoperative seizures are going to occur they usually appear within the first two years[2] after operation, one may assume that this figure will increase only slightly. There is no evidence to suggest that antibiotic therapy has decreased the incidence of seizures in these cases.

An interesting and unexpected feature was noted in this series; seven patients in the first decade of life survived, and none of these have developed epilepsy to date; this is a most unusual feature since in other reports[4c] the incidence has been similar for all age groups. In all succeeding decades the incidence was approximately 50%, with a maximum of six of seven patients developing epilepsy in the fourth decade (5 of 10 survivors who were in the second decade of life, 3 of 5 in the third, and 1 of 4 in the fifth; the one patient in the sixth decade was affected, and the one in the seventh was not). It is possible, as more time passes, that the incidence of seizures in the youngest age group may increase.

That postoperative epilepsy may lead to disastrous results is illustrated by the case of a 42-year-old patient (the one patient in the sixth decade) who developed a right occipital abscess secondary to bronchiectasis. This was treated by aspiration and delayed secondary excision. She had an uneventful postoperative course with a moderate residual hemiparesis. Two and one-half months after discharge she went into grand mal status and died shortly after readmission. No anticonvulsant medication had been given postoperatively, and it was felt that in the older age group routine anticonvulsant therapy should be considered in view of the high incidence of seizures. Electroencephalography may be of value in making a decision and in following these patients in anticipation of changing paroxysmal focal patterns.

The relationship between the location of the abscess and the occurrence of postoperative seizures is illustrated in table 2. About one-half of those patients having abscesses in the frontal and parietal areas can be expected to develop convulsions, a feature which may help to determine which patients should be treated with prophylactic anticonvulsants. These patients, except for one who died in status epilepticus, are under satisfactory medical

TABLE 2.—*Relationship Between Location of Abscess and Incidence of Postoperative Seizures*

Abscess: Type	Abscess: No.	Patients Having Seizures, No.: Grand-Mal	Patients Having Seizures, No.: Focal
Frontal	21	7	3
Parietal	12	1	4
Temporal	11	2	1
Occipital	4	1	...
Cerebellar	6	...	...

control, but two required cortical scar excision before anticonvulsants were effective. There appeared to be no correlation between the type of abscess excised (i. e., well-encapsulated or cerebritis) and the incidence of seizures postoperatively.

The occurrence of preoperative seizures apparently has no bearing on the incidence of postoperative epilepsy. Thus, of the 18 patients with postoperative convulsions, 11 had had no preoperative seizures. Of 12 patients with preoperative seizures, 6 had convulsions postoperatively.

Mortality.—The total mortality for the series was 14 patients, or 29%. This included all patients seen during the period covered by the survey, some of whom were considered to have hopeless cases and others who died prior to operation. Seven of these patients had marked cerebral edema and brain stem hemorrhages at postmortem examination.

Of the remaining seven, one died as a result of herniation of the uncus during pneumoencephalography, one died 24 hours after ventriculography in which a cerebellar abscess was overlooked, one from Proteus septicemia resistant to all antibiotics, another from peripheral vascular collapse with an abscess due to Mucor, two from status epilepticus two days and two and one-half months postoperatively, respectively, and one due to a probable recurrence in which it was felt that a daughter abscess might have been overlooked, though autopsy confirmation could not be obtained.

Of the 44 patients operated on, 34 recovered, giving a mortality of 22%. Fourteen were comatose or decerebrate, and in them the mortality was 50%, whereas in the 30 who were alert, drowsy, or obtunded, the mortality was only 10%.

Comment

Two main methods of treating cerebral abscesses are advocated at this time. One consists in aspiration of the contents with local instillation of antibiotics and thorium dioxide (Thorotrast),[7] leading to decompression and subsequent shriveling of the capsule; if x-ray studies show unsatisfactory progress, craniotomy and excision is then performed.

The other method, introduced by Vincent[8] for the well-encapsulated abscess and subsequently extended by LeBeau,[9] Fincher,[10] Schwartz and Roulhac[11] and Meirowsky and Harsh[12] to cover the more acute varieties, consists in primary excision regardless of the stage of evolution, followed by tight closure without drainage, associated in the past 14 years with local and systemic antibiotics. The latter method has been the method of choice in this center.

The advantages derived from this method are an immediate and lasting decompression on excision of the abscess and the removal of the stimulus to edema with consequent relief of brain stem pressure. Furthermore, the possibility of recurrence due to untapped daughter abscesses is reduced, the period of hospitalization is considerably shortened, and repeated x-ray studies and taps are not required.

The objection, which has frequently been directed at this method of treatment, that excision, particularly in the stage of acute cerebritis, leads to greater permanent neurological deficit finds no confirmation in this series in which excision produced no greater deficit than aspiration, though comparisons are exceedingly difficult to make in view of the numerous factors which must be evaluated in each case, not the least of which are the location of the lesion and the degree of progression attained by the time of operation.

The grave significance of changes in the level of consciousness has been emphasized both as an indication for prompt relief of pressure and as an index to prognosis. Since the problem of postoperative meningitis and local recurrence has been markedly reduced with the use of antibiotics, future improvement in results can be expected to result mainly from earlier diagnosis, particularly before the onset of deterioration in consciousness. This point receives strong support from the fact that only 1 of 10 patients with acute cerebritis and none of the patients who were alert died, whereas 8 of the 27 with chronic thick-walled abscesses died.

Insofar as epilepsy is concerned, this continues to be a serious sequel in a high percentage of patients, particularly in the adult group. There is no evidence to suggest that antibiotics have reduced this complication, the incidence being roughly the same as in the days prior to their introduction.

The method of treatment used likewise seems to bear no relation to the development of seizures, since an almost identical incidence of epilepsy (55%) was reported by Gurdjian and Webster[4a] for intraparenchymatous abscesses treated by aspiration or aspiration followed by delayed excision. A recent review of this problem by Northcroft and Wyke[13] in patients treated by aspiration gives a similar incidence.

Conclusions

Cerebral abscesses occur with approximately the same incidence today as prior to the introduction of antibiotics. The gross mortality for this study has been 27% and the operative mortality 22%.

Changes in Level of Consciousness.—Of the greatest importance is an accurate determination of the level of consciousness in those patients suspected of harboring an abscess and frequent reevaluation in this regard in those who show signs of drowsiness, since the transition from drowsiness to coma and decerebrate rigidity may occur in a matter of hours. The patients were arbitrarily grouped (table 1) according to their degree of consciousness into three categories: alert, drowsy or obtunded, and comatose and/or decerebrate.

TABLE 1.—*Changes in Level of Consciousness in Forty-seven Patients with Brain Abscesses*

Level of Consciousness	Prior to Admission	On Admission	Prior to Surgery	Results	
				Lived	Died
Alert	21	16	12	12	0
Drowsy or obtunded	23	22	18	15	3
Comatose and/or decerebrate	3	9	17	7	10

It is evident from this that deterioration in consciousness is a symptom of the greatest value in timing operation and is of considerable prognostic import. Thus, of those patients who showed no clouding of consciousness prior to operation 100% survived, whereas 58% of the comatose, decerebrate group died. Among the seven survivors in the latter group there were three who had no subsequent neurological deficit, while two had moderate deficit, one severe deficit, and one is totally incapacitated.

The considerable perilesional edema in these patients is no doubt responsible in great part for deterioration by the well-known sequence of tentorial and/or cerebellar pressure cones, brain stem hemorrhage and anoxia, obstruction of venous and cerebrospinal fluid circulation, and consequent further rise in intracranial pressure.

Postoperative Neurological Deficit.—It has frequently been objected that total excision prior to encapsulation would lead to more severe neurological deficit than would repeated aspiration associated with local and systemic antibiotic therapy and delayed excision if required. Of the 34 patients who recovered, only one was incapacitated; this patient was treated by aspiration followed by delayed excision. Severe neurological deficit occurred in four patients, one treated by aspiration and excision and the remaining three by excision. Eleven patients had mild to moderate deficit, and all had been treated by excision. Of the 18 patients with no neurological residual, 16 had had primary excision and 2 aspiration followed by delayed excision.

Postoperative Epilepsy.—In this report, which covers some patients seen in the past two years, the incidence of seizures cannot be accurately estimated, since epilepsy may develop a number of years postoperatively (14 years, in one instance).[3] To date, 56% of the survivors in this series have had one or more seizures. Since if postoperative seizures are going to occur they usually appear within the first two years [2] after operation, one may assume that this figure will increase only slightly. There is no evidence to suggest that antibiotic therapy has decreased the incidence of seizures in these cases.

An interesting and unexpected feature was noted in this series; seven patients in the first decade of life survived, and none of these have developed epilepsy to date; this is a most unusual feature since in other reports [4c] the incidence has been similar for all age groups. In all succeeding decades the incidence was approximately 50%, with a maximum of six of seven patients developing epilepsy in the fourth decade (5 of 10 survivors who were in the second decade of life, 3 of 5 in the third, and 1 of 4 in the fifth; the one patient in the sixth decade was affected, and the one in the seventh was not). It is possible, as more time passes, that the incidence of seizures in the youngest age group may increase.

That postoperative epilepsy may lead to disastrous results is illustrated by the case of a 42-year-old patient (the one patient in the sixth decade) who developed a right occipital abscess secondary to bronchiectasis. This was treated by aspiration and delayed secondary excision. She had an uneventful postoperative course with a moderate residual hemiparesis. Two and one-half months after discharge she went into grand mal status and died shortly after readmission. No anticonvulsant medication had been given postoperatively, and it was felt that in the older age group routine anticonvulsant therapy should be considered in view of the high incidence of seizures. Electroencephalography may be of value in making a decision and in following these patients in anticipation of changing paroxysmal focal patterns.

The relationship between the location of the abscess and the occurrence of postoperative seizures is illustrated in table 2. About one-half of those patients having abscesses in the frontal and parietal areas can be expected to develop convulsions, a feature which may help to determine which patients should be treated with prophylactic anticonvulsants. These patients, except for one who died in status epilepticus, are under satisfactory medical

TABLE 2.—*Relationship Between Location of Abscess and Incidence of Postoperative Seizures*

control, but two required cortical scar excision before anticonvulsants were effective. There appeared to be no correlation between the type of abscess excised (i. e., well-encapsulated or cerebritis) and the incidence of seizures postoperatively.

The occurrence of preoperative seizures apparently has no bearing on the incidence of postoperative epilepsy. Thus, of the 18 patients with postoperative convulsions, 11 had had no preoperative seizures. Of 12 patients with preoperative seizures, 6 had convulsions postoperatively.

Mortality.—The total mortality for the series was 14 patients, or 29%. This included all patients seen during the period covered by the survey, some of whom were considered to have hopeless cases and others who died prior to operation. Seven of these patients had marked cerebral edema and brain stem hemorrhages at postmortem examination.

Of the remaining seven, one died as a result of herniation of the uncus during pneumoencephalography, one died 24 hours after ventriculography in which a cerebellar abscess was overlooked, one from Proteus septicemia resistant to all antibiotics, another from peripheral vascular collapse with an abscess due to Mucor, two from status epilepticus two days and two and one-half months postoperatively, respectively, and one due to a probable recurrence in which it was felt that a daughter abscess might have been overlooked, though autopsy confirmation could not be obtained.

Of the 44 patients operated on, 34 recovered, giving a mortality of 22%. Fourteen were comatose or decerebrate, and in them the mortality was 50%, whereas in the 30 who were alert, drowsy, or obtunded, the mortality was only 10%.

Comment

Two main methods of treating cerebral abscesses are advocated at this time. One consists in aspiration of the contents with local instillation of antibiotics and thorium dioxide (Thorotrast),[7] leading to decompression and subsequent shriveling of the capsule; if x-ray studies show unsatisfactory progress, craniotomy and excision is then performed.

The other method, introduced by Vincent[8] for the well-encapsulated abscess and subsequently extended by LeBeau,[9] Fincher,[10] Schwartz and Roulhac[11] and Meirowsky and Harsh[12] to cover the more acute varieties, consists in primary excision regardless of the stage of evolution, followed by tight closure without drainage, associated in the past 14 years with local and systemic antibiotics. The latter method has been the method of choice in this center.

The advantages derived from this method are an immediate and lasting decompression on excision of the abscess and the removal of the stimulus to edema with consequent relief of brain stem pressure. Furthermore, the possibility of recurrence due to untapped daughter abscesses is reduced, the period of hospitalization is considerably shortened, and repeated x-ray studies and taps are not required.

The objection, which has frequently been directed at this method of treatment, that excision, particularly in the stage of acute cerebritis, leads to greater permanent neurological deficit finds no confirmation in this series in which excision produced no greater deficit than aspiration, though comparisons are exceedingly difficult to make in view of the numerous factors which must be evaluated in each case, not the least of which are the location of the lesion and the degree of progression attained by the time of operation.

The grave significance of changes in the level of consciousness has been emphasized both as an indication for prompt relief of pressure and as an index to prognosis. Since the problem of postoperative meningitis and local recurrence has been markedly reduced with the use of antibiotics, future improvement in results can be expected to result mainly from earlier diagnosis, particularly before the onset of deterioration in consciousness. This point receives strong support from the fact that only 1 of 10 patients with acute cerebritis and none of the patients who were alert died, whereas 8 of the 27 with chronic thick-walled abscess died.

Insofar as epilepsy is concerned, this continues to be a serious sequel in a high percentage of patients, particularly in the adult group. There is no evidence to suggest that antibiotics have reduced this complication, the incidence being roughly the same as in the days prior to their introduction.

The method of treatment used likewise seems to bear no relation to the development of seizures, since an almost identical incidence of epilepsy (55%) was reported by Gurdjian and Webster[4a] for intraparenchymatous abscesses treated by aspiration or aspiration followed by delayed excision. A recent review of this problem by Northcroft and Wyke[13] in patients treated by aspiration gives a similar incidence.

Conclusions

Cerebral abscesses occur with approximately the same incidence today as prior to the introduction of antibiotics. The gross mortality for this study has been 27% and the operative mortality 22%. In patients showing no alteration in consciousness at the time of operation the mortality has been zero.

Mortality today is related mainly to brain stem compression and is not related to the type of organism or the degree of encapsulation of the abscess.

Postoperative epilepsy is the most frequent sequel of cerebral abscess. It is not related to the type of treatment used. The antibiotics have not reduced the incidence of this complication, and, in this series, no case of epilepsy occurred in the survivors who were in the first decade of life.

Primary excision of the abscess is considered to be the most satisfactory therapy for the following reasons: 1. It provides prompt internal decompression. 2. It permits a careful inspection of the abscess bed and the removal of daughter abscesses which might otherwise be overlooked. 3. It eliminates the need for repeated x-ray procedures and aspirations of the cavity and thus shortens hospitalization. 4. The mortality and morbidity is no greater with excision than with aspiration. Any further reduction in mortality will be the result of diagnosis and treatment before the onset of brain stem compression.

ISONIAZID.—Mycobacterium tuberculosis . . . has suffered a severe buffeting in recent years. Dazed by the attack of streptomycin and harassed by the attentions of para-aminosalicylic acid (PAS), it is now reeling from the blows of isoniazid, the most deadly yet of its chemotherapeutic adversaries. Isoniazid is the hydrazide of isonicotinic acid. . . . It is a white crystalline powder, freely soluble in water and easily absorbed from the gastrointestinal tract. Maximal blood levels are obtained within an hour of ingestion, but effective concentrations are still demonstrable in the blood twenty-four hours after a single dose of 3 mg. per kg. body weight. Ready diffusion into body tissues and fluids occurs, and adequate levels of the drug are obtained in caseous foci (Barclay et al., 1953). Isoniazid diffuses well, whilst streptomycin and PAS fail to do so. It also exceeds streptomycin and PAS in its ability to penetrate cell membranes and can exert its bactericidal effect on bacilli lurking within phagocytes, whereas the intracellular concentration of streptomycin is low and that of PAS non-existent. . . . Whilst the vast majority of the bacilli comprising an isoniazid-sensitive strain are susceptible to very low concentrations of isoniazid, a few mutants inherently resistant to higher concentrations may also be present. Treatment by isoniazid alone eliminates the susceptible organisms but the resistant organisms are unaffected by the drug and may multiply until the strain is predominantly isoniazid-resistant. If isoniazid is used in combination with another anti-tuberculosis agent such as streptomycin, streptomycin will suppress isoniazid-resistant mutants and vice versa. In practice, therapy with two effective drugs in correct dosage almost excludes the possibility of resistant strains emerging, as the likelihood of mutants resistant to both drugs is so small as to be almost negligible.—J. D. Ross, M.B., Current Therapeutics, Isoniazid and Related Drugs, *The Practitioner*, June, 1958.

ABSORPTION OF LOCAL ANESTHETICS

Donovan Campbell, M.D.
and
John Adriani, M.D., New Orleans

Factors that determine the rate of absorption of a local anesthetic were studied in canine and, when possible, in human subjects. The drugs used were tetracaine, cocaine, procaine, and benzocaine. Objective data was obtained in the form of actual concentrations of each drug in the blood, and the concentrations obtained by intravenous injection were compared with those obtained by infusion, infiltration, and topical application under various conditions. The concentrations reached in the blood after intravenous injection were much higher when infusion was rapid than when it was slow. Absorption from the mucous membranes of the pharynx and trachea gave blood concentrations comparable to those attained by intravenous injection. Absorption of detectable amounts occurred from the surface of the abraded skin and skin after third degree burns but not after first or second degree burns. Since it must be assumed that the danger of undesired systemic reactions is greater in proportion to the concentrations reached by the drug in the blood, anyone using local anesthetics should be well informed as to the factors that may hasten absorption.

Reactions from local anesthetics may occur irrespective of the mode of administration. They are, however, most common after topical application. Pharmacological data indicate that most toxic reactions from local anesthetics are associated with high plasma drug levels from rapid absorption. Studies of drug concentration in the blood to support these conclusions are few because methods of analysis have been unsatisfactory. Analytic techniques for determining minute quantities of local anesthetics are now available. A number of methods in use are based on the fact that local anesthetics are amines which form complex colored compounds with dyes, such as methyl orange or bromthymol blue. These derivatives are extracted with chloroform or ethylene dichloride, at the proper pH, and estimated colorimetrically. Woods and associates[1] have used a method based on this principle to study the metabolism of cocaine.

In a previous communication, we presented preliminary data on the absorption of tetracaine from the pharynx and trachea.[2] We have expanded these studies and have determined blood drug levels after the absorption of tetracaine, cocaine, procaine, and benzocaine from the subcutaneous tissues, the abraded and burned skin, and the mucous surfaces of the pharynx, trachea, bronchi, stomach, esophagus, and bladder. These drug levels were compared with those resulting from equivalent amounts administered intravenously. For obvious reasons the greater portion of the study was done in dogs, although parallel clinical studies were carried out whenever possible. This report is a summary of our findings and recommendations.

Drug Levels After Infusion, Infiltration, and Topical Application

Infusion.—Striking differences were noted in blood drug levels resulting from a rapid intravenous injection over a period of one minute and those after the infusion of the same dose slowly over a 20-minute period. The rapid injection resulted in a marked upsweep in the drug concentration to a peak level within two minutes, while after slow infusion the level was barely detectable. The contours of the drug level curves were the same with procaine, tetracaine, and cocaine.

A rapid injection of 6 mg. per kilogram of body weight of tetracaine in dogs produced respiratory paralysis. The slow infusion of the same quantity caused no reaction. A slow infusion allows time for dilution, storage, and perhaps hydrolysis or elimination of a portion of the drug. The susceptible cells are not suddenly perfused with a high concentration of the drug as they are after a rapid infusion. A slow infusion continued indefinitely ultimately causes symptoms of systemic toxicity due to cumulative effects.

Infiltration.—Drug levels in the blood, determinations of which were obtained after cocaine and tetracaine were infiltrated subcutaneously over an area 3 by 4 cm. on the abdomen, were detectable but not measurable. Equivalent quantities combined with hyaluronidase gave peak levels of 2 to 3 mcg. per milliliter with tetracaine and 1 to 2 mcg. per milliliter with cocaine 10 to 20 minutes after infiltration. The hyaluronidase obviously facilitates absorption by promoting spreading over a wider area.

Topical Use.—Blood drug level curves after topical application simulated those of a rapid intravenous injection. The peaks were lower, took long-

Read before the Section on Anesthesiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

er to develop, and did not rise as abruptly, however. Within four to six minutes the peak was one-third to one-half that of a rapid intravenous injection when an equivalent dose was applied to the pyriform fossae.

Fractional Versus Single Applications: Many reactions which occur after the topical use of local anesthetics are caused by the application of too much at one time. Drug levels in the blood were lower when a given dose of a drug was applied to the pyriform fossae in three fractions at three-minute intervals instead of at one time. The peak levels were approximately one-third those obtained after a single application and rose and fell with each application. The contours of the drug level curves were alike for both cocaine and tetracaine. The levels, even though lower than those with intravenous administration, were measurable and greater than those obtained after infiltration or slow infusion.

Effect of Varying the Concentration.—Blood drug levels are a function of the total dose and not the concentration of the solution used. The levels were similar when the same number of milligrams of tetracaine was applied over identical areas with use of either a 2% or a 4% solution. The same was found to be true when cocaine was used as a 4% and as a 10% solution.

Absorption from Particular Areas

Absorption from the Pharynx, Trachea, and Lungs.—The rate of absorption is not the same from all mucous surfaces. Absorption is more rapid from the trachea than from the pharynx. Instillation of cocaine and tetracaine into the trachea gave higher peak levels, a steeper slope, and a more rapid build-up than application to the pharynx. Higher levels and steeper curves were obtained with the animals in the upright position than in the prone. The solution obviously gravitates into the alveoli, from which it is more rapidly absorbed. Finely nebulized cocaine is rapidly absorbed when inhaled.

Absorption from the Stomach and Esophagus.—The absorption rate from the epithelium of the respiratory tract differs from that of mucous membranes elsewhere. Woods and associates [1] reported no significant blood drug levels after instilling cocaine into the stomachs of dogs. Steinhaus,[3] using the pharmacological approach, concluded that there is no appreciable absorption from the mucous membranes of the esophagus and stomach. These findings appear startling since they are contrary to what one would expect. However, we likewise obtained no detectable drug levels after instilling tetracaine and cocaine into the stomach or esophagus. Several possible explanations may be offered for the apparent lack of absorption from the stomach: Many drugs are poorly absorbed from the stomach. Perhaps local anesthetics follow this pattern of behavior. Perhaps the drug is rapidly destroyed as it passes through the liver, which it must do if absorbed from the gastrointestinal tract. Further studies are needed before this question is answered.

Absorption from the Bladder.—No blood drug levels could be demonstrated after instillation of either tetracaine or cocaine into the bladder. This is a reasonable finding since few drugs pass through the bladder's mucous surface. Our data after urethral instillation were inconclusive. No drug concentration in the blood was demonstrable. However, reactions are common after the urethral instillation in human beings. How many of these reactions are due to absorption from a mucosa traumatized by instrumentation is difficult to say, since this appears as a frequent complicating factor.

Absorption from Abraded and Burned Skin.—Local anesthetics are not absorbed from the unbroken skin. They do pass into the blood if the skin is abraded. Measurable drug levels in the blood were obtained when aqueous solutions of tetracaine, cocaine, procaine, and ointments of cocaine, tetracaine, and benzocaine in a water soluble base were applied to the skin over the abdomen which had been freshly abraded. Peak drug concentrations of the magnitude obtained after infiltration resulted within 6 to 10 minutes.

Blood Levels After the Use of Ointments.—Aqueous solutions of cocaine and tetracaine and ointments of tetracaine and benzocaine were applied to areas of skin burned in varying degrees. No detectable drug levels were obtained after application to first or second degree burns. If the vesicles remained intact and there was no raw surface, detectable drug concentrations were not obtained in cases of third degree burns.

Applications were made immediately and at intervals of 6 to 48 hours after burning. Application of the drug to the raw surfaces after opening the vesicles gave detectable drug levels in the blood. No absorption occurred after application to the eschar of an old burn. However, when the eschar was removed and the drug applied to the raw area, the blood drug levels were measurable. Thus, local anesthetics should be applied cautiously to raw, granulating surfaces.

Influence of Vasoconstrictors

The effectiveness of vasoconstrictors in retarding absorption of local anesthetics is well recognized. The systemic toxicity of procaine after infiltration is reduced 30% or more by the addition of a 1:100,000 concentration of epinephrine hydrochloride to the solution. Spinal anesthesia may be prolonged as much as 60% by adding epinephrine to the solution used for spinal anesthesia. Other vasoconstrictors retard absorption, but none is as effective as epinephrine. Phenylephrine (Neosynephrine) hydrochloride and cobefrine (Corbasil) are not as effective and require much larger doses to produce vasoconstriction. Arterenol is nearly as effective as epinephrine but is not used because of the possibility of slough.

Since vasoconstrictors are effective for infiltration, nerve blocking, and spinal anesthesia, it is not unreasonable to assume that they are also effective in retarding absorption from mucous membranes. This, however, is not the case. The differences in blood drug levels after the application of tetracaine and cocaine to the pyriform fossae and the trachea with and without epinephrine were not significant. After preliminary spraying with epinephrine and arterenol in sufficient quantities to cause blanching of the mucous membranes, drug levels, after the application of both drugs, were nearly the same as those of the controls.

Vasoconstrictor Effect of Cocaine.—Cocaine differs from other local anesthetics in possessing a vasoconstrictor action. Otolaryngologists utilize this properly to "shrink" the nasal mucous membranes. The belief is widely circulated that the more concentrated (10%) solutions of cocaine cause fewer systemic reactions than the dilute solutions (4 or 5%) because they produce a more intense vasoconstriction and, therefore, greatly retard absorption. This assumption is based on conjecture rather than on fact. Blood drug levels after the application of identical weights of cocaine as a 4% and as a 10% solution to areas of identical size in the pyriform fossae were similar.

Effect of Premedicants

Premedication with atropine supposedly retards absorption because the mucous membranes are dry. Curves of levels of cocaine and tetracaine after pharyngeal instillation were the same whether atropine had been used for premedication or not. Barbiturates, likewise, do not influence absorption. Drug concentration curves were identical in studies of anesthesia induced with secobarbital (Seconal) and in studies done without anesthesia.

Absorption of the Basic Form

Local anesthetics are organic bases (amines) which form salts with acids. The bases are, comparatively speaking, insoluble in water. The salts are employed because they are more soluble and stable. Alkaline substances precipitate the free bases from aqueous solutions of salts. A suspension of cocaine base, known as "cocaine mud" has been used topically with the reasoning that the drug gives longer anesthesia and fewer reactions because it is slowly absorbed and remains in contact with tissues longer.

Our studies indicate that the free bases are absorbed almost as rapidly from mucous membranes as are the salts. Detectable blood drug levels were found after tetracaine and cocaine base suspended in water were applied to the mucous membrane of the pyriform fossae. The drug levels were slightly lower than those obtained when the hydrochloride was used. They were not detectable when the drugs were incorporated in oily ointment bases. The basic form is more soluble in oils than in water and is, therefore, absorbed slowly. However, the cocaine and tetracaine base and benzocaine incorporated in a water soluble ointment base applied to the mucous membranes gave drug levels similar to those resulting from applications of aqueous suspensions. Obviously, the bases are easily and freely absorbed. This has practical significance in the use of ointments in the anorectal areas.

Considerations in Induction Anesthesia

Period of Latency.—An overlooked, important, and often disregarded property of local anesthetics is the period of latency after application of the drug. This varies with each drug and with the technique of application, the site of application, and the total dose. The longer-lasting drugs have, comparatively speaking, longer latent periods. The period of latency is shortened by increasing the concentration and the total dose.

Operators who apply the drug and immediately commence instrumentation usually find anesthesia inadequate. They then apply additional fractions before the effect of the first application has become established. This practice often leads to overdosage and systemic intoxication. With the exception of benzocaine, the latent period of most topically applied local anesthetics exceeds five minutes. Therefore, sufficient time should be allowed for the establishment of anesthesia before more of the drug is added.

Status of the Patient.—The relationship of the metabolic state of the patient to the response to local anesthetic is seldom considered when these drugs are used for surgical anesthesia. Fever, dehydration, electrolyte imbalance, pulmonary insufficiency, and cardiovascular disease may be important modifying factors. Endoscopic procedures, as a rule, are performed with use of topical anesthesia. Bronchoscopy, for example, is frequently performed in patients with pulmonary insufficiency. During the instrumentation, ventilation is often decreased. This, in turn, affects circulation. Mild degrees of overdosage which are easily tolerated by patients who are good risks may terminate fatally in the poor-risk patient.

Limits of Dosage.—The most important precaution to be followed to avoid reactions is to limit the dose. It is impossible to designate limits of dosage of local anesthetics, because such limits vary from individual to individual and even in the same individual at different times, depending on the general state of the subject at the time. Recommended doses for newly introduced drugs are often based on lethal doses in animals. Doses of older, well-established drugs are based on impressions derived from clinical experience. Procaine is the standard for comparison of toxicity and potency of local anesthetics. Most regional anesthetists limit the dose of procaine for perineural injection or infiltration to 1 Gm. at any one sitting. Therefore, 50 cc. of a 2%, 100 cc. of a 1%, or 200 cc. of 0.5% solution are the maximum volumes to be injected. Tetracaine is approximately 10 times more potent and toxic than procaine. The maximum dosage, with procaine used as the basis of comparison, would be 100 mg. for infiltration or perineural injection. Piperocaine (Metycaine) hydrochloride is slightly more potent and toxic than procaine; therefore, 1 Gm. should be the limit. Lidocaine (Xylocaine) hydrochloride is twice as potent and twice as toxic as procaine; therefore, 0.5 Gm. is considered the limit. Hexylcaine (Cyclaine) hydrochloride and chloroprocaine (Nesacaine) hydrochloride are like procaine and, therefore, are not used in quantities exceeding 1 Gm.

This reasoning cannot be applied to the use of these drugs topically because the rate of absorption, the extent of the area to which the drug is applied, and the type and vascularity of the mucous membrane in question are so variable. Procaine is not effective topically and cannot be used as a basis for comparison. Comparisons of duration of action are usually made with cocaine as the standard. Comparative doses of cocaine and other topical anesthetics for man are not available. From the cases we have studied most difficulties seem to have arisen when one-fourth to one-third of the limit recommended for infiltration has been exceeded topically. We wish to point out that quantities less than this may cause reactions in some patients, because an arbitrary rule such as this cannot take into consideration individual susceptibility, intolerance, and the technique of application.

Use of Sprays.—The mode of topical application is often debated. Some anesthetists are opposed to the use of sprays. It is impossible to adequately anesthetize the nasal and pharyngeal mucosa without nebulizing the solution. Thus, it is virtually impossible to do without a spray. Careless use of a spray may, however, lead to overdosage. Few sprays are designed specifically for topical anesthetization. A spray suitable for local anesthesia should deliver particles as nearly uniform in size as possible. Generally, particles less than 30 μ in diameter form a mist which diffuses into the alveoli where they are quickly absorbed. Larger particles coalesce into a film which coats the pharynx and tracheobronchial tree. Coarse particles unite to form drops which pool in the upper pharynx and trickle into the trachea, from which the solution is rapidly absorbed. Therefore, a spray should be selected which delivers particles of a uniform size, neither too large nor too small. A "microspray" devised by Carabelli,[4] for instance, delivers a mist which lodges in the nose, pharynx, and trachea. Approximately 25 squeezes of the bulb are required to deliver 1 cc. of fluid. The sprays used to vaporize solutions of vasopressors for the treatment of nasal disorders are inadequate because they deliver large volumes of mixtures of particles of all sizes, both fine and coarse. In some cases one squeeze of the bulb delivers approximately 1 cc. of fluid. The use of such sprays sooner or later leads to overdosage.

Intolerance and Allergy.—One must not infer from this discussion that every reaction from a local anesthetic is due to overdosage. Intolerance, hyperergy, and allergy do occur, and, therefore, they should not be discounted as a possible cause of reaction. They do, however, occur far less frequently than is alleged. Overdosage leads by far as the causative mechanism of reactions after the use of local anesthetic drugs.

"Caine" Versus "Non-Caine" Drugs

The suffix "caine" appended to the name of a drug usually indicates that the compound is a local anesthetic. The suffix does not necessarily designate a particular chemical or pharmacological type of drug. It has been used to name compounds which are qualitatively similar to procaine and cocaine in pharmacological behavior. Certain pharmaceutical companies have been referring to local anesthetics in their advertising as not a "caine" type of drug, with the inference that the "caine" drug is a specific type which is deleterious, more toxic, or allergenic. Whether a drug is a "caine" or "non-caine" type is merely a matter of nomenclature. Nomenclature is not a criterion of toxicity or allergenic properties. Sensitization may occur from many varieties of drugs—local anesthetics included. These qualities are not peculiar to local anesthetics or to the local anesthetics whose names end in the suffix "caine." One therefore must be guided by all the biochemical and pharmacological data on hand in assessing the worth of a drug.

Conclusions

The majority of reactions from local anesthetics are due to high plasma drug levels from the use of excessive quantities or rapid absorption. Reactions are more common after surface application than after injection. Absorption from the mucous membranes of the pharynx and trachea results in drug levels comparable to those with intravenous injection. Absorption is more rapid from the trachea than from the pharynx. Absorption is a function of total dosage rather than of concentration. Drug levels in the blood after the topical application of equivalent weights of cocaine as 10% and 4% solutions are nearly alike.

Vasoconstrictors, such as epinephrine and arterenol, do not retard absorption from the mucous membranes. They are, however, effective in retarding absorption after perineural or subcutaneous injection. The vasocontrictor effect of a 10% solution of cocaine is no more effective in retarding absorption than the 4% strength.

Detectable drug levels in the blood are obtained after application of local anesthetics to broken and abraded skin and from the raw surfaces of third degree burns. There is no absorption from the second degree or first degree burns.

Local anesthetics incorporated in water soluble creams are absorbed from the mucous membranes. Absorption is poor if the drug is incorporated in an oily medium. Aqueous suspensions of the crystals give detectable drug levels when applied to the mucous membranes. Hyaluronidase facilitates the absorption of injected local anesthetics but has little influence on absorption in surface application.

Anyone proposing to administer a local anesthetic should be throughly familiar with the pharmacological behavior of the drug employed and be prepared to deal quickly with untoward reactions which may develop.

PROBLEM OF THE RUPTURED DIAPHRAGM

Philip E. Bernatz, M.D., Alfred F. Burnside Jr., M.D.
and
O. Theron Clagett, M.D., Rochester, Minn.

A high index of suspicion on the part of the physician is the most important factor in diagnosing ruptured diaphragm. Clinical manifestations in this series vary from no symptoms to life-endangering problems immediately after the injury. The presence of extraneous shadows above the diaphragm, such as gas-containing or homogeneous areas, along with a shift of the mediastinal structures away from this side, is extremely suggestive of a ruptured diaphragm. Of 112 patients who received surgical treatment for a ruptured diaphragm, 78 incurred the injury in automobile accidents. Transthoracic repair of the ruptured diaphragm is recommended as early as the patient's condition permits.

A total of 112 patients have received surgical treatment at the Mayo Clinic for a ruptured diaphragm. Of these, 78 incurred the injury in automobile accidents. With the casualty lists mounting from highway travel, no statistical manipulation is required to augment the conclusion that the patient with a ruptured diaphragm is not a "thing of the past." Physicians in every community undoubtedly can anticipate the management of such patients.

Definition and Etiology

The problem in these 112 cases was loss of anatomic continuity of the diaphragm of variable extent, with the passage of some of the abdominal contents into the pleural space. No cases were included in which the herniation of abdominal viscera was through the esophageal hiatus, and a hernial sac was never present in this series. Harrington[1] previously reported 67 of these 112 cases. Seven patients gave histories of some inflammatory process, such as a subphrenic abscess or empyema, after an operation or a penetrating injury. As already mentioned, significant trauma in an automobile accident was present in 78 instances. Another common form of injury was blunt trauma, such as crushing pressure by overturned farm machinery or a fall from a height of many feet. Penetrating injuries as a result of gunshot or stab wounds accounted for a few cases. Iatrogenesis was apparent in one case. With the increasingly casual incision of the diaphragm in operative approaches of one kind or another, one might anticipate an increase in the number of such cases. A history of previous injury could not be elicited in four patients, suggesting that the trauma required to rupture the diaphragm need not be severe.

Read before the Section on Surgery, General and Abdominal, at the 107th Annual Meeting of the American Medical Association, San Francisco, June 27, 1958.

Clinical Manifestations

The patients ranged in age from 1 to 80 years, the average being 35 years. There were 92 males and 20 females. The defect was on the left side in 104 cases and on the right in 8. Bilateral rupture, such as reported by Manlove and Baronofsky,[2] was not encountered, although multiple defects on one side were observed.

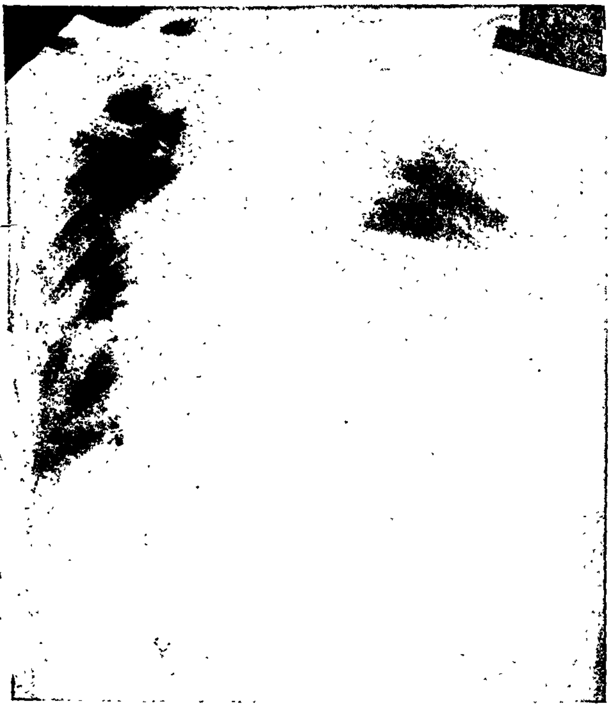

Fig. 1.—Distended abdominal viscera in left thorax, with llapse of left lung, shift of mediastinum, and compression f right lung.

The symptoms varied consistently, which suggested a useful grouping within the series. This appeared reasonable, since the problems of management were significantly different in each group. Group 1 included patients who did not have symptoms. Group 2 comprised those with prolonged gastrointestinal or respiratory complaints, usually not severe and often considered functional in origin. Group 3 included patients with symptoms similar to those in group 2 but who also had some acute complication, such as intestinal obstruction. Group 4 was made up of those with severe, life-endangering problems immediately after the injury.

Group 1.—Group 1 included six patients who had no symptoms and whose diaphragmatic defects were noted on routine thoracic roentgenograms.

Group 2.—The 91 patients in group 2 made up the great majority of the series. Their stories were remarkably consistent, in that after a mishap, often an automobile accident, in which injuries of varying severity were sustained, upper abdominal distress aggravated by eating was noticed. Discomfort often was referred to the left shoulder, especially when a reclining position was assumed in the hope this would relieve the distress. The main complaints were gastrointestinal in half of the patients. About 25% noted dyspnea and peculiar sensations in the thorax. In another 25% the main complaint was pain, usually in the left upper quadrant of the abdomen and left lower part of the thorax, sometimes cramping but occasionally pleuritic, often referred to the left shoulder, and aggravated by the ingestion of meals. Gastrointestinal bleeding was noted in only three patients; this was not massive.

Group 3.—The nine patients in group 3 had chronic symptoms similar to those of the patients in the second group but were forced to seek medical attention because of acute symptoms from obstruction of the gastrointestinal tract at any point from the distal portion of the esophagus to the descending colon. Such an occurrence was weeks to years after the original injury. Lack of abdominal distention in these cases was deceiving initially.

Group 4.—Only six patients comprised group 4, but in many respects they provided the most challenging problems of diagnosis and treatment. These patients were in desperate trouble within a few hours after injury, largely because of deranged cardiorespiratory function precipitated by the presence of distended abdominal contents in the pleural space (fig. 1). In addition, these patients had severe associated injuries.

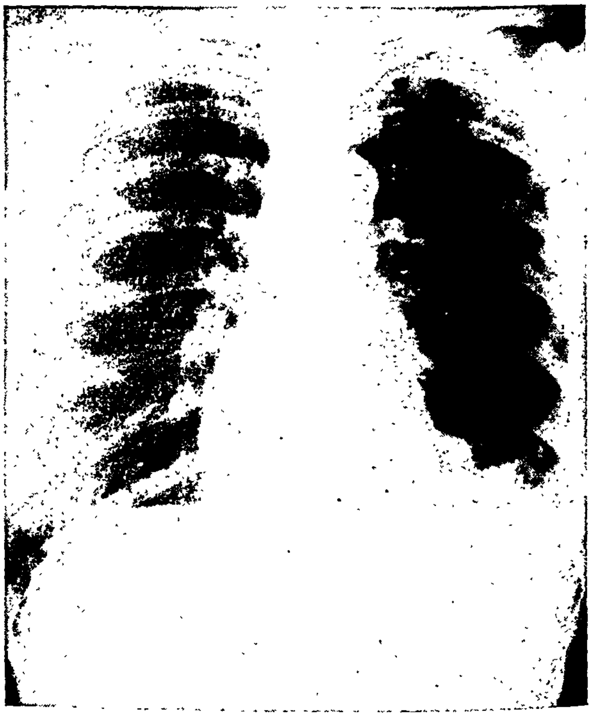

Fig. 2.—Extraneous gas shadow above normal level of left diaphragm, with slight movement of mediastinal structures to right.

Diagnosis

The clinical story in a large percentage of these 112 patients was almost diagnostic. The plain thoracic roentgenogram often was interpreted as revealing eventration of the diaphragm. The presence of extraneous shadows above the diaphragm, such as gas-containing or homogeneous areas, along with a shift of the mediastinal structures away from this side was extremely suggestive of a ruptured diaphragm (fig. 2). Discoid collapse of the lung adjacent to these extraneous shadows was occasionally evident. Passage of a tube through the nose into the stomach prior to thoracic roentgenography is a simple and valuable method for demonstrating the presence of the stomach in the thorax (fig. 3). The use of contrast medium given by mouth or in an enema indicated the diagnosis in a majority of patients, although this is often not necessary and, indeed, may be contraindicated in acutely ill patients with intestinal obstruction (fig. 4). Pneumoperitoneum was used in only one patient.

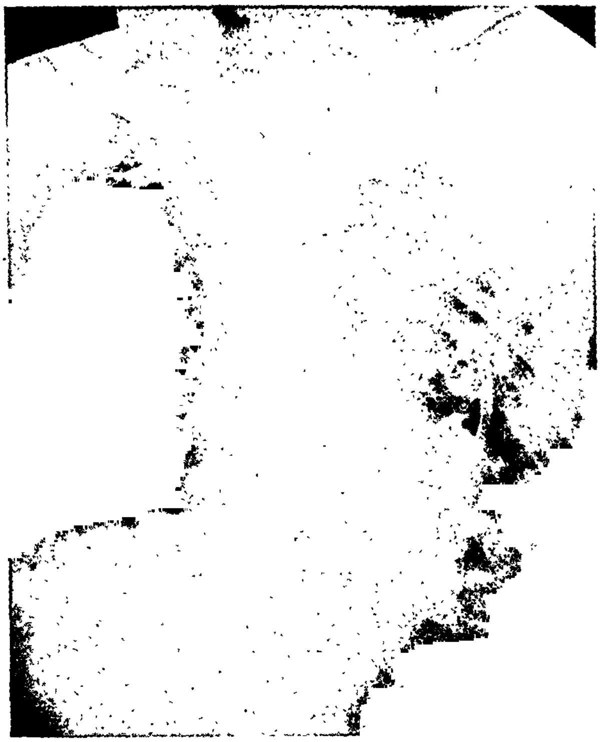

Fig. 3.—Use of gastric tube to confirm diagnosis of ruptured diaphragm.

Operative Findings

The sites of disruption of the diaphragm did not have any consistent anatomic location. We were unable to correlate the ruptures with any theoretical anatomic weakness. The central tendon was often intact, with the tear circumventing this more sturdy portion or radiating peripherally from its borders, but it was not immune from traumatic laceration. The rents varied in length; some were a few centimeters long, and some extended across the entire left leaf of the diaphragm and into the right side. Such tears usually traveled anterior to the esophageal hiatus, with its crura remaining intact, but the crura actually were torn in 11 instances. In three cases, the tear involved the pericardium but cardiac tamponade did not occur. The diaphragm in eight cases apparently was torn completely from the anterior or lateral thoracic wall.

The omentum has the greatest propensity for traversing a diaphragmatic defect into the pleural space, but it seldom was seen as an isolated structure above the diaphragm. The omentum and a portion of stomach or colon were the most common occupants of the thorax, but small intestine, spleen, the tail of the pancreas, liver, and even adrenal and kidney frequently found their way into the thorax.

The left lower lobe was not aerated at the time of operation in a number of patients, but it was not necessary to decorticate the lung in a single instance to reexpand the lung adequately. In consideration of the usual trauma, it is surprising that the spleen seldom presented evidence of capsular damage; splenectomy was done in only two instances. Adherence of viscera to the edges of the defect usually was present in the patients whose injuries were not recent, but it was interesting to note how few adhesions were present between viscera in the pleural space. Pronounced dilatation and hypertrophy of the walls were noted in the thoracic stomachs, some of which were described as four to five times normal size. Although stomachs may be equally large in some cases secondary to acute gaseous or fluid distention, it can be speculated that

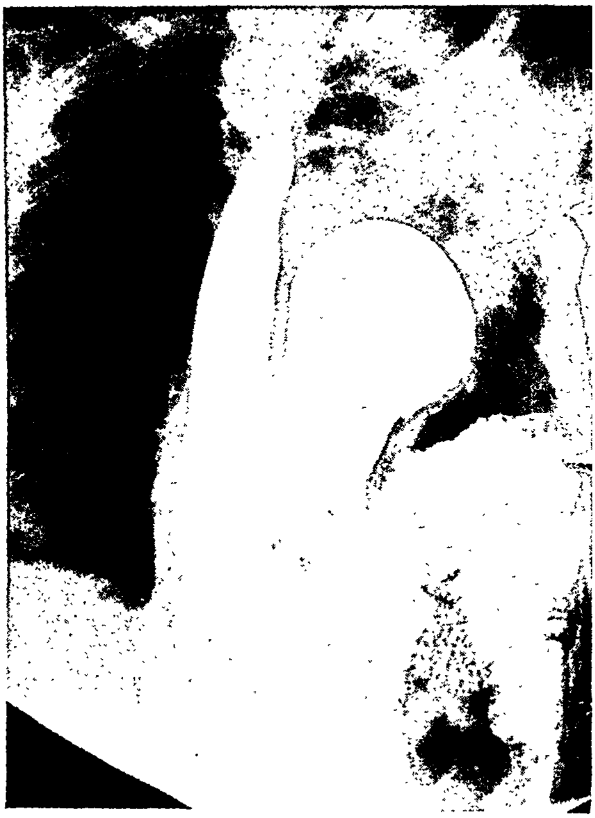

Fig. 4.—Use of contrast medium to demonstrate presence of stomach and small intestine in thorax.

chronic partial obstruction and functional derangement led to these hugely dilated stomachs. This was true, in isolated instances, of the colon and small intestine as well. Interesting, but less common, findings were strangulation of a portion of the stomach, stricture at the esophagogastric juncture where the tomach turned abruptly around an intact esophageal hiatus into the thorax, and perforation of the esophagogastric junction with formation of abscesses.

Treatment

Repair was accomplished by the abdominal route in 75 cases, whereas it was done transthoracically n 34 cases and thoracoabdominally in three cases. Four patients died in the immediate postoperative period, resulting in a hospital mortality of 3.6%. The phrenic nerve was crushed in 67 of the earlier cases: The undesirable effects of such a maneuver now are considered to outweigh its possible benefits, and this is no longer done. At the present time, approach through a thoracic interspace is utilized. This technique permits accurate freeing of adherent structures and reapproximation of the freshened edges of the diaphragm with two rows of interrupted nonabsorbable sutures. Reinforcement of the suture line with a strip of fascia lata was used to advantage in many cases but has not been included in recent repairs; results appear to justify its omission.

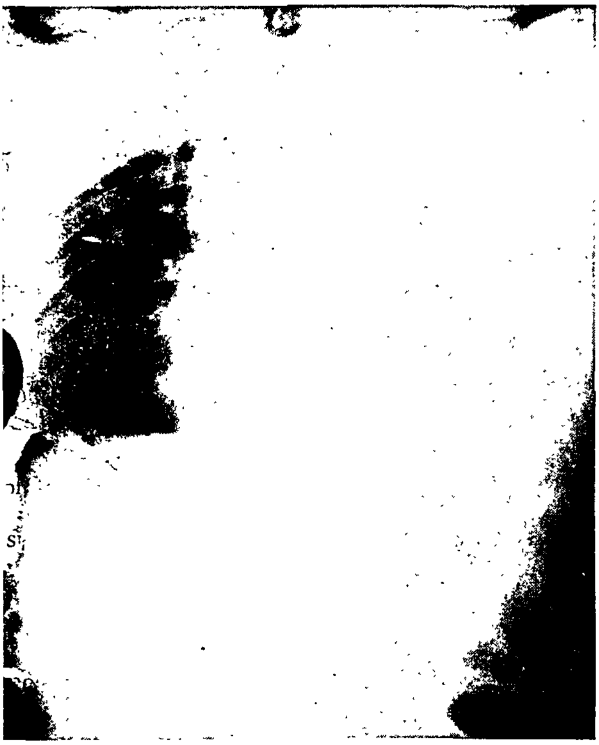

Fig. 5.—Obstruction caused by torsion at esophagogastric junction, making decompression of stomach by tube impossible.

In contradistinction to the simple technical management in the usual case, certain diaphragmatic reconstructions may present major problems. If the diaphragm has been torn from the rib cage and time, with its resulting atrophy, has erased previously existing remnants, the surgeon may be forced to such maneuvers as partial thoracoplasty, elevation of prerenal fascia, suture of the capsule of the liver to the periphery of the defect, or employment of a plastic prosthesis, such as Dacron or compressed Ivalon. Disruption of the musculature forming the esophageal hiatus, such as occurred in 11 cases, requires careful reconstruction. In this medial zone, use of a flap of pericardium, as suggested by Brookes,[3] may be useful in the repair.

When simple or complicated gastrointestinal obstruction is associated with this injury, the intestine must be handled as it is on any other occasion. It is important that dilated intestine not be forced into the abdomen, making it difficult to repair the diaphragm and reducing the chances of a good result. The intestine should be decompressed by enterostomy and suction. With reasonable precautions and maintenance of pulmonary expansion postoperatively, the possibility of infection in the pleural space is minimized. As mentioned previously, these patients often have severe associated injuries, and one may have to use a separate abdominal incision or cross the costal arch to manage certain intra-abdominal injuries. Similarly, other thoracic injuries may be present; in one patient, a "flail chest" was immobilized at the time the diaphragmatic rupture was repaired.

Comment

Years often pass between the rupture and the surgical repair of the diaphragm; the average interval was four and one-half years in these 112 patients. From a practical standpoint, this prolonged interval could present real problems with respect to financial compensation by insurance companies or responsible parties. In another practical way, the resulting atrophy of remnants of the diaphragm sometimes caused technical problems of repair that probably would not have existed had repair been done shortly after the accident. Cardiorespiratory and gastrointestinal complications would have been avoided. Carter and associates[4] pointed out that 90% of strangulated diaphragmatic hernias are traumatic in type. These are all good reasons for advocating early repair of ruptured diaphragms.

The management of the patient with a ruptured diaphragm and severe associated injuries needs careful evaluation in regard to which condition takes precedence for treatment. With simple measures directed at decompression of the gastrointestinal tract and expansion of the lung, the diaphragmatic injury may be handled conservatively and repaired when the patient's condition permits. However, decompression may not be possible (fig. 5), and even the "frowned upon" technique of inserting a trocar into the distended viscera transthoracically may improve the patient sufficiently to permit induction of anesthesia, surgical decompression, and repair of the diaphragmatic defect.

Diagnostic methods are relatively simple and do not require complicated equipment or expert interpretation. A high index of suspicion on the part of the physician is obviously most important. Transthoracic repair of the diaphragmatic rupture is usually a relatively straightforward and effective procedure. With the average age of the patients in our series being 35 years, it is apparent that one usually has the advantage of treating a patient who otherwise is in good health. Severe associated injuries sometimes militate against an extremely low mortality, but a ruptured diaphragm itself need not lead to fatal complications.

Summary

A total of 112 patients with ruptured diaphragm have been surgically treated at the Mayo Clinic. Of these ruptures, 104 were on the left side and 8 on the right. Clinical manifestations in this series varied from no symptoms to life-endangering problems immediately after the injury; however, the average duration of chronic gastrointestinal and cardiorespiratory complaints was four and one-half years.

The diagnosis of a ruptured diaphragm can be accurately made with simple techniques. Transthoracic repair of the ruptured diaphragm is recommended as early as the patient's condition permits. Temporary conservative management of the defect may be reasonable in the presence of associated severe injuries, which are important in the hospital mortality in this group of patients.

CLINICAL IMPORTANCE OF URETERAL DUPLICATION AND ECTOPIA

Ian M. Thompson, M.D.
and
Arjan D. Amar, M.D., Ann Arbor, Mich.

Among the urologic patients admitted to a university hospital the incidence of duplication of the ureter has been 6%. The vesical orifice of the ureter has often been found to lie outside the vesical trigone, and such ectopia in every case has been concomitant with ureteral duplication. These anomalies are associated with much functional disturbance. Infections or other serious disease conditions were present in more than 40% of the cases. Incontinence of urine is not always noted. The patient may be continent even when the ectopic ureteral orifice is in the vulva. One patient with two extravesical orifices did not have urinary leakage until the age of 20, after the birth of her first child. The frequency of these anomalies and the variety of symptoms they produce indicate that they should be kept in mind wherever the physician is confronted with obscure urinary complaints.

Perhaps the most prevalent of genitourinary anomalies is the variety of divisions or segmentations of the conduit system which comes under the heading of ureteral duplication. Commonly categorized as unilateral [illegible]ilateral, partial or complete, duplication relates to a plurality of collecting system occurring below the level of the ureteropelvic junction. Above this point it is referred to simply as a bifid or trifid pelvis (fig. 1). Ureteral ectopia, so frequently a consequence of duplication, pertains to orificial placement in other than a trigonal position.

Embryology

To understand the nature of the aberrations which may be encompassed by ureteral duplication, and especially in considering ureteral ectopia, both normal and digressive embryologic factors must be clarified for the manifold pathological implications to be fully appreciated. In the third and fourth

CLINICAL IMPORTANCE OF URETERAL DUPLICATION AND ECTOPIA

Ian M. Thompson, M.D.
and
Arjan D. Amar, M.D., Ann Arbor, Mich.

Among the urologic patients admitted to a university hospital the incidence of duplication of the ureter has been 6%. The vesical orifice of the ureter has often been found to lie outside the vesical trigone, and such ectopia in every case has been concomitant with ureteral duplication. These anomalies are associated with much functional disturbance. Infections or other serious disease conditions were present in more than 40% of the cases. Incontinence of urine is not always noted. The patient may be continent even when the ectopic ureteral orifice is in the vulva. One patient with two extravesical orifices did not have urinary leakage until the age of 20, after the birth of her first child. The frequency of these anomalies and the variety of symptoms they produce indicate that they should be kept in mind wherever the physician is confronted with obscure urinary complaints.

Perhaps the most prevalent of genitourinary anomalies is the variety of divisions or segmentations of the conduit system which comes under the heading of ureteral duplication. Commonly categorized as unilateral or bilateral, partial or complete, duplication relates to a plurality of collecting system occurring below the level of the ureteropelvic junction. Above this point it is referred to simply as a bifid or trifid pelvis (fig. 1). Ureteral ectopia, so frequently a consequence of duplication, pertains to orificial placement in other than a trigonal position.

Embryology

To understand the nature of the aberrations which may be encompassed by ureteral duplication, and especially in considering ureteral ectopia, both normal and digressive embryologic factors must be clarified for the manifold pathological implications to be fully appreciated. In the third and fourth

---

Read before the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

weeks of embryonic life, a budding occurs in the Wolffian duct near its attachment to the cloaca, constituting *the beginnings of the ureteropelvic* conduit system. The ureteral buds extend upward into the developing kidney tissue and distally are gradually absorbed into that portion of the cloaca which will become the urinary bladder. In the course of the development of the ureteral components there is the possibility that more than one bud, *or one ureter, may arise* from the Wolffian duct. Since duplication may occur in either half of the ureter, it is conceivable that the stimulus toward bifurcation may be primarily a ureteral rather than a Wolffian duct idiosyncrasy.

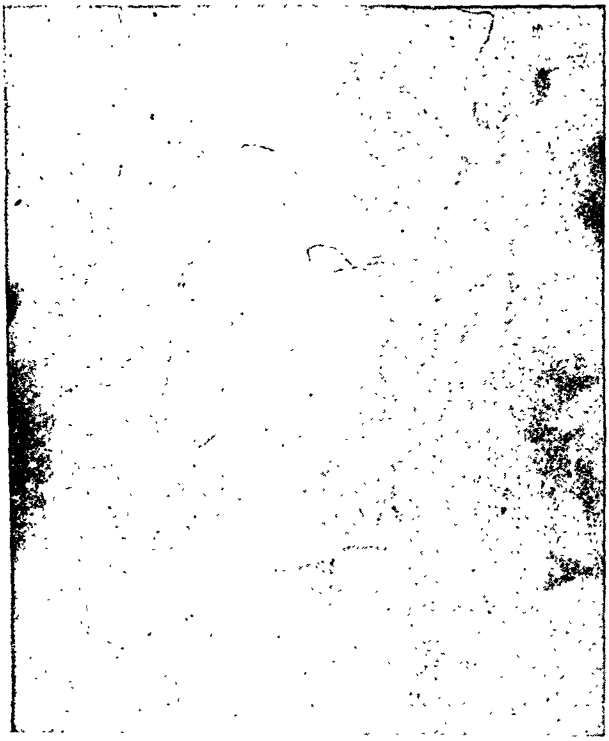

Fig. 1.—Bifid pelvis on right; complete duplication on left.

A few further points are important: Absorption of the ureteral openings into the bladder and the rotation of the kidneys as ascension from the pelvis occurs almost invariably cause the segment of ureter *draining the upper portion of the kidney* to emerge at a point lower in the bladder than the ureter from the inferior pole of the kidney (fig. 2). The normal downward growth of the area where the ureters enter the bladder can thus in cases of duplication be productive of ectopic positions of the ureteral orifices. The close proximity of the Müllerian duct system during the developmental period, coupled with any aberration of ureteral rotation-absorption, may *allow an orifice to be incorporated* into a Müllerian duct and thereby subsequently empty into a uterine tube, uterus, or some portion of the external genitalia. Thus an orifice may drain without bladder sphincter control in the female, producing the distinguishing characteristic *of normal voiding and continual* incontinence. In the male, it is presumably not embryologically feasible for an orifice to migrate to a position outside sphincter control since the external urethral sphincter developes at a later date and thus is immune to the penetration of an ectopic ureter. The ureter may, however, open ectopically into other portions of the male genital tract which derive from the Wolffian duct. In both sexes an intestinal connection may be a later consequence of the embryonic cloacal-ureteral attachment.

Incidence

Duplication has been annotated as occurring in approximately 4 to 6% of the population. At the University Hospital at Ann Arbor, Mich., the urographic incidence has been found to be 6%. Although *ectopia has been reported to occur in* but one-half of 1% of the cases of duplication, more than 75% of ureteral ectopia is reputedly associated with duplication. In our series ectopia was a frequent finding and in all cases occurred in conjunction with duplication.

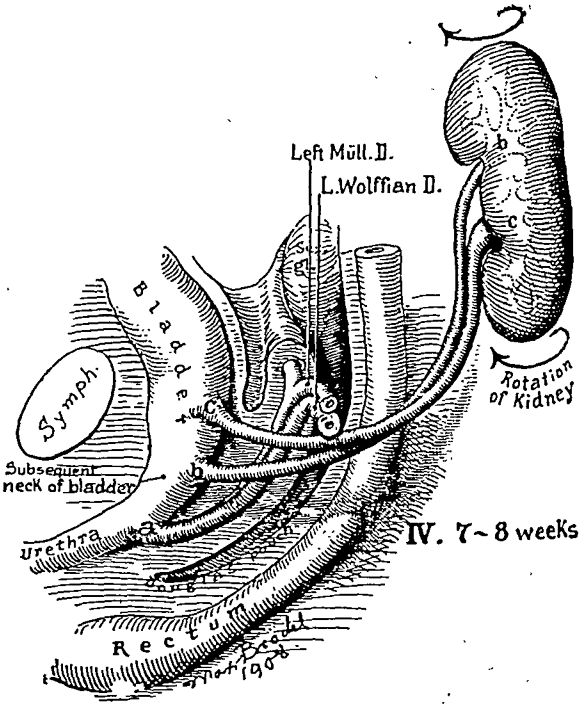

Fig. 2.—Kidney ascension and rotation causing duplicate ureters to cross. Note close proximity of ureteral orifices to Müllerian and Wolffian duct openings.

Frequency of Associated Disease

Ureteral duplication and ectopia would be primarily of academic interest were they not associated with a seemingly inordinate amount of clinical abnormality. At the University Hospital disease concomitance was present in more than 40% of the cases.

Pathological processes which accompany or are associated with duplication and ectopia are due most frequently to the anomalous position of the lower ureteral orifice, even when located within the confines of the bladder. The fact that such orifices open in the region of the vesical neck or urethra, although only rarely productive of loss of control, may occasion sufficient intermittent resistance to permit obstructive potentialities to mature. Similarly, when an orifice is attached to a seminal vesicle, uterus, or uterine tube, back pressure is unavoidable and obstructive consequences may be dramatic (fig. 3). Ectopic ureters so situated as to drain freely to the outside engender harmful effects on the kidney due to easy access of bacterial invaders and the compressive attributes of the structures surrounding the ureter in its ectopic extravesical course.

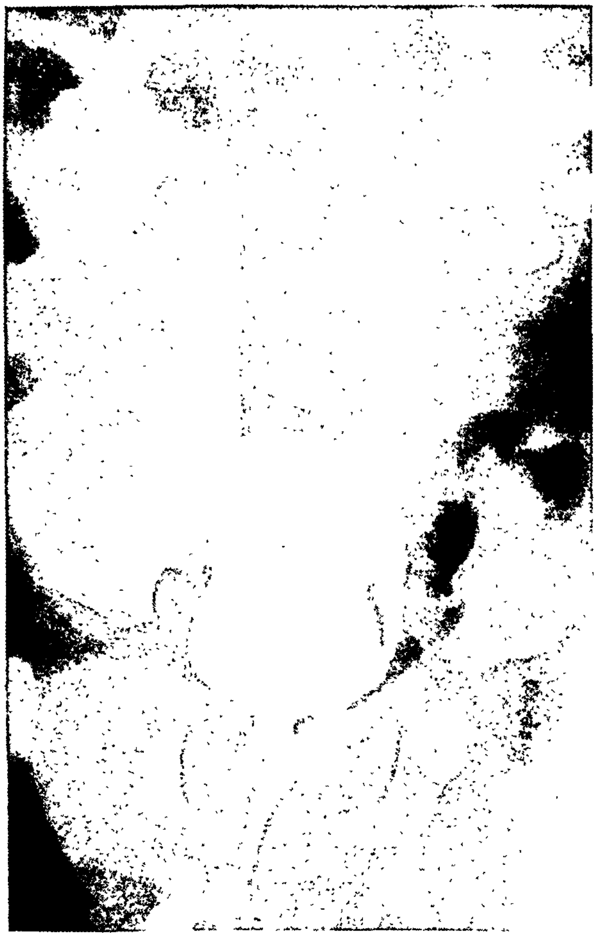

Fig. 3.—Ureters opening ectopically into prostatic urethra occasioning marked hydronephrosis.

The incidence of disease bearing no apparent etiological relationship to the duplicated or ectopic ureter is still much more frequent than can be readily explained by any known mechanism. When the prevalence of incidental abnormality is conjoined with many pathological findings directly attributable to the malpositioned orifices of duplications, the high incidence of disease is better understood and the clinical importance more readily accepted.

Radiographic and Clinical Diagnosis

Certain features referable to the diagnosis of ureteral duplication and ectopia do not appear to be generally appreciated in an analysis of the usual consideration afforded this oftentimes puzzling entity. Perusal of our material has stimulated us to postulate that unrecognized duplications are much more prevalent than is commonly conceded and that they may be responsible for many otherwise inexplicable urinary tract symptoms and signs. To clarify the basis for these postulations, the fact that ureteral duplication usually becomes apparent only subsequent to urographic study must first be recognized. Abnormality may occur in either portion of a duplication, but since the upper segment drains to the lower orifice, which so frequently is malpositioned, it is this upper segment which is more prone to malfunction and radiographic nonvisualization. Thus it is commonly the unvisualized upper segments which become diagnostic problems.

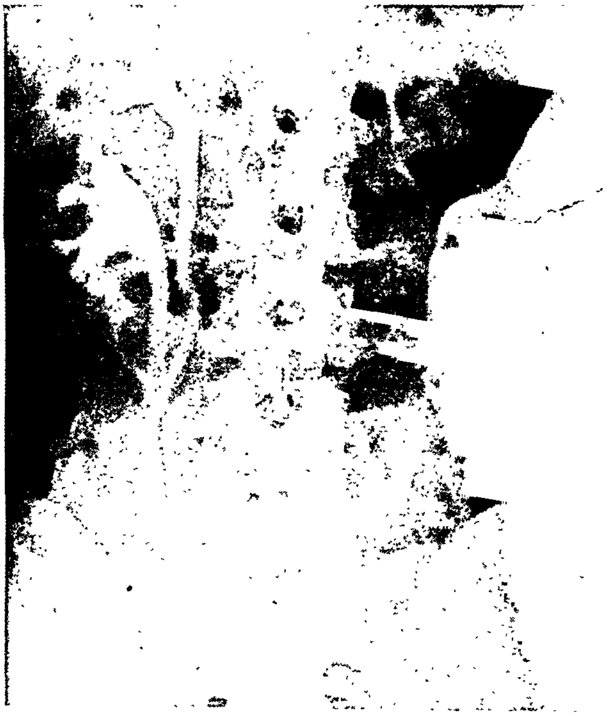

Fig. 4.—Duplication on right; insufficiency of collecting system to upper pole parenchyma and downward and lateral displacement of left pyelogram.

In the absence of the clear delineation of each component of a duplication, certain urographic characteristics have been promulgated as indicative of the presence of an unvisualized segment. First, there is an insufficiency of visible collecting system in relation to the total renal parenchyma, the usual discrepancy being in the supply to the upper pole. Perhaps a more characteristic urographic finding is downward and lateral displacement of the visible collecting system without parenchymal deformity (fig. 4 and 5). Another feature is the lack of an upper major calyx in what otherwise would be construed as a normal collecting system, indicative of the possibility of an unvisualized upper segment which ordinarily would be the upper calyx of a nonduplicated renal conduit (fig. 6). An equivocal sign of unrecognized duplication is a lack of "mirror image" urographic appearance of the two kidneys. Should the pyelographic contours be totally dissimilar, suspicion might be aroused as to the possibility of an unvisualized segment.

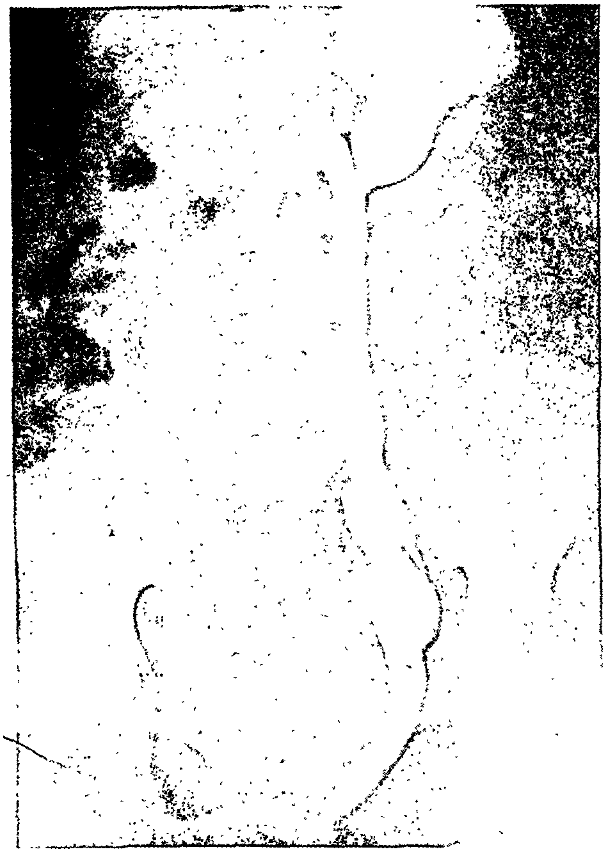

Fig. 5.—Displacement of left pyelogram, caused by marked hydronephrosis in previously unvisualized upper segment. Orifice was ectopic in vulva.

The essential diagnostic picture of ureteral ectopia in female patients has reputedly been urinary incontinence associated with an otherwise normal voiding pattern, whereas in male patients the characteristic features have commonly been those of ureteral duplication. From the clinical point of view it should be apparent that many of the symptoms and signs arising from the pathological consequences of ureteral duplication or ectopia stem from the obstruction or infection so produced and thus are relatively nonspecific in respect to diagnostic import.

The predication that the customary urographic features of nonvisualized ureteral segments cannot be entirely relied on as diagnostic aids is borne out most characteristically in the following two cases: Persistent urinary infection in the presence of normal urograms and a normal bladder had been a frustrating medical travail for a young woman, until a previously unvisualized duplicated segment opening at the vesical neck was discovered (fig. 7). In the other instance, recurring urinary infection ostensibly had been found to derive from a urethral diverticulum. Its situation at the bladder neck had prompted an unroofing rather than an excisional procedure and possibly fortunately so. A complaint of pain in the flank during urination brought the patient to postoperative cystography, demonstrative of reflux up the unsuspected duplicated segment. A subsequent intravenous pyelogram showed return of function after improved drainage to the upper ureter had been established.

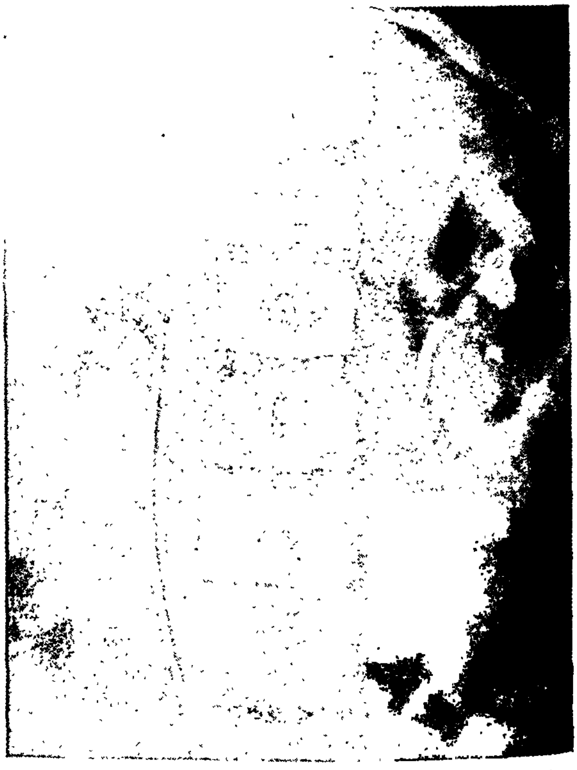

Fig. 6.—Right pyelogram showing no upper major calyx. Catheter is in an unvisualized upper duplicated segment.

In neither of these instances were the customary features of unvisualized duplicated segments present. Yet what we believe to represent an important and hitherto unpublicized characteristic was distinctly apparent: Urographically demonstrable ureteral duplication in one kidney, in the presence of unexplained symptoms and signs of urinary tract disease, suggests the presence of, and makes advisable a thorough search for, an unvisualized duplicated segment in the contralateral kidney.

Similarly in the diagnosis of ureteral ectopia in the female, the most commonly characterized feature—incontinence—may not necessarily pertain. We have seen a woman of 20 years of age with two extravesical orifices who noted urinary leakage only subsequent to delivery of her first child. Figure 8 is referable to a girl who had never suffered incontinence despite a vulvar ureteral orifice. It seems reasonable that compressive effects resulting from the abnormally elongated course of an ectopic ureter through the vesical neck and vaginal septal areas might be coupled with an ingrowth of vulvovaginal epithelial elements to cause plugging by debris and dissuade incontinent leakage of urine. Thus the lack of incontinence may not obviate the possibility of ureteral ectopia in the female.

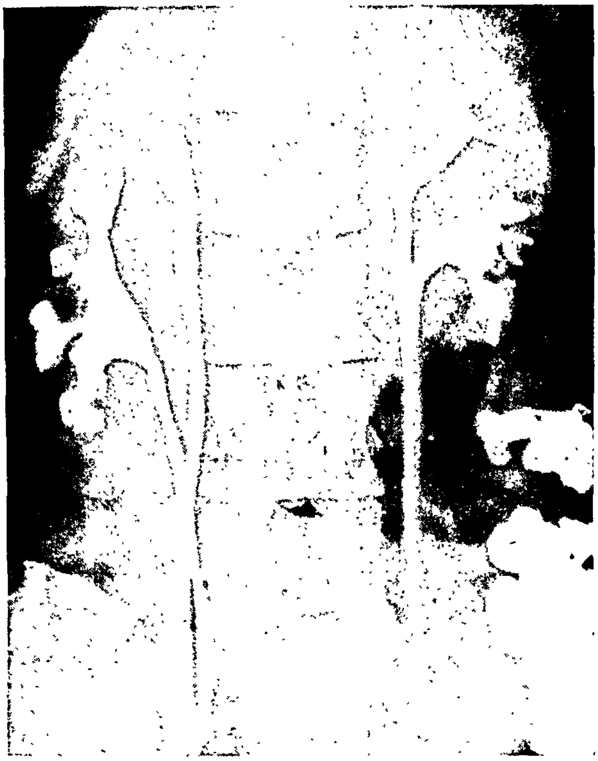

Fig. 7.—Unvisualized right upper segment, causing persistent urinary infection.

Ureteral duplication and ectopia may therefore be suspected not from the radiographic or symptomatic features characterized as diagnostic but from such tangential evidence as has been illustrated: The appearance of a duplication on one side suggesting its presence on the other; an oddly situated urethral diverticulum; or simply the frustration of repetitive, seemingly unwarranted infection being instigative of further search for an unvisualized collecting segment.

How then may unvisualized duplications be more readily diagnosed? The necessity for imprinting the characteristic radiographic and symptomatic findings firmly in the medical mind is of course essential. Equally germane to the urologic evaluation is the need for suspicion of duplication ectopia when urinary symptoms or signs remain seemingly insoluble. The urethra and bladder must routinely be inspected more carefully for a furtive accessory orifice; the insertion of bulb catheters into such openings as may be encountered, with injection of radiopaque material, should be undertaken with greater frequency. Occasionally, only voiding cystourethrograms may delineate unrecognized duplicated segments, since an ectopic urethral orifice may be more readily filled in this fashion; yet the more easily performed retrograde urethrograms can be of equal value in demonstrating ectopia. It would be redundant to emphasize the value of delayed excretory urograms in bringing out a poorly functioning duplicated segment. Any abdominal mass may conceivably represent a tremendously dilated duplication, and an important diagnostic maneuver in such an instance entails urethroscopic and vaginal examination while gentle pressure is applied to the mass; egress of urine or pus from the dilated sac may thus pinpoint the ectopic opening and allow subsequent urographic delineation.

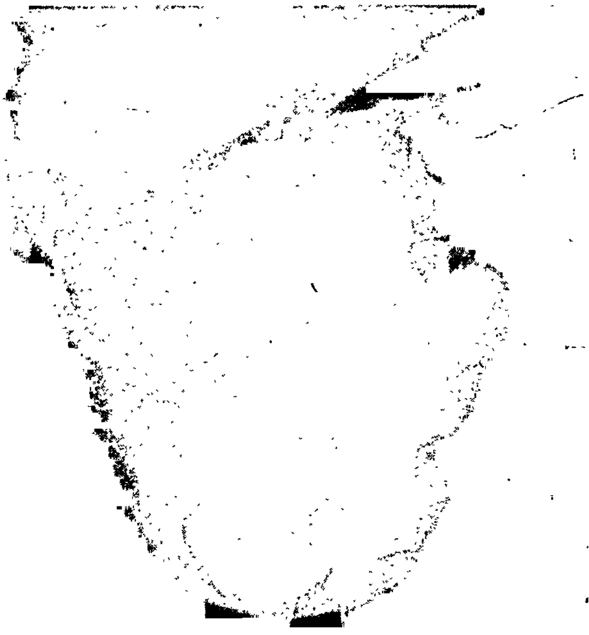

Fig. 8.—Catheter injection of hydronephrotic upper segment outlining only one loop of tortuous, dilated ureter.

Comment

The frequency with which nonvisualized duplicated segments are discovered will mirror the vigor with which they are sought and the thoroughness with which the investigation is carried out. A more general awareness of the incidence of ureteral duplication, the pathological abnormalities entailed, and the characteristic diagnostic features will undoubtedly increase the numbers discovered and afford a solution to otherwise obscure urinary tract findings.

That a ureteral duplication in one kidney should arouse suspicion as to the possibility of its occurrence in the contralateral kidney seems a feature worthy of inclusion in the list of diagnostic characteristics. Should urinary tract disease prescribe urologic study, the exclusion of duplication as etiological in such an instance would seemingly be indicated. Additionally, more general attention should be directed to the fact that an ectopic orifice outside sphincter control may not necessarily be productive of incontinence in the female.

1405 E. Ann St. (Dr. Thompson).

ADVANTAGES OF COLD CONIZATION

INTRODUCTION OF A NEW INSTRUMENT

Arthur R. Fleming, M.D., Gallipolis, Ohio

A new conization instrument makes use of an adjustable, disposable blade, the arc of which can be varied, depending on the amount of tissue to be removed; the arc is preset before the cut is started. The deepest portion of the cutting instrument is always directed toward the cervical canal. The advantages of cold conization are its diagnostic reliability, value in scientific study of the region, therapeutic efficiency, and probable high prophylactic value. Points against cold conization are fears of hemorrhage (immediate and late), cervical stenosis, and the possibility of interference with parturition. These factors become insignificant when one considers the consequences of one undiscovered malignancy. The therapeutic value of cold conization in restoring a diseased, symptomatic cervix to health is also of great importance.

It is the purpose of this paper to show that cold conization is, in general, the procedure of choice over all other forms of biopsy of the uterine cervix. The procedure would not be used in a patient with an obviously cancerous lesion, and some physicians would except the pregnant patient with a positive Papanicolaou smear. The adolescent patient who requires curettage may also be justifiably excepted.

Methods of Cervical Biopsy

Several authors have emphasized the superiority of the thick cone specimen over specimens obtained by other methods of cervical biopsy.[1] Practically all of these authors concerned themselves with the value of thick cold conization in the study, diagnosis, and/or treatment of carcinoma in situ of the cervix. Reagan and Hicks [1b] felt that punch or wedge biopsies may fail to include the focus of carcinoma in situ. They also noted a higher incidence of carcinoma in situ in those series in which a study was made of the entire cervix or the excised specimen. Scott and Reagan,[1c] in support of the thick cone biopsy, stated, "There is rarely a rational foundation for relying on incomplete or questionable diagnostic tests. When one accepts the premise that hospitalization is necessary to diagnose carcinoma in situ and early invasive cancer, instruments designed for use on ambulatory patients lose much of their appeal and value."

Four quadrant biopsy does not rule out invasive carcinoma.[2] The diagnostic failure rate with all forms of biopsy, including shallow cone specimens, varies from 16 to 22%.[3] Foote and Stewart [4] projected that if adequate four quadrant biopsies could be obtained the diagnostic failure rate could be reduced to 8%. However, the difficulties in consistently obtaining adequate four quadrant biopsies are numerable. The tissue obtained is frequently unreliable for any one or several of the following reasons: (1) absence of stroma, (2) absence of the squamocolumnar junction, (3) trauma, (4) orientation impossible, or (5) a limited sample.

Office biopsy in my practice has been replaced by the Papanicolaou smear, except in the case of a patient with an obviously cancerous lesion of the cervix. As an outpatient procedure, the Papanicolaou smear more consistently gives a general repre-

---

From the Department of Obstetrics and Gynecology, Holzer Hospital and Clinic.

sentation of the entire cervix than does office biopsy.[1a] The Papanicolaou smear, if used in this manner, must be considered with its generally accepted 5% chance for error.[5] Some gynecologists decide whether cold conization is necessary by the results of the Papanicolaou smear. If it is positive, cold conization is used. If it is negative, less accurate forms of biopsy are used. When anesthesia is required for dilatation and curettage, cold conization should be performed regardless of prior outpatient cellular or tissue studies. The negative Papanicolaou smear must not dictate inadequate and incomplete evaluation of the cervix.

Advantages of Cold Conization Over Other Types of Biopsy

	Cold Conization	Other Types of Biopsy
Diagnostic failure rate	<5%	22%
Prophylactic value	High	Little or none
Therapeutic value	High	None
Pathological value	High	Low
Specimen size	Adequate	Inadequate
Specimen fragmented	Infrequent	Frequent
Squamocolumnar junction	Completely represented	Incompletely represented
Endocervical canal	1 to 3 cm.	Not represented
Stroma	Adequate	Often inadequate
Orientation	Rarely impossible	Frequently impossible
Tissue trauma	Small	Great
Repeat tissue sampling required	Rarely	Frequently

Gusberg and Moore[6] and Foote and Stewart[4] have stressed the impossibility of regularly diagnosing carcinoma of the cervix by symptomatology or clinical appearance. The trigger site for carcinoma of the cervix is the squamocolumnar junction.[6] Most authors feel that carcinoma begins in or near this area and extends up the cervical canal. Therefore, to properly diagnose, study, and treat conditions in this region, the entire circumference of the squamocolumnar junction and at least 1 to 2 cm. of the endocervical canal must be represented in the biopsy. This is possible only with the thick conization specimen.

The present debate as to the significance of metaplasia and its relationship to carcinoma in situ of the cervix may in the final analysis show that cold conization is a prophylactic procedure. Carson and Gall[7] showed that metaplasia accompanied carcinoma of the cervix in 89% of their patients, this being another factor in favor of cold conization.

The therapeutic value of cold conization in restoring a diseased, symptomatic cervix to health is also of great importance. Most patients requiring dilatation and curettage are parous and, as such, frequently have some degree of chronic cervicitis. When punch biopsy is used on these patients, a poor representation of the entire cervix is obtained, and little is done for the cervicitis. If cold conization is used, the cervix is well represented pathologically and much, if not all, of the diseased portion of the cervix is removed.

The advantages of cold conization are (1) its diagnostic reliability, (2) its value in scientific study of this region, (3) its therapeutic efficiency, and (4) its probable high prophylactic value. It is difficult to show that any test or procedure is 100% accurate, but cold conization appears to give more accurate results than do other forms of cervical biopsy. The table outlines the foregoing statements and shows the advantages of cold conization over other forms of biopsy of the cervix.

Points against cold conization are fears of (1) hemorrhage, immediate and late, (2) cervical stenosis, and (3) possibility of interference with parturition. Certainly these factors become insignificant when one considers the consequences of one undiscovered malignancy.

Results of Cold Conization in Two-Hundred Sixty Patients

In an effort to evaluate these contraindications, a review of 260 patients who had undergone cold conization was instituted. In this study immediate hemorrhage unfortunately was not measured, but admittedly with the straight knife or even an angulated knife it can be troublesome. This bleeding may be due to undercutting the deep endocervical canal. This results from not being able to cut in a consistent plane to remove a true cone of tissue. Because of limited space and frequently poor descent of the cervix, one is not able to keep the tip of the knife blade pointing toward the endocervical canal. The operator may actually be cutting directly into a descending branch of the uterine artery. This could account for excessive bleeding, since the undercut portion is not excised with the specimen. The bleeding points are therefore not exposed to facilitate cauterization. This may also explain a poor end-result showing an endocervical ledge peeping through the healed cervical os, mimicking an endocervical polyp. This immediate hemorrhage, inconsistent tissue sampling, and an occasional poor end-result led me to develop the new conization instrument (fig. 1) described later.

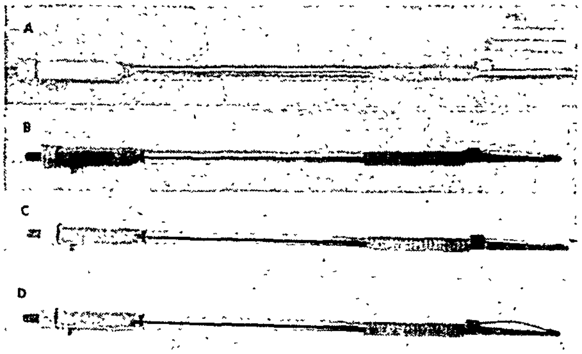

Fig. 1.—*A*, conization knife of new design, showing disposable blade. Turning knurled knob moves outside barrel forward and increases arc in blade. *B*, blade partially arced. *C*, blade at rest. *D*, blade arced for average cervix.

Late hemorrhage from the cervix was seen in only 9 (3.5%) of the 260 patients in this study. Of these nine, all returned within 10 days from the time of discharge. Bleeding occurred on the 4th postoperative day in one, on the 6th or 7th in six, and on the 10th in two. Six required rehospitalization. None of these patients required transfusion therapy; two required suturing and pack to control bleeding; three, cautery and pack; and four, pack only.

The danger of stenosis is real. It is our impression that it is particularly so in those patients requiring heavy cauterization and in postmenopausal patients. It is too early in this study to judge the exact incidence of stenosis. However, 5, or 11.1%, of the 45 patients in whom hysterectomy was required showed some degree of stenosis; fibrinous adhesions, which possibly contribute to stenosis, were noted in 10 (22.2%). Only 115 of the 215 patients not requiring hysterectomy have been followed for more than three months. In this group only four have shown stenosis as measured by a 9 F. sound. In judging the hysterectomy specimens for stenosis, no set rule or measure was used. Any specimen description mentioning an indication of postconization stenosis was counted as showing narrowing of the cervical canal. Most authors feel that adequate, periodic office dilatation rules out this complication.

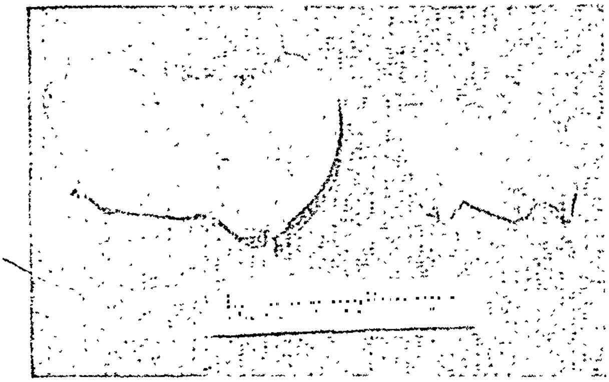

Fig. 2.—*Left*, specimen from cervix of multiparous woman. *Right*, specimen from cervix of a nulliparous woman. Both specimens represent entire circumference of squamocolumnar junction and at least 1.5 cm. of endocervical canal. Average thickness of specimens is from 6 to 8 mm.

A New Conization Instrument

The new conization instrument makes use of an adjustable, disposable blade, the arc of which can be varied, depending on the amount of tissue to be removed; the arc is preset before the cut is started. The deepest portion of the cutting instrument is always directed toward the cervical canal. This avoids undercutting and leaves all cut surfaces clearly exposed for cauterization and contact with coagulating substances (fig. 1).

Depending on the operator's desire, the cutting edge of the blade may be directed to the right or to the left. The amount of arc of the blade is preset by the gynecologist and depends on the amount of tissue to be removed. This is determined by the size of the cervix and staining qualities as outlined with 7% tincture of iodine. When necessary the cervix is dilated and conization is carried out with a sawing motion. The cut is started at 4 to 5 o'clock on the right or 7 to 8 o'clock on the left. This tends to keep the bleeding below the cutting edge and permits better visualization. Figure 2 shows two specimens obtained with use of the new knife. It is my opinion that this instrument has definitely decreased initial blood loss with cold conization and improved the end-result. Pathologically, specimens obtained with this instrument are the same as with a straight or angulated knife. The improvement is found in the diminished blood loss and the ease with which the specimen is obtained.

Prior to the use of this instrument, it was not unusual to use 10, or even 20, 4-by-4-in. sponges while performing a cold conization. Since institution of its use, it is unusual to use more than three such sponges, and frequently only one is required. To date over 60 conizations have been performed with this instrument, and only one patient has returned with late hemorrhage. This is not necessarily significant, due to such factors as improved technique, greater experience, and less initial hemorrhage, requiring less cauterization.

Comment

Several authors [1d] have mentioned that conization does not, as a general rule, interfere with pregnancy or labor. There have been only three patients in this series who have delivered after conization. None of these patients showed any difficulty with labor or delivery. There have been two abortions, in one of which cervical incompetence as a result of conization may have played a part. One cannot dismiss these complications lightly. One must weigh their consequences with not finding and/or not preventing a malignancy and with the therapeutic value of cold conization.

Reliable diagnosis and treatment demand not only adequate tissue but complete and thorough pathological examination. Close cooperation between gynecologist and pathologist will increase the incidence of positive findings and thereby benefit the patient. The pathologist prepares the conization specimen by cutting it at 2-mm. intervals about the entire circumference of the cervical os and serial blocks are examined.

In this study, 49 patients showed atypical cellular changes and/or malignancy of the cervix. Of these, 24 had a conization diagnosis of metaplasia or frank malignancy and underwent hysterectomy. Of the 14 patients who had a conization diagnosis of carcinoma in situ, 3 showed residual atypical tissue in the specimen taken at hysterectomy; of the 5 who had a diagnosis of metaplasia, none showed residual atypical findings; of the 5 who had a diagnosis of invasive carcinoma, 4 showed residual atypical findings.

This coincides with the findings of others.[1d] It also serves as a warning to those advocating thick conization as adequate treatment for carcinoma in situ. The youthful patient desiring to become pregnant after a conization diagnosis of carcinoma in situ is of course permitted to do so.

Dilatation and curettage offers an excellent opportunity to find and record as much as possible about the patient's pelvic anatomy. If we are thorough we must make every effort to (1) record an accurate pelvic examination, noting sizes in centimeters, (2) note station of descensus, (3) note support of the bladder and pelvic floor, and (4) avoid premature office cauterization prior to dilatation, curettage, and cold conization. In an effort to be even more complete, routine culdocentesis was used in 160 patients in this series. This was done to aid diagnosis and with the hope that an unsuspected malignancy might be found. The fluid obtained was sent to the laboratory for Papanicolaou smear from the sediment. To date one unsuspected Krukenberg tumor has been diagnosed in this manner.

The technique used at Holzer Hospital for dilatation, curettage, and cold conization incorporates the following principles: gentle cleansing of the vaginal canal with an antiseptic solution and catheterization followed by careful bimanual examination. The cervix is stained with 7% tincture of iodine which outlines the extent of the disease of the portio. Every effort is then made to excise this diseased area, and a margin of normal tissue is also taken. Dilatation of the cervix is performed only enough to permit use of the coning instrument. Cauterization is carried out with the lowest effective current possible. Curettage is next performed after the cervix is dilated for this purpose. The conization site is then packed with oxidized cellulose, which is left in place. Sutures to control bleeding are not used routinely. A vaginal pack is then inserted after culdocentesis, and the patient is returned to the recovery room. The pack is removed the next morning, and the patient is discharged.

Since the most likely time for hemorrhage, in this study, has been from the 7th to the 10th postoperative day, the patients are seen 7 to 10 days from discharge. On the first office visit the patient is advised to use a dilute vinegar douche twice weekly and nightly instillations of a sulfonamide cream. The majority of these patients show complete healing and absence of vaginal discharge by the third postoperative week.

If hysterectomy is anticipated the patient is placed on therapy with antibiotics. The operation is performed within 48 to 72 hours after conization, otherwise it is delayed six to eight weeks.

Summary

Cold conization is the most accurate form of cervical biopsy, its advantages being (1) its diagnostic reliability, (2) its scientific value in study of the cervix, (3) its therapeutic efficiency in treating chronic cervicitis, and (4) its probable high prophylactic value. Points against cold conization are the following possible complications: (1) hemorrhage, immediate and late, (2) cervical stenosis, and (3) possibility of interference with parturition. Cold conization is advised in any patient in whom dilatation and curettage is required, regardless of prior outpatient cellular or tissue reports. The therapeutic, prophylactic, and diagnostic value of cold conization is felt to outweigh the possible complications of the procedure. The consequence of one undiscovered malignancy also influences this opinion. A new instrument of my design, introduced for performing cold conization, diminishes immediate hemorrhage and contributes to a better end-result.

First Avenue and Cedar Street.

This study was supported in part by the Sisters of Mercy, Mercy Hospital, Baltimore, Md., and the Holzer Clinic.

The V. Mueller Instrument Company, Chicago, cooperated in the development of the instrument described in this paper. The Crescent Manufacturing Company, Freemont, Ohio, cooperated in development of the blades used in the instrument.

CLINICAL NOTES

PSYCHOSIS RESULTING FROM MYXEDEMA

REPORT OF A CASE

Fiore R. Rullo, M.D.
and
Frank N. Allan, M.D., Boston

In recent years, medicinal treatment of psychoses has attracted great interest on the part of the medical profession as well as the public. While attention has been focused on the use of new drugs which exert merely a palliative effect, it should not be forgotten that a specific remedy in pill form has been available for the treatment of one type of psychosis for over 70 years. The experience described in the following case report illustrates the importance of recognition and consistent treatment of this psychosis resulting from myxedema.

A 71-year-old woman was admitted to the hospital on a Saturday in late August, 1956. She had been an office patient at the Lahey Clinic on a number of occasions since 1951, when she came for help because of symptoms of diabetes mellitus. She had not been seen for nearly a year, and on this week-end her original physician and the records of her previous examinations and treatment were not available. According to the report of her family, she had shown progressive deterioration in both physical and mental health for many months. She had become so weak and unsteady when on her feet that she was bedridden much of the time. Urinary and fecal incontinence had made home care impossible. She was mentally disturbed and unable to answer questions. She resisted the efforts of the physician to make a physical examination and threatened to strike the examiner.

It was evident that the mental disorder was serious. The patient suffered from delusions and hallucinations; she was disoriented as to time and place and was sometimes unable to identify members of her family. She became agitated, noisy, and violent when disturbed by nurses or doctors. She resisted efforts to give her medication, an intravenous infusion, and blood tests. Restraints were employed to keep her in bed, but one night she was able to release the fastenings, wandered across the ward, and climbed into bed with another woman patient. It was first thought that she would have to be committed to a mental hospital; however, a thorough appraisal of the physical status led to deferment of such a decision.

The patient presented the facial appearance of myxedema. Her skin was dry and cold, her hair was thin, and her voice was harsh and low-pitched. When her previous clinic record was secured, further information became available. She had shown signs of thyroid deficiency in July, 1953, and had been advised to take desiccated thyroid. When last seen in September, 1955, she had been instructed to continue the thyroid treatment regularly. It was now learned, however, that she had failed to take the thyroid tablets as prescribed and for many months had taken none at all.

Treatment with desiccated thyroid was begun. Five days later the patient began to show some signs of improvement, and from then on a gradual change for the better occurred. She became cooperative and more alert mentally. By the time of her discharge from the hospital two weeks later, she was still slightly disoriented at times, but the improvement in her mental state was considered remarkable by both the hospital personnel and the family. Later on, we received reports that she was enjoying good health and continuing the thyroid treatment.

In January, 1958, this favorable result was confirmed on a visit to the patient's home. She was keeping house successfully for her husband and son in a four-room apartment. The family said that her memory and mental acuity were normal. She was alert and quick in actions and response. She presented the appearance of good health too, but it was thought that she still had a minimal degree of thyroid deficiency. She was advised to increase the dosage of thyroid to 1½ grains (0.1 Gm.) a day.

Comment

The occurrence of mental symptoms resulting from myxedema was first described in the report of a committee nominated on Dec. 14, 1883, by the Clinical Society of London to investigate the subject of myxedema.[1] The chairman of this committee was Dr. William Ord who, in 1877, reported on a number of cases and proposed the term "myxoedema" for the condition first described clearly four years earlier by Sir William Gull. The committee collected information from many sources and compiled a volume of more than 200 pages. Among the cases of myxedema which they described, major psychotic symptoms were reported in 15%.

Since then, a number of other reports of psychosis occurring with myxedema have appeared, but most of them have dealt with only one or two patients. Possibly the frequent occurrence of psychosis in the cases reported by the committee was the result of the fact that only patients with severe, untreated myxedema were given diagnoses at that time. An important exception is a paper published by Asher[2] in 1949. He described 14 patients who had myxedema with psychosis; 10 of these patients had been admitted to mental hospitals. Asher gave credit to a novel written by a physician for his own acquaintance with the problem. In "The Citadel," A. J. Cronin,[3] who had practiced medicine before he became a successful writer, described a dramatic scene in which young Dr. Manson was asked by

---

From the Department of Internal Medicine, Lahey Clinic.

an older doctor to help certify "a dangerous lunatic" for commitment to a mental hospital. The latter thought that his certification would be confirmed as a mere formality. "It's a bad business," he said, "but it won't take you long." However, Dr. Manson was alert to recognize the physical features of thyroid deficiency and pleaded for a trial of thyroid treatment. Complete recovery followed. Of Asher's 14 patients, dramatic and complete recovery occurred in 9, limited improvement in 2, and no change in one. Two patients died shortly after treatment was begun.

Summary

This case report describes a psychosis developing as a result of neglected myxedema. The patient might have been committed to a mental hospital with a diagnosis of senile dementia if the need for thyroid treatment had not been recognized. The manifestations of the psychosis disappeared within a few weeks after treatment of the thyroid deficiency with desiccated thyroid, illustrating the recovery that can be expected in most of these patients after employment of adequate and continuous treatment.

ASTEROID HYALITIS

INCIDENCE OF DIABETES MELLITUS AND HYPERCHOLESTEREMIA

J. Lawton Smith, M.D., Baltimore

Asteroid hyalitis (Benson's disease) presents a characteristic and impressive ophthalmoscopic picture generally regarded as of little clinical significance. Recently a patient with bilateral asteroid hyalitis was found to have a markedly elevated serum cholesterol level. This prompted a study of additional patients. The incidence of diabetes mellitus and hypercholesteremia found in these patients is of interest.

Duke-Elder's[1] discussion of asteroid hyalitis is excellent and may be profitably summarized here. He notes that crystalline deposits in the vitreous are relatively uncommon. Dor[2] found them 32 times in 82,732 patients and Westphal[3] 40 times in 65,000. However, these brilliant bodies were known even in preophthalmoscopic days. They were all referred to as "synchysis scintillans" until Benson[4] differentiated the white spherical bodies as "asteroid hyalitis" because they had the appearance of "hundreds and thousands of small spheres of a light cream color . . . like the stars in a clear night." Rutherford[5] reported 18 cases in seven years and found records of 56 cases in the literature. The age of affected patients averaged 60 years and varied from 30 to 84. Asteroid hyalitis was said to be commonest in the seventh and eighth decades, three times as frequent in males as in females, and usually unilateral, with only about 25% of cases affecting both eyes.

Duke-Elder further states that these bodies resemble snowballs, varying in color from a shiny white to a dull cream, and in number from a very few to innumerable. The vitreous may show some degenerative changes, but it retains its solidity so that these mobile bodies return to their original location and do not settle to the bottom of the vitreous chamber.

Those who reported chemical and histological examinations[6] of these bodies have considered them as calcium soaps (palmitate, stearate, and margarate), with sodium and calcium phosphates and chlorides and various fatty or lipoid substances. Tests for cholesterol have been said to be negative, but these have primarily consisted of treating the particles with a drop of sulfuric acid and finding no play of colors, rather than definite chemical analyses. The cause is unknown, and although associated disease has been noted from time to time (arteriosclerosis, nephritis, diabetes,[7] choroiditis, retinal hemorrhages, thrombosis),[1] this has been considered coincidental.

From the Wilmer Ophthalmological Institute, Johns Hopkins University and Hospital.

Differential diagnosis concerns synchysis scintillans, which is rarer, more often bilateral, and seen frequently in younger persons (under 35 years). These are flat, angular crystals which occur in a fluid vitreous and often lie hidden below only to flash up and quickly settle on motion of the eye. Duke-Elder describes them as "presenting a beautiful and quite characteristic picture as they flash by with a gleam of burnished gold." These are considered to be cholesterol crystals, although needles of tyrosine and margarine have been reported. In summary, asteroid hyalitis is said to be more common, occurring in a substantially normal vitreous, and to consist of calcium soaps. Synchysis scintillans occurs in a fluid vitreous and is probably made up of cholesterol crystals. Neither produces symptoms or loss of vision nor has been modified by treatment.

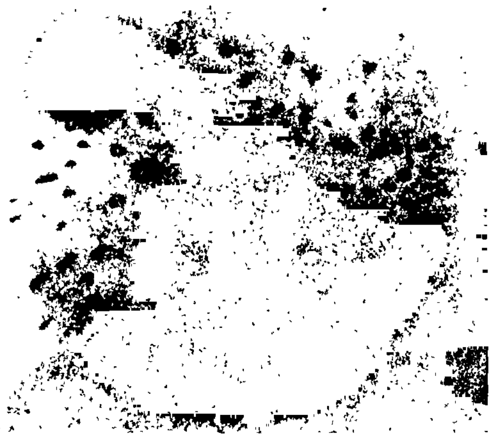

Fig. 1.—Fundus of eye, showing asteroid hyalitis (focused in vitreous).

Clinical Data

A patient (see table, case 8) with bilateral asteroid hyalitis presenting with senile cataracts was found to have a serum cholesterol level of 620 mg.% and far-advanced myxedema. Bilateral cataract extractions and thyroid therapy produced a dramatic clinical response in this patient, although no unequivocal change was noted in the vitreous opacities. In the ensuing 18 months, 18 additional patients with asteroid hyalitis have been seen (fig. 1 and 2). Analyses of blood chemistry were obtained from 16 of these patients, and the data are summarized in the table.

Comment

Of the 19 patients with asteroid hyalitis seen, 10 have been males and 9 females. The age range has been 51-83 years, with an average of 64 years. Seventeen cases were unilateral and two bilateral. Diabetes mellitus was definitely present clinically in six patients. Five other patients had blood sugar levels of over 110 mg.%, although no definite clinical diagnosis of diabetes mellitus had been made. Vascular disease was evident, with histories of one basilar artery thrombosis and four myocardial infarctions in the group. The diastolic pressure was 90 mm. Hg or over in 7 of 10 patients with recorded blood pressures. The nonprotein nitrogen level was between 35 and 60 mg.% in 10 patients. A history of cholelithiasis was noted in three patients. Macular disease was prominent, with senile macular degeneration, disciform degeneration, diabetic retinopathy, circinate retinopathy, and giant drüsen seen in a total of seven cases. Glaucoma was encountered in six patients.

The serum cholesterol levels were of particular interest. They were as follows: 100-200 mg.% (one patient, who had diabetes), 200-300 (four), 300-400 (nine), and over 400 mg.% (two).

Thomas[8] has performed several large series of control determinations of serum cholesterol level in the clinical chemistry laboratory of the Johns Hopkins Hospital and considers 150-250 mg.% as normal for this laboratory. Over 300 mg.% is considered definitely elevated. Serum cholesterol levels exceeded 300 mg.% in 11 of the 16 patients, and the average for the 16 patients was 326 mg.%. It is of interest that the second patient with bilateral asteroid hyalitis had a grossly yellow, hyperlipemic serum. The serum cholesterol level was 375 mg.% and the total serum lipids 1,040 mg.% in this instance.

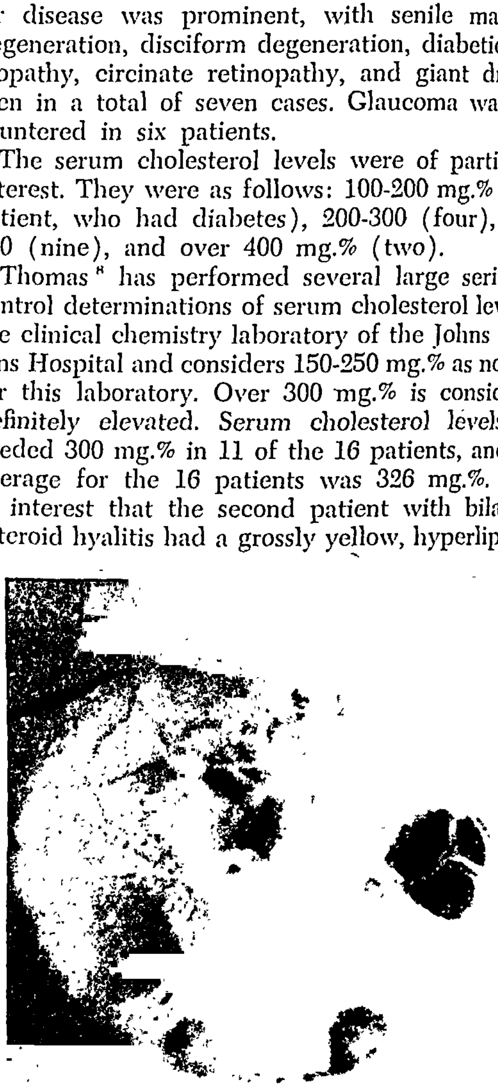

Fig. 2.—Same eye as figure 1, showing glaucomatous atrophy of optic nerve and circinate retinopathy (focused on retina).

Lens Cholesterol Level.—A cataractous lens was removed from the eye of a patient with asteroid hyalitis, and this lens weighed 187 mg. Ether extraction and subsequent analysis revealed 0.71 mg.

of cholesterol in this lens. A control senile cataract weighing 185 mg. revealed 0.63 mg. of cholesterol. This difference was not thought to be of note.

The necessity for caution in interpreting serum cholesterol levels has recently been stressed. Variability in determinations between different laboratories and fluctuations in the same individual must be considered. However, as those causes for hypercholesteremia so far found (diabetes mellitus, myxedema, hepatobiliary disease) are treatable diseases, it is suggested that patients with asteroid hyalitis have a determination of serum cholesterol level and blood sugar level.

* Normal = 4-8.

The blood-vitreous barrier may explain a delay in appearance of these particles in the avascular vitreous, and hence the age of the patients. Altered permeability of ocular vessels (as in diabetes and arteriosclerosis) may be a source for a chemical leak into the vitreous. However, many questions about this entity remain unanswered. The pathogenesis of asteroid hyalitis and its frequent unilaterality await further chemical studies of the vitreous.

Summary

The average serum cholesterol level in 16 patients with asteroid hyalitis was found to be 326 mg.%. Definite diabetes mellitus was found in six of these patients, and borderline carbohydrate tolerance was noted in five others. It is suggested that patients with asteroid hyalitis have determinations of serum cholesterol and blood sugar levels until a sufficiently large number of cases can be collected for definite statistical value.

102 Gerry Rd., Chestnut Hill 67, Mass.

Dr. Frederic M. Reese supplied the information for case 2 in the table.

CHEMOTHERAPY OF CHORIOCARCINOMA AND RELATED TROPHOBLASTIC TUMORS IN WOMEN

IN THIS issue on page 845 is a stimulating report from the Endocrinology Branch of the National Cancer Institute which establishes the usefulness of the folic acid an agonist, Methotrexate, in the treatment of women with choriocarcinoma and related trophoblastic tumors. These investigators have treated 27 women with advanced metastatic trophoblastic disease with high doses of Methotrexate applied intermittently in five-day courses. Twenty-three of these very ill patients survived long enough to receive more than one course of therapy. All but one of these showed a distinct therapeutic response as reflected in a marked drop in urinary gonadotropin titer. This was accompanied by (*a*) striking regression of pulmonary metastases, (*b*) reduction in palpable and visible pelvic disease, (*c*) subsidence of objective neurological manifestations of cerebral metastases, and (*d*) general clinical rehabilitation of the patient. Five of these women continued to show no evidence of residual disease for 8 to 29 months after treatment. Unfortunately, the remainder have shown hormonal or clinical evidence of persistent disease or have subsequently developed Methotrexate resistant disease which has proved lethal despite continued therapy with Methotrexate or other carcinolytic agents.

The striking consistency of the immediate response of these patients to Methotrexate clearly establishes the remarkable initial effectiveness of this form of therapy. Nevertheless, the authors advisedly emphasize that the variability in the clinical course of women with trophoblastic tumors makes it very difficult to offer a final evaluation of the effect of Methotrexate therapy on the over-all outcome of the disease in this limited group of patients.

Through the coöperation of physicians encountering these rare cases it may be hoped that these studies may be extended and further elaborated. In all events, this report represents a unique model for quantitative assessment of therapeutic response of a malignant tumor to a specific agent. The hormone-producing tumors provide an unusual opportunity for such observations, and these investigators have offered an excellent example of the type of quantitative information so clearly needed in the evaluation of cancer chemotherapy. The practical as well as theoretical value of these studies warrants our most cordial interest and further cooperation.

NEW HORIZONS FOR THE TUBERCULIN TEST

Although the tuberculin test has always had an important place in the diagnosis and control of tuberculosis, recent developments indicate that the test will be even more useful in the decades just ahead. The tuberculosis mortality rate has shown a remarkable drop in the past 10 years, followed by a slower decline in the tuberculosis case rate. An even more significant change in the United States is the diminishing risk of acquiring new infections. In certain areas of the nation, particularly in the Northwest, entire school populations are tuberculin negative. Results of tuberculin testing in Navy recruits provide a broad view for the United States as a whole. In 1950, 9% of white recruits were classified as tuberculin reactors. Only seven years later, the proportion of reactors had decreased by one-third. The implication of such findings, substantiated by tuberculin testing programs in various parts of the country, is that new infections with virulent tubercle bacilli must be approaching the low figure of one per 1,000 persons per year.

The complacent attitude, once widely held, that tuberculous infection is an inevitable consequence of attaining adult life is now outmoded, as is the concept that positive reactors are immune and are not likely in the future to develop tuberculous disease. Indeed, current findings demonstrate that most new cases of tuberculosis occur in persons who were infected many years ago. This situation points up the significance of a positive reaction to tuberculin as an indicator of substantial disease risk, and emphasizes the necessity to *identify* the tuberculin reactors in the population, thus delineating the areas and groups where tuberculosis control efforts can be most effectively applied.

The dramatic change in the tuberculosis infection rate and the constantly diminishing proportion of positive reactors in the population have important implications for medical and public health practice.

In differential diagnosis, the pediatrician is no longer the only advocate of tuberculin testing. Now that many adults are negative reactors, the tuberculin test should be a routine part of every examination when pulmonary pathology is suspected.

The method of choice in administering the tuberculin test is the intracutaneous (Mantoux) test. Indeed, it has been well established in numerous trials that a Mantoux test with a dose of tuberculin equivalent to 0.0001 mg. of the international standard purified protein derivative (PPD-S) will produce a reaction in practically all cases of proved tuberculosis with a minimum of false negatives. It is customary in interpreting the test to regard reactions of 6 mm. or more of induration as positive. There is now some evidence, however, that a better dividing point might be 8 or 10 mm., since almost all persons with tuberculosis have reactions this size or larger, and smaller reactions may be nonspecific.

Properly administered and interpreted, the tuberculin test can promptly rule out the tubercle bacillus as the etiological agent in many instances and allow a more diligent and fruitful search for tuberculosis in positive reactors. Wider use of this readily available and inexpensive test should result in considerable saving of time and money to both patient and physician. The need for the patient to return for a reading of his test may well be a blessing in disguise. All too often, patients with serious pulmonary pathology have only the symptoms and signs of a superimposed acute infection. Obtaining temporary relief, they see no need for a return visit until progression of the underlying disease has become manifest. A test to be read three days later might improve the follow-up of chest diseases seen in office practice.

The continued decline in the proportion of reactors in the population will also increase the usefulness of tuberculin testing for tuberculosis case finding in various community groups. Numerous studies have shown that tuberculosis is heavily concentrated among reactors to tuberculin, particularly among those with the strongest reactions. In many population groups, it is already feasible to offer chest x-rays and other diagnostic procedures only to the small group of positive reactors.

With therapeutic agents which can reverse the infectiousness of nearly all cases, with adequate facilities for isolation, and with the help of the tuberculin test to concentrate diagnostic, case finding, and therapeutic efforts where they will be most effective, the odds against the tubercle bacillus now are greater than ever before. In most areas of the United States today, it should be possible to set our sights not merely for the control of tuberculosis but toward its eradication. As this goal is approached, the identification of the small minority of the population among whom infection still persists will become increasingly important. The tuberculin test can already perform this function with considerable precision, and recent studies indicate that even better testing products and techniques will shortly become available.

IATROGENIC DISEASES IN CHILDREN

It has often been said that there is no gain without a relative loss. This is as true in medicine as in other fields. The fact that the physician in treating his patient can unwittingly cause disease which may be worse than the one being treated is unfortunate, but the only thing that is worse than making a mistake is not to correct it. In the case of retrolental fibroplasia,[1] now mercifully rare, a great deal of damage was done before the cause was recognized. Premature babies who needed oxygen were treated more generously than was needed, but *once this fallacy was recognized an end was written* to the chapter. Kernicterus presented a similar situation. It often developed in premature infants unassociated with any blood incompatibility on the 6th or 7th day of life rather than on the 2nd or 3rd day as in full-term infants. It has been shown that these premature infants had been given vitamin K, or in a few cases sulfisoxazole, in too large doses.

In treating infants overdosage must be constantly guarded against. Clark's, Cowling's, Fried's, and Young's rules for arriving at a safe fraction of the adult dose for a child may serve as a convenient guide, but none are as safe as prescribing on the basis of milligrams per kilogram of body weight. Hypervitaminosis from an overdosage of vitamins A and D as well as K may occur. Some infants have less than average tolerance for vitamin D and on average or slightly greater than average doses may show symptoms of hypercalcemia. Hypercalcemia may also be caused by giving milk of magnesia daily for a long time. Fortunately these conditions are readily reversible. The sulfonamides may cause crystalluria, hematuria, and even anuria. Antibiotics by suppressing one group of organisms may leave a clear field for others which in some cases may be harder to control than the organisms originally being combated. This is particularly unfortunate in cases where these drugs were used prophylactically or without definite and valid indications.

In treating any infant the prolonged use of any drug should be avoided if possible. Great care should be exercised in determining the required dosage, and overdosage should be avoided at all times. Before any drug is given it is essential to know what undesirable side-effects may be expected and to make frequent checks so that these may be recognized early. Parents should be instructed to report evidences of hypersensitivity and other complications of treatment promptly so that the treatment may be modified in time to prevent undue suffering.

ORGANIZATION SECTION

REPORT OF THE SECTIONS OF THE SCIENTIFIC ASSEMBLY

SAN FRANCISCO MEETING, JUNE 23-27, 1958

SECTION ON ANESTHESIOLOGY

The Section on Anesthesiology held its first meeting jointly with the Section on Surgery, General and Abdominal, on Wednesday morning, June 25, in Veterans War Memorial Auditorium, with meetings on Wednesday and Thursday afternoons, June 25 and 26, in Masonic Temple. Fourteen papers were presented in addition to a symposium and panel discussion on "Spinal Anesthesia" with six papers.

At the business meeting on Wednesday, June 25, the Section Delegate, Dr. Edward B. Tuohy, reported on activities of the House of Delegates. The participants in the Scientific Exhibit from the Section on Anesthesiology were also introduced.

At the business meeting on Thursday, June 26, the following officers were elected: Chairman, Dr. John Adriani, New Orleans; Vice-Chairman, Dr. Edward T. Lawless, Upper Montclair, N. J.; Secretary, Dr. Vincent J. Collins, New York; Assistant Secretary, Dr. Kenneth K. Keown, Columbia, Mo.; Delegate, Dr. Joseph H. Failing, Los Angeles; Alternate Delegate, Dr. Ralph S. Sappenfield, Miami, Fla.; and Representative to Scientific Exhibit, Dr. Edwin L. Rushia, Augusta, Ga.

The Section sponsored eight exhibits in the Scientific Exhibit of which one received a certificate of merit and one honorable mention. In addition, the Section participated in the demonstrations on perinatal problems.

SECTION ON DERMATOLOGY

The Section on Dermatology met in California Masonic Memorial Temple on Tuesday, Wednesday and Thursday afternoons, June 24, 25, and 26. Thirteen papers were presented as listed in the program, together with a panel discussion on "Pruritus Ani et Vulvae and Other Dermatoses of the Anogenital Area."

At the business meeting on Tuesday, June 24, reports were presented from the Editor of *A. M. A. Archives of Dermatology* which was read by the Secretary; from Dr. Stanley E. Huff, Section Representative to the Scientific Exhibit; from the American Board of Dermatology which was read by Dr. Walter Lobitz, Assistant Secretary of the Board; from Dr. Winfred A. Showman, Section Delegate; from Dr. Donald Birmingham, Chairman, Industrial Dermatoses Committee; and from the Nominating Committee which was read by Dr. J. Walter Wilson.

Dr. Earle D. Osborne, Secretary General of the International Congress of Dermatology, discussed plans for the Congress in Washington in 1962.

At the business meeting on Wednesday, June 25, the following officers were elected: Chairman, Dr. Clarence S. Livingood, Detroit; Vice-Chairman, Dr. Rudolph H. Ruedemann, Albany, N. Y.; Secretary, Dr. Edward P. Cawley, Charlottesville, Va.; Assistant Secretary, Dr. Harry L. Arnold Jr., Honolulu, Hawaii; Delegate, Dr. Winfred A. Showman, Tulsa, Okla.; Alternate Delegate, Dr. Maurice J. Costello, New York; and Representative to Scientific Exhibit, Dr. Stanley E. Huff, Evanston, Ill.

The second paper which was scheduled on Wednesday's program was the Distinguished Lecture in Dermatology to be delivered by Dr. Francis E. Senear. Since Dr. Senear died early in the year, the Chairman asked for a period of silence at this time in the program in memory of the Section's distinguished friend and colleague.

The Section sponsored six exhibits in the Scientific Exhibit. There were two awards consisting of a certificate of merit and an honorable mention.

SECTION ON DISEASES OF THE CHEST

The Section on Diseases of the Chest held its first meeting on Wednesday morning, June 25, in California Masonic Temple. On Thursday morning, June 26, it met jointly with the Section on Radiology, and on Friday morning, June 27, it met jointly with the Section on General Practice in the Civic Auditorium in Polk Hall.

At the business meeting on Wednesday morning, June 25, the following officers were elected: Chairman, Dr. M. Jay Flipse, Miami, Fla.; Vice-Chairman, Dr. Seymour M. Farber, San Francisco; Secretary, Dr. Burgess L. Gordon, Albuquerque, N. Mex.; Delegate, Dr. J. Winthrop Peabody Sr., Washington, D. C.; Alternate Delegate, Dr. John P. Medelman, St. Paul; and Representative to Scientific Exhibit, Dr. Edwin R. Levine, Chicago.

The Section sponsored 12 exhibits in the Scientific Exhibit. There were four awards consisting of the Billings Gold Medal, a certificate of merit, and two honorable mentions. In addition the Section sponsored the Special Exhibit on Pulmonary Function under the chairmanship of Dr. George R. Meneely, Nashville, Tenn.

SECTION ON EXPERIMENTAL MEDICINE AND THERAPEUTICS

The Section on Experimental Medicine and Therapeutics met in the High School of Commerce on Wednesday and Thursday mornings, June 25 and 26, and jointly with the Section on Internal Medicine on Thursday afternoon.

At the business meeting on Thursday morning, June 26, the following officers were elected: Chairman, Dr. Charles H. Burnett, Chapel Hill, N. C.; Vice-Chairman, Dr. Jack D. Myers, Pittsburgh; Secretary, Dr. Elliot V. Newman, Nashville, Tenn.; Delegate, Dr. Edgar V. Allen, Rochester, Minn.; and Representative to Scientific Exhibit, Dr. Joseph F. Ross, Los Angeles.

The Section sponsored 22 exhibits in the Scientific Exhibit. There were four awards consisting of the Hektoen Gold Medal, a certificate of merit, and two honorable mentions.

SECTION ON GASTROENTEROLOGY AND PROCTOLOGY

The Section on Gastroenterology and Proctology met Tuesday, Wednesday, and Thursday afternoons, June 24, 25, and 26, in the Veterans War Memorial Auditorium.

At the business meeting on Wednesday afternoon, June 25, the following officers were elected: Chairman, Dr. A. W. Martin Marino, Brooklyn, N. Y.; Vice-Chairman, Dr. Joseph Kirsner, Chicago; Secretary, Dr. Wm. H. Dearing, Rochester, Minn.; Secretary-Elect, Dr. George Gordon McHardy, New Orleans; Delegate, Dr. Stuart T. Ross, Garden City, N. Y.; Alternate Delegate, Dr. Neil Swinton, Boston; and Representatives to Scientific Exhibit, Dr. Willard H. Bernhoft, Buffalo; and Dr. George Gordon McHardy, New Orleans.

The Section sponsored 22 exhibits in the Scientific Exhibit. There were three awards consisting of a certificate of merit and an honorable mention and, in addition, one exhibit contained material for which a certificate of merit was given for outstanding medical photography.

SECTION ON GENERAL PRACTICE

The Section on General Practice met on Wednesday, Thursday, and Friday mornings, June 25, 26, and 27, in Polk Hall, Civic Auditorium, the last meeting being held jointly with the Section on Diseases of the Chest.

At the business meeting on Wednesday morning, June 25, Dr. Lowry H. McDaniel, Tyronza, Ark., was named to organize an Association of Past Officers of the Section to aid the Executive Committee in an advisory capacity as well as to stimulate interest in the work of the Section. A report was rendered by Dr. Lester D. Bibler, the Section Delegate. The following resolution was adopted:

Whereas, The future of the family physician is important both to organized medicine and the American people, and

Whereas, Family practice in recent years has attained the status of a specialty, and

Whereas, Considerable confusion exists as to which group in the profession shall fulfill the function of the family physician of the future, and

Whereas, There is no existing standardizing or certifying agency to encourage and foster the preparation of physicians in the field of general medicine, and

Whereas, It is evident that without the goal of Board Certification in view all too few young physicians are availing themselves of general practice residencies, and

Whereas, Medical school administrators and educators have expressed the need for such standardization and certification in selecting faculties, and

Whereas, The House of Delegates of the American Academy of General Practice has adopted a resolution recommending study and cooperation with the Section on General Practice of the AMA directed toward the formation of a Board of General Practice, and

Whereas, These facts have led the Executive Committee of the Section on General Practice to the firm conclusion that the establishment of a Board of General Practice for the examination and certification of family physicians in general medicine and surgery as a special field of practice should be created as promptly as possible, and that proper study be directed toward this; therefore, be it

Resolved, That the Section on General Practice of the American Medical Association in cooperation with the American Academy of General Practice should proceed. with all de[illegible] speed toward the creation of a Board of General Prac[illegible] subject to its approval by the Advisory Board of Medical Specialties and the Council on Medical Education and Hospitals of the AMA; and be it further

Resolved, That such a certifying board should retain the principle of re-evaluation of diplomates at stated intervals consistent with the requirements of the AAGP for continuation study for maintenance of membership.

At the business meeting on Thursday morning, June 26, the following officers were elected: Chairman, Dr. S. A. Garlan, New York; Vice-Chairman, Dr. Thomas Goldsmith, Greenville, S. C.; Secretary, Dr. Eugene I. Baumgartner, Oakland, Md.; Delegate, Dr. Lester D. Bibler, Indianapolis; Alternate Delegate, Dr. Milton Casebolt, Kansas City, Mo.; and Representative to Scientific Exhibit, Dr. I. Phillips Frohman, Washington, D. C.

Credit in category I was given by the American Academy of General Practice to its members who attended the meeting.

The Section sponsored 20 exhibits in the Scientific Exhibit, 3 of which received awards consisting of a certificate of merit and two honorable mentions. The Section also sponsored the demonstrations on physical examinations for physicians "A P. E. for every M.D.," under the chairmanship of Dr. Charles E. McArthur, Olympia, Wash.

SECTION ON INTERNAL MEDICINE

The Section on Internal Medicine met in the High School of Commerce on Tuesday, Wednesday, and Thursday afternoons, June 24, 25, and 26, the last meeting being held jointly with the Section on Experimental Medicine and Therapeutics.

At the business meeting on Wednesday, June 25, attention was called to the coming Centennial of the Section in 1959, with discussion of the program.

The following officers were elected: Chairman, Dr. William B. Bean, Iowa City; Vice-Chairman, Dr. Henry D. Brainerd, San Francisco; Secretary, Dr. R. H. Kampmeier, Nashville, Tenn.; Delegate, Dr. Charles T. Stone Sr., Galveston, Texas; Alternate Delegate, Dr. Carter Smith, Atlanta, Ga.; and Representative to Scientific Exhibit, Dr. Henry T. Ricketts, Chicago.

There were no vacancies on the Board of Trustees for the Billings Fund. Dr. Francis Wood, Philadelphia, was chosen Billings Lecturer for 1959.

The Section sponsored 24 exhibits in the Scientific Exhibit. There were four awards consisting of the Billings Bronze Medal, a certificate of merit, and two honorable mentions.

SECTION ON LARYNGOLOGY, OTOLOGY, AND RHINOLOGY

The Section met in Masonic Temple, Wednesday, Thursday, and Friday mornings, June 25, 26, and 27, and all papers on the program were read and discussed as scheduled.

The recent death of Dr. Hugh Kuhn, Secretary of the Section since June, 1953, was noted with the proper observances.

At the business meeting on Friday, June 27, the following officers were elected: Chairman, Dr. Victor R. Alfaro, Washington, D. C.; Vice-Chairman, Dr. Harold F. Schuknecht, Detroit; Secretary, Dr. Walter E. Heck, San Francisco; Delegate, Dr. Gordon F. Harkness, Davenport, Iowa; Alternate Delegate, Dr. Dean M. Lierle, Iowa City; and Representative to Scientific Exhibit, Dr. Walter H. Maloney, Cleveland.

The Section sponsored 13 exhibits in the Scientific Exhibit. There were three awards, consisting of a certificate of merit and two honorable mentions.

SECTION ON MILITARY MEDICINE

The Section on Military Medicine met in Civic Auditorium on Wednesday, Thursday, and Friday mornings, June 25, 26, and 27.

At the business meeting on Thursday, June 26, the following officers were elected: Chairman, Dr. Alphonse McMahon, St. Louis, Mo.; Vice-Chairman, Dr. George H. Houck, Palo Alto, Calif.; Secretary, Dr. Charles H. Bramlitt, Washington, D. C.; Delegate, Dr. Charles L. Leedham, Cleveland; Alternate Delegate, Dr. Charles P. Campbell, Hackensack, N. J.; and Representative to Scientific Exhibit, Dr. Robert V. Schultz, Washington, D. C.

Dr. Paul W. Schafer, Washington, D. C., was appointed as consultant for audiovisual matters to aid the Secretary in developing the 1959 program.

Point credit was given to active and reserve officers of the Air Force, Army, and Navy who attended the Section meetings.

The Section sponsored 13 exhibits in the Scientific Exhibit. There were three awards presented, consisting of a certificate of merit and two honorable mentions. In addition, the Section cooperated in the group of exhibits on the history of medicine.

SECTION ON MISCELLANEOUS TOPICS

Session on Medical Professional Liability.—The session was held in Masonic Temple on Tuesday afternoon, June 24, under the chairmanship of Dr. Joseph F. Sadusk, Oakland, Calif. Four papers were presented as listed in the program.

Session on Traffic Accidents.—The session met in Masonic Temple on Wednesday afternoon, June 25. Dr. Fletcher D. Woodward was chairman. Six papers were presented, followed by a panel discussion on the prevention of motor vehicle accidents.

Session on Injury in Sports.—The session was held in Mark Hopkins Hotel on Thursday morning, June 26, with Dr. Allan J. Ryan, Meriden, Conn., as chairman. The program consisted of a symposium of seven papers.

Session on Allergy.—The session met on Friday morning, June 27, in Civic Auditorium. Dr. Orval A. Withers, Kansas City, Mo., and Dr. William B. Sherman, New York, co-chairman, presided over the session. Eight papers were presented as listed on the program, followed by a panel on asthma.

There were 12 exhibits in the Scientific Exhibit on various subjects from the Section on Miscellaneous Topics, one of which received a certificate of merit and one an honorable mention.

SECTION ON NERVOUS AND MENTAL DISEASES

The Section on Nervous and Mental Diseases met in Masonic Temple on Wednesday, Thursday, and Friday mornings, June 25, 26, and 27. Eighteen papers were presented as listed in the program.

At the business meeting on Thursday, June 26, the following officers were elected: Chairman, Dr. Kenneth E. Appel, Philadelphia; Vice-Chairman, Dr. E. S. Gurdjian, Detroit; Secretary, Dr. A. L. Sahs, Iowa City; Delegate, Dr. F. M. Forster, Washington, D. C.; Alternate Delegate, Dr. Karl O. Von Hagen, Los Angeles; Representative to Scientific Exhibit, Dr. Benjamin Boshes, Chicago; and Representative to American Board of Psychiatry and Neurology, Dr. A. B. Baker, Minneapolis.

The Section sponsored 14 exhibits in the Scientific Exhibit, of which one received a certificate of merit and two honorable mentions.

SECTION ON OBSTETRICS AND GYNECOLOGY

The Section on Obstetrics and Gynecology met in Civic Auditorium on Tuesday, Wednesday, and Thursday afternoons, June 24, 25, and 26. The first session was held jointly with the Section on Radiology. Fourteen individual papers were presented as well as a Symposium on Radiation Hazards with three papers.

At the business meeting on Thursday, June 26, the following resolution was passed:

WHEREAS, The American Medical Association is one of the component members of the Joint Commission on Accreditation of Hospitals, and

WHEREAS, The Section on Obstetrics in one of the largest and oldest component sections of the American Medical Association, and

WHEREAS, Obstetrics and Gynecology is a major specialty in the practice of medicine, and occupies a major role in medical activities carried out in hospitals, and

WHEREAS, Obstetricians and gynecologists are vitally concerned with all aspects of hospital standards in regard to services, accreditations, and training; therefore, be it

Resolved, That the Section on Obstetrics and Gynecology petitions the Board of Trustees of the American Medical Association for representation on the Joint Commission on Accreditation of Hospitals through the American Medical Association membership on said Commission.

Plans were instituted for the Centennial celebration of the Section in 1959, and officers were elected as follows: Chairman, Dr. Nicholson J. Eastman, Baltimore; Vice-Chairman, Dr. Curtis J. Lund, Rochester, N. Y.; Secretary, Dr. Keith P. Russell, Los Angeles; Delegate, Dr. Ralph E. Campbell, Madison, Wis.; Alternate Delegate, Dr. Roy J. Heffernan, Brookline, Mass.; and Representative to Scientific Exhibit, Dr. Frederick H. Falls, Oak Park, Ill.

The Section sponsored 10 exhibits in the Scientific Exhibit, one of which received a certificate of merit and one an honorable mention. The Section also participated in the Exhibit Symposium on Perinatal Problems and the demonstrations on Resuscitation of the Newborn.

SECTION ON OPHTHALMOLOGY

The Section on Ophthalmology met in the Fairmont Hotel on Tuesday, Wednesday, and Thursday afternoons, June 24, 25, and 26. Nineteen papers were presented as listed in the program. The Section sponsored five sessions of the Association for Research in Ophthalmology, at which 39 additional papers were presented.

At the business meeting on Wednesday, the minutes of the Section for 1957 were approved as published in THE JOURNAL of the A. M. A. Reports of the following representatives from the Section were accepted and submitted to the Board of Trustees for approval:

American Committee on Optics and Visual Physiology
American Board of Ophthalmology
National Registry of Ophthalmic Pathology
Scientific Exhibit
Museum of Ophthalmic History
National Conference on Medical Nomenclature
College of Surgeons, Board of Governors
American Orthoptic Council
Lucian Howe Fund
Research in Ophthalmology and Blindness
Delegate to Pan American Congress of Ophthalmology
Eye Banks
Delegate to House of Delegates
Program Committee

The following appointments, recommended by the Executive Committee, were approved by the Section:

Dr. Gerald Fonda reappointed to the American Committee on Optics and Visual Physiology; Dr. Harold G. Scheie appointed to the American Board of Ophthalmology; Dr. A. B. Reese reappointed to the National Registry of Ophthalmic

Pathology; Drs. Burton Chance, Hans Barken, and Frederick C. Cordes reappointed to the Museum of Ophthalmic History; Dr. Conrad Berens reappointed to the National Conference of Medical Nomenclature; Dr. Edmond L. Cooper reappointed to the American Orthoptic Council; Drs. A. D. Ruedemann and Michael J. Hogan, reappointed to the National Committee for Research in Ophthalmology and Blindness; Dr. James H. Allen reappointed as delegate to the Pan American Association of Ophthalmology;; Drs. F. Phinizy Calhoun Jr. and Ramon Castroviejo reappointed to the Committee on Eye Banks; Drs. Gordon M. Bruce, Arthur G. DeVoe, Lorand V. Johnson, A. Edward Maumenee, Frank W. Newell, T. E. Sanders, and Fred M. Wilson reappointed and Dr. John E. Harris appointed to the Program Committee.

The Section nominated three members, Drs. Arthur Gerard DeVoe, Wendell L. Hughes, and Orwyn H. Ellis for selection of one to serve on the Board of Governors of the American College of Surgeons for the term 1959 to 1962.

Dr. A. D. Ruedemann spoke in behalf of the National Medical Foundation for Eye Care, urging its support. Dr. Trygve Gundersen read the report of the Knapp Testimonial Fund Committee which was accepted by the Section.

Dr. Arthur Bedell presented a motion to thank Dr. Parker Heath for his work on the Knapp Testimonial Fund which was passed.

The following officers were elected: Chairman, Dr. Frank B. Walsh, Baltimore; Vice-Chairman, Dr. Philip M. Lewis, Memphis, Tenn.; Secretary, Dr. Harold G. Scheie, Philadelphia; Assistant Secretary, Dr. Henry F. Allen, Boston; Delegate, Dr. Ralph O. Rychener, Memphis, Tenn., Alternate Delegate, Dr. W. Howard Morrison, and Representative to Scientific Exhibit, Dr. Frank W. Newell, Chicago.

Members of the Committee for the Award of the Knapp Medal were elected as follows: Drs. Charles K. W. Ascher, Chairman; Derrick Vail, and Francis Heed Adler.

The $250 prize for the best scientific exhibit was awarded to Drs. L. K. Garron, M. J. Hogan, W. K. McEwen, and M. L. Feeney, San Francisco, for the exhibit on "Electron Microscopy of Ocular Tissue."

The $250 prize for the best paper was awarded to Dr. Warren A. Wilson, Los Angeles, for his paper on "Galactosemia with Associated Cataracts in Children" judged on the basis of originality and presentation.

The Prize Medal in Ophthalmology was awarded to Dr. Peter C. Kronfeld, Chicago, for his many contributions to ophthalmology.

The Section sponsored 13 exhibits in the Scientific Exhibit, of which one received a certificate of merit and two honorable mentions.

SECTION ON ORTHOPEDIC SURGERY

The Section on Orthopedic Surgery met in the Mark Hopkins Hotel on Tuesday, Wednesday, and Thursday afternoons, June 24, 25, and 26, and jointly with the Section on Physical Medicine on Friday morning, June 27. Seventeen individual papers were presented as listed in the program, in addition to a symposium on "Diagnosis and Treatment of Pain in the Shoulder and Arm" with five papers.

At the business meeting on Tuesday, June 24, the report of the Section Delegate, Dr. N. Relton McCarroll was received. The following resolution was passed for submission to the House of Delegates:

WHEREAS, The Trustees of the American Medical Association have seen fit to publish a manual on the evaluation of injuries; and

WHEREAS, The said manual carries with it the implied approval of the American Medical Association; and

WHEREAS, The aforementioned manual will be freely quoted in medicolegal controversies; and

WHEREAS, In the opinion of the Section on Orthopedic Surgery of the American Medical Association the said manual is in some respects unacceptable; be it therefore

Resolved, That in the near future a revision of the aforementioned manual be made and that such a revision, together with all future American Medical Association publications which touch upon the interests of the individual Sections, be made with the cooperation of the interested Section or Sections through the appointment by them of committees whose function shall be to assist in the guidance and editing of such publications."

At the business meeting on Thursday, June 26, Dr. McCarroll reported that the above resolution had been referred to the Board of Trustees for review.

The following officers were elected: Chairman, Dr. Lenox D. Baker, Durham, N. C.; Vice-Chairman, Dr. H. Herman Young, Rochester, Minn.; Secretary, Dr. Robert J. Joplin, Boston; Assistant Secretary, Dr. John C. Wilson Jr., Los Angeles; Delegate, Dr. H. Relton McCarroll, St. Louis, Mo.; Alternate Delegate, Dr. Harry R. Walker, Oakland, Calif.; and Representative to Scientific Exhibit, Dr. J. I. Kendrick, Cleveland.

The Section sponsored 12 exhibits in the Scientific Exhibit. There were two awards, a certificate of merit and an honorable mention.

SECTION ON PATHOLOGY AND PHYSIOLOGY

The Section on Pathology and Physiology met in Civic Auditorium on Tuesday, Wednesday, and Thursday afternoons, June 24, 25, and 26, the last session being held jointly with the Section on Urology. Nineteen papers were presented, as listed in the program, in addition to which there was a panel discussion on "Carcinoma of the Lower Urinary Tract."

At the business meeting on Wednesday, June 25, the following officers were elected: Chairman, Dr. Thomas M Peery, Washington, D. C.; Vice-Chairman, Dr. Russell L Holman, New Orleans; Secretary, Dr. Hugh A. Edmondson Los Angeles; Delegate, Dr. Lall G. Montgomery, Muncie Ind.; Alternate Delegate, Dr. Oscar Hunter Jr., Washington D. C.; and Representative to Scientific Exhibit, Dr. Samuel A. Levinson, Chicago.

The Section sponsored the Special Exhibit on Fresh Tissue Pathology, as well as 13 individual exhibits. Among the awards were the Hektoen Silver Medal, a certificate of merit, and an honorable mention.

SECTION ON PEDIATRICS

The Section on Pediatrics met in Masonic Temple on Wednesday and Thursday mornings, June 25 and 26, and jointly with the Section on Preventive Medicine on Thursday afternoon, June 26. There were 15 individual papers presented, as well as a symposium on "Competitive Athletics in Children" with five papers.

At the business meeting on Thursday morning, June 26, the following officers were elected: Chairman, Dr. Wyman C. C. Cole Sr., Detroit; Vice-Chairman, Dr. E. Revere Cole, Sacramento, Calif.; Secretary, Dr. Arild E. Hansen, Galveston, Texas; Delegate, Dr. Walter B. Stewart, Atlantic City, N. J., Alternate Delegate, Dr. Russel Mapes, Beverly Hills, Calif., and Representative to Scientific Exhibit, Dr. F. Thomas Mitchell, Memphis, Tenn.; Custodian of Abraham Jacobi Fund, Dr. Hugh Dwyer, Kansas City, Mo.

The Section participated in the Exhibit Symposium on Perinatal Problems in the Scientific Exhibit, as well as in the demonstrations on Resuscitation in the Newborn. There were 15 exhibits sponsored by the Section of which one received a certificate of merit and one an honorable mention.

SECTION ON PHYSICAL MEDICINE

The Section on Physical Medicine met in Masonic Temple on Wednesday and Thursday mornings, June 25 and 26, and in Mark Hopkins Hotel jointly with the Section on Orthopedic Surgery on Friday morning, June 27. Eleven papers were presented as listed in the program, together with a symposium on "Diagnosis and Treatment of Pain in the Shoulder and Arm" with five papers.

At the business meeting on Wednesday, June 25, the following officers were elected: Chairman, Dr. Arthur L. Watkins, Boston; Vice-Chairman, Dr. Lewis A. Leavitt, Houston, Texas; Secretary, Dr. Earl C. Elkins, Rochester, Minn., Delegate, Dr. Walter J. Zeiter, Cleveland; Alternate Delegate, Dr. A. B. C. Knudson, Washington, D. C.; and Representative to Scientific Exhibit, Dr. Harold Dinken, Denver.

The Section nominated the following five diplomates to the American Board of Physical Medicine and Rehabilitation, Drs. Arthur L. Watkins, Boston; Clarence W. Dail, Los Angeles; Thomas F. Hines, New Haven, Conn.; James W. Rae Jr., Ann Arbor, Mich.; and Arthur A. Rodriquez, Chicago, for election of one by said Board to a six-year term to fill the expired term on Dec. 31, 1958, of the Section representative on the American Board of Physical Medicine and Rehabilitation.

The Section sponsored eight exhibits in the Scientific Exhibit of which one received a certificate of merit and one an honorable mention.

SECTION ON PREVENTIVE MEDICINE

The Section on Preventive Medicine met in Masonic Temple on Tuesday afternoon, June 24, jointly with the American Academy of Occupational Medicine; on Wednesday afternoon, June 25, jointly with the Aero Medical Association; and on Thursday afternoon, June 26, jointly with the Section on Pediatrics. In addition to seven papers, there was a symposium on "Occupational Medicine for the Private Practitioner" with five papers and a symposium on "Competitive Athletics in Children" with five papers.

At the business meeting on Tuesday, June 24, the following officers were elected: Chairman, Dr. Robert A. Kehoe, Cincinnati; Vice-Chairman, Dr. Wilford F. Hall, Dayton, Ohio; Secretary, Dr. Frank Princi, Cincinnati; Delegate, Dr. Rutherford T. Johnstone, Los Angeles; and Representative to Scientific Exhibit, Dr. Paul A. Davis, Akron, Ohio.

The Section sponsored 11 exhibits in the Scientific Exhibit of which one received a certificate of merit and one an honorable mention.

SECTION ON RADIOLOGY

The Section on Radiology met in Polk Hall, Civic Auditorium, on Tuesday afternoon, June 24, jointly with the Section on Obstetrics and Gynecology, when two papers were presented, together with a symposium on "Radiation Hazards" with three papers. On Wednesday morning, June 25, the meeting was held in Mark Hopkins Hotel, eight papers being presented. On Thursday morning, June 26, there was a joint meeting with the Section on Diseases of the Chest in California Masonic Memorial Temple with two symposiums.

At the business meeting on Wednesday, June 25, the following officers were elected: Chairman, Dr. Ted F. Leigh, Atlanta, Ga.; Vice-Chairman, Dr. Sydney F. Thomas, Palo Alto, Calif.; Secretary, Dr. Traian Leucutia, Detroit; Delegate, Dr. Eugene P. Pendergrass, Philadelphia; Alternate Delegate, Dr. Earl R. Miller, San Francisco; Representative to Scientific Exhibit, Dr. Richard H. Chamberlain, Philadelphia; and Representative to the American Board of Radiology, Dr. Harold O. Peterson, Minneapolis.

The Section sponsored seven exhibits in the Scientific Exhibit, of which one received a certificate of merit and one an honorable mention.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

The Section on Surgery, General and Abdominal, met in Veterans War Memorial Auditorium, Wednesday, Thursday, and Friday mornings, June 25, 26, and 27, the first session being held jointly with the Section on Anesthesiology. Twelve papers were presented as listed in the program, in addition to a symposium and panel discussion on "Spinal Anesthesia" with six papers.

At the business meeting on Thursday, June 26, the minutes of the 1957 meeting were approved. The Chairman, Dr. Frank Gerbode, commented upon the excellent combined panel with the Section on Anesthesiology on "Spinal Anesthesia." The Secretary, who is also chairman of the American Board of Surgery, read a report concerning the activities of the Board.

The following officers were elected: Chairman, Dr. John H. Mulholland, New York; Vice-Chairman, Dr. Champ Lyons, Birmingham, Ala.; Secretary, Dr. Gustaf E. Lindskog, New Haven, Conn.; Delegate, Dr. Grover C. Penberthy, Detroit; Alternate Delegate, Dr. R. Russell Best, Omaha, Neb.; and Representative to Scientific Exhibit, Dr. Julian Johnson, Philadelphia.

Representatives to the following Boards were also elected: the American Board of Surgery, Dr. J. Garrett Allen, Chicago; the American Board of Neurosurgery, Dr. Frank Mayfield, Cincinnati; and the American Board of Plastic Surgery, Dr. Reed Dingman, Ann Arbor, Mich.

The Chairman outlined tentative plans for the Centennial meeting of the Section in 1959, which will include a centennial honorary lectureship and one afternoon devoted to the history of surgery on the North American Continent.

The Section sponsored 18 exhibits in the Scientific Exhibit. There was one certificate of merit awarded and two honorable mentions. In addition, one exhibit contained material for which a certificate of merit for medical illustration was awarded.

SECTION ON UROLOGY

The Section on Urology met Tuesday and Wednesday afternoons, June 24 and 25, in Masonic Temple, and jointly with the Section on Pathology and Physiology in Civic Auditorium on Thursday afternoon, June 26. Sixteen papers were presented in addition to a panel discussion on "Carcinoma of Lower Urinary Tract."

At the business meeting on Wednesday, June 25, the following officers were elected: Chairman, Dr. Milton M. Coplan, Miami, Fla.; Vice-Chairman, Dr. Thomas A. Morrissey, New York; Secretary, Dr. Edward H. Ray, Lexington, Ky.; Assistant Secretary, Dr. Myron Nourse, Indianapolis; Delegate, Dr. Jay J. Crane, Los Angeles; Alternate Delegate, Dr. Earl Ewert, Boston; Representative to Scientific Exhibit, Dr. E. F. Poutasse, Cleveland; and Assistant Representative to Scientific Exhibit, Dr. Dean Parker, Seattle.

The Section sponsored 22 exhibits in the Scientific Exhibit, one of which failed to arrive from Mexico. There were three awards, consisting of the Billings Silver Medal, a certificate of merit, and an honorable mention. In addition, the Section presented the John H. Morrissey Memorial Award to Drs. George R. Prout, Miami, Fla., Michael Sierp and Willet F. Whitmore Jr., New York, for their exhibit on "Radioactive Zinc in the Male Canine Genitalia."

AWARDS FOR SCIENTIFIC EXHIBITS

The Committee on Awards has made the following report of the awards given at the 1958 Annual Meeting of the American Medical Association.

Hektoen Medal

Hektoen medals, presented to exhibits of original investigation judged on the basis of originality and excellence of presentation, were awarded as follows:

Gold Medal.—Alvin L. Watne, Stuart S. Roberts, Ruth G. McGrath, Elizabeth A. McGrew, and Warren H. Cole, University of Illinois College of Medicine, Chicago, for an exhibit on Cancer Cells in the Circulating Blood.

Silver Medal.—Meyer Texon, New York University Post-Graduate Medical School and Office of the Chief Medical Examiner, City of New York, New York, for an exhibit on the Hemodynamic Concept of Atherosclerosis.

Bronze Medal.—Irving S. Cooper, New York University-Bellevue Medical Center and St. Barnabas Hospital, New York, for an exhibit on Chemopallidectomy for Dystonia and Other Juvenile Involuntary Movement Disorders.

Billings Medal

Gold, silver, and bronze Billings medals were presented to exhibits judged on the basis of excellence of correlation of facts and presentation rather than upon experimental studies:

Gold Medal.—C. H. Hodgson, J. A. Callahan, A. J. Bruwer, and A. H. Bulbulian, Mayo Clinic and Mayo Foundation, Rochester, Minn., for an exhibit on Misleading Thoracic Roentgenograms.

Silver Medal.—Roderick D. Turner, University of California Medical Center, Los Angeles, for an exhibit on Surgical Technique and Uses of Isolated Intestinal Segment in Urological Surgery.

Bronze Medal.—Julio C. Davila, Robert G. Trout, Joseph E. Sunner, and Robert P. Glover, The Thoracic and Cardiovascular Research Laboratory at Presbyterian Hospital, Philadelphia, for an exhibit on Cardiac Valvular Dynamics: Anatomic, Physiologic and Pathologic Studies.

Section Awards

Certificates of Merit and Honorable Mention were awarded to the following exhibits in each section.

Section on Anesthesiology

Certificate of Merit to Dante Bizzarri and Joseph Giuffrida, Columbus and Elmhurst General Hospitals, and New York Medical College, New York, for the exhibit on Continuous Monitoring of Circulation During Surgery.

Honorable Mention to John Adriani and Bobby Smith, Charity Hospital and Louisiana State University School of Medicine, New Orleans, for the exhibit on Respiratory Stimulants.

Section on Dermatology

Certificate of Merit to Eugene P. Schoch Jr., Austin, Texas, and Arthur G. Schoch and Lee J. Alexander, Southwestern Medical School Dallas, Texas, for the exhibit on Pruritus: A Review of Etiology and Treatment.

Honorable Mention to Arthur S. Spangler, Harvard Medical School, Massachusetts General and Peter Bent Brigham Hospitals, Boston, for the exhibit on Fibrin Foam Treatment of Depressed Scars.

Section on Diseases of the Chest

Certificate of Merit to William L. Watson, Ulrich K. Henschke, William G. Cahan, Eugene E. Cliffton, John T. Goodner, Raymond J. Luomanen, and John L. Pool, Memorial Center for Cancer and Allied Diseases, New York, for the exhibit on Lung Cancer: Management by Interstitial Irradiation.

Honorable Mention to Gustav J. Beck, Columbia University College of Physicians and Surgeons and Presbyterian Hospital, New York, for the exhibit on a Physiological Approach to the Medical Management of Bronchopulmonary Disease.

Honorable Mention to George D. Geckeler, William Likoff, R. C. Truex, Henry T. Nichols, Houck E. Bolton, Dryden P. Morse, Joseph F. Uricchio, Harry Goldberg, Clemente Oca, Jacob Zimmerman, and Charles P. Bailey, Bailey Thoracic Clinic and Hahnemann Medical College and Hospital, Philadelphia, for the exhibit on the Significance of the Fibrous Skeleton of the Heart in Mitral Valve Surgery.

Section on Experimental Medicine and Therapeutics

Certificate of Merit to Myron Prinzmetal, Rexford Kennamer, Naci Bor, and Takashi Wada, Institute for Medical Research, Cedars of Lebanon Hospital and University of California School of Medicine, Los Angeles, for the exhibit on Coronary Artery Disease: New Clinical and Experimental Observations.

Honorable Mention to Marvin John Seven and L. Audrey Johnson, Hahnemann Medical College and Hospital of Philadelphia, Philadelphia, for the exhibit on What Is Chelation? Medical Applications of Metal-binding Agents.

Honorable Mention to Hubert C. Peltier, Harold L. Upjohn, Robert O. Stafford, and Robert H. Levin, The Upjohn Company, Kalamazoo, Mich., for the exhibit on Relation of Steroid Structure to Function: Improvement on Natural Steroids Through Alteration of Chemical Structure.

Section on Gastroenterology and Proctology

Certificate of Merit to Francis M. Spencer, San Angelo Medical and Surgical Clinic, San Angelo, Texas, and Lee S. Monroe, Scripps Clinic and Research Foundation, LaJolla, Calif., for the exhibit on Color Photomicrographs in Teaching Recognition of the Intestinal Parasites.

Honorable Mention to J. L. Bollman, F. F. Whitcomb Jr., H. N. Hoffman II, and H. R. Butt, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Bile Pigments of Icteric Serum.

Honorable Mention to George Kulick and Louis M. Rousselot, St. Vincent's Hospital, New York, for the exhibit on Automatic Tamponade Controls for Bleeding Esophagogastric Varices.

Section on General Practice

Certificate of Merit to E. D. Bayrd and A. B. Hagedorn, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Blood Smears: Their Value in General Diagnosis.

Honorable Mention to W. D. Snively Jr., Michael J. Sweeney, and M. L. Wessner, St. Mary's Hospital, Evansville, Ind., for the exhibit on Clinical Pictures of Fluid Imbalances.

Honorable Mention to Paul Q. Peterson, S. D. Pomrinse, and Bernard D. Daitz, Chronic Disease Program, Public Health Service, and Josephine J. Buchanan, District of Columbia General Hospital, Washington, D. C., for the exhibit on Strike Back at Strokes: Early Mobilization of the Stroke Patient.

Members of the Committee on Awards are Drs. Frank B. Queen, Portland, Ore., Chairman; William B. Condon, Denver; Louis B. Newman, Chicago; Henry H. Turner, Oklahoma City; and J. Walter Wilson, Los Angeles.

Section on Internal Medicine

Certificate of Merit to Douglass H. Howry, Joseph H. Holmes, Gerald J. Posakony, and Richard Cushman, University of Colorado School of Medicine, Denver, for the exhibit on Visualization of Living Soft Tissue Structures by Ultrasonic Methods.

Honorable Mention to Penn G. Skillern, Marvin Clamen, E. Perry McCullagh, and Otto Glasser, Cleveland Clinic, Cleveland, for the exhibit on Radioiodine for Diagnosis and Therapy of Hyperthyroidism due to Adenomatous Goiter.

Honorable Mention to Ralph V. Ford, Charles L. Spurr, John H. Moyer, Carroll A: Handley, and J. B. Rochelle, Baylor University College of Medicine and Veterans Administration Hospital, Houston, Texas, for the exhibit on Diuretic Therapy.

Section on Laryngology, Otology, and Rhinology

Certificate of Merit to Joel J. Pressman and Mildred Burtz Simon, University of California at Los Angeles School of Medicine, Los Angeles, for the exhibit on Repair of Cervical Trachea and Esophagus by Aortic Homografts.

Honorable Mention to J. Brown Farrior, Southern Foundation, Tampa, Fla., for the exhibit on Mobilization or Fenestration: Pathological Indications in 3-D.

Honorable Mention to Victor Goodhill, Arthur L. Holcomb, Seymour J. Brockman, and Irwin Harris, Deafness Research Laboratory, Children's Hospital, Cedars of Lebanon Hospital, and University of Southern California School of Medicine, Los Angeles, for the exhibit on Monitored Stapes Mobilization: Peribasal Approach.

Section on Military Medicine

Certificate of Merit to Eli L. Beeding Jr., Holloman Air Force Base, New Mexico, for the exhibit on Human Tolerance to Mechanical Forces.

Honorable Mention to Maurice R. Hilleman, Walter Reed Army Institute of Research, Walter Reed Army Medical Center, Washington, D. C., for the exhibit on Asian Influenza: Identification, Diagnosis, and Vaccination.

Honorable Mention to Jerome J. De Cosse, Benjamin H. Gaston, Wilfred T. Tumbusch, and Edward H. Vogel Jr., U. S. Army Surgical Research Unit, Brooke Army Medical Center, Fort Sam Houston, Texas, for the exhibit on the Initial Care of the Severely Burned Patient.

Section on Nervous and Mental Diseases

Certificate of Merit to R. V. Randall, E. C. Clark, H. W. Dodge Jr., R. C. Bahn, and Arthur H. Bulbulian, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Diabetes Insipidus: Current Concepts in the Production of Antidiuretic Hormone with Clinical and Experimental Observations.

Honorable Mention to John A. Wagner, and Rafael Longo-Cordero, University of Maryland School of Medicine, Baltimore, for the exhibit on Let's Do Away with "CVA."

Honorable Mention to A. E. Bennett, G. L. Mowery, and Joel Fort, Herrick Memorial Hospital, Berkeley, Calif., for the exhibit on Alcoholic Brain Disease.

Section on Obstetrics and Gynecology

Certificate of Merit to James S. Krieger and Lawrence J. McCormack, Cleveland Clinic, Cleveland, for the exhibit on Cervical Carcinoma in-Situ: the Role of Radical Conization.

Honorable Mention to Edward T. Tyler and Henry J. Olson, University of California at Los Angeles School of Medicine, Los Angeles, for the exhibit on Fertility-Promoting and Anti-Fertility Effects of New Steroids.

Section on Ophthalmology

Certificate of Merit to L. K. Garron, M. J. Hogan, W. K. McEwen, and M. L. Feeney, University of California Medical Center, San Francisco, for the exhibit on Electron Microscopy of Ocular Tissue.

Honorable Mention to Dan M. Gordon, New York Hospital, Cornell Medical Center and The L. Margolyes League, New York, for the exhibit on Common Ocular Problems.

Honorable Mention to George K. Smelser and George D. Pappas, Columbia University College of Physicians and Surgeons, New York, for the exhibit on Electron Microscopy of the Epithelium of the Ciliary Body.

Section on Orthopedic Surgery

Certificate of Merit to Joseph L. Fleming, Christopher Glenney, Jerome Stroot, and Victor Zackay, Henry Ford Hospital, Detroit, for the exhibit on Experimental Knee Arthroplasty: a study of the Effect of Various Interposing Membranes.

Honorable Mention to Donald S. Miller and Rowlin L. Lichter, Chicago Medical School and Cook County Hospital, Chicago, for the exhibit on Circulatory System Changes Associated with Orthopedic Conditions (by Decades).

Section on Pathology and Physiology

Certificate of Merit to Henry C. Sweany, David F. Gorelick, Fred C. Coller, and James L. Jones, Missouri State Sanatorium, Mount Vernon, Miss., for the exhibit on Pathology and Pathogenesis: Subacute and Chronic Pulmonary Histoplasmosis.

Honorable Mention to Edward H. Johnston, Armed Forces Institute of Pathology, Washington, D. C., Paul F. Guerin and Russell S. Fisher, Office of Chief Medical Examiner, Baltimore, for the exhibit on the Medicolegal Autopsy: Obscure and Unusual Causes of Unexpected Death.

Section on Pediatrics

Certificate of Merit to Willard R. Centerwall and Siegried A. Centerwall, College of Medical Evangelists, Los Angeles, for the exhibit on Early Diagnosis and Management of Phenylketonuria.

Honorable Mention to Simon Kove, Stanley Goldstein, Ralph E. Perry, and Felix Wróblewski, New York University College of Medicine and Sloan-Kettering Institute, Memorial Center, New York, for the exhibit on Diagnosis of Neonatal Jaundice by Serum Transaminase.

Section on Physical Medicine

Certificate of Merit to F. J. Kottke and W. G. Kubicek, University of Minnesota Medical School, Minneapolis, for the exhibit on Cardiac and Metabolic Demands During Rehabilitation Procedures: Methods and Results.

Honorable Mention to W. D. Paul and David M. Paul, University of Iowa and Veterans Administration Hospital, Iowa City, for the exhibit on Ankle Sprains: Prevention and Treatment.

Section on Preventive Medicine

Certificate of Merit to Morris Goldman, Max D. Moody, Robert A. Goldwasser, and Theodore R. Carski, Communicable Disease Center, Public Health Service, U. S. Department of Health, Education, and Welfare, Atlanta, Ga., for the exhibit on Rapid Diagnosis with Fluorescent Antibody.

Honorable Mention to Peter Safar, Baltimore, James O. Elam and David G. Greene, Buffalo, U. S. Army Medical Service, for the exhibit on Respiratory Resuscitation.

Section on Radiology

Certificate of Merit to I. E. Kirsh and J. F. Kinney, Veterans Administration Hospital, Hines, Ill., for the exhibit on Roentgen Diagnosis of Mitral Stenosis.

Honorable Mention to William Molnar, Sidney W. Nelson, Karl P. Klassen, and Joseph M. Ryan, Ohio State University Hospital, Columbus, Ohio, for the exhibit on Aortic Valvulography and Ascending Aortography.

Section on Surgery, General and Abdominal

Certificate of Merit to C. W. Lillehei, H. E. Warden, R. A. DeWall, V. L. Gott, P. C. Hodges, P. Adams, R. C. Anderson, R. L. Varco, and O. H. Wangensteen, University of Minnesota Medical School, Minneapolis, for the exhibit on Management of the Candidate for Open Heart Surgery.

Honorable Mention to C. W. Mayo, J. M. Waugh. E. S. Judd Jr., B. M. Black, G. A. Hallenbeck, and O. H. Beahrs, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Surgical Management of Carcinoma of the Rectum and Rectosigmoidal Region.

Honorable Mention to Howard H. Steel, Kenneth M. Schreck, H. Taylor Caswell, Norman Learner, R. Robert Tyson, and Elsie R. Carrington, Temple University Medical Center, Philadelphia, for the exhibit on Staphylococcal Hospital Infections.

Section on Urology

Certificate of Merit to Hans Elias, Chicago Medical School, Chicago, for the exhibit on New Concepts Concerning the Structure of the Nephron.

Honorable Mention to Vernon H. Youngblood, Edwin M. Tomlin, and Jerome O. Williams, Concord, N. C., for the exhibit on Exfoliative Cytology of the Senile Female Urethra.

Section on Miscellaneous Topics

Certificate of Merit to Thomas S. Masterson, Verlin Y. Yamamoto, and Joseph K. Brown, Biological Photographic Association, New York, for the exhibit on Medical Photography: an Aid to Medical Education.

Honorable Mention to Hooker Goodwin, Angela Bartenbach, and Gladys McHugh, Association of Medical Illustrators, Chicago, for the exhibit on Medical Illustration of Today.

Exhibit Symposium on Arthritis and Rheumatism

Certificate of Merit to Charley J. Smyth, Robert L. Johnson, and Glenn M. Clark, University of Colorado School of Medicine, Denver, for the exhibit on Evaluation of Therapy in Rheumatoid Arthritis.

Honorable Mention to Bernard M. Norcross and Salvatore R. La Tona, University of Buffalo School of Medicine and Buffalo General Hospital, Buffalo, for the exhibit on Diseases of the Connective Tissues.

Medical Photography

A special certificate for the effective use of photography in the presentation of medical information to Fred W. Kent, James A. Kent, and Jack Davis, Iowa City. This award is newly introduced in recognition of the importance of medical photography in visual education, and is presented for the photography which appears in the exhibit on Ulcerative Colitis by J. A. Clifton, R. C. Hickey, G. H. M. Thornton, and R. T. Tidrick, State University of Iowa, Iowa City.

Medical Illustration

A special certificate in the field of medical illustration to Barbara Allison and Verlin Y. Yamamoto, Des Moines, Iowa, for the well-illustrated exhibit on Upper Dorsal Sympathectomy by Louis T. Palumbo, Veterans Administration Center, Des Moines.

Honorable Mention to Alfred Teoli and William Stone, San Francisco, for medical illustration in the exhibit on The Gastric Analysis by J. Alfred Rider, Hugo C. Moeller, Joyce Swader, Lourdes O. Agcaoili, Richard G. Devereaux, Jennie Lee, Ernesto Puletti, and John O. Gibbs, University of California Medical Center, San Francisco.

Honorable Mention to Gerald P. Hodge, Ann Arbor, Mich., for medical ilustration in the exhibit on Correction of Intracardiac Defects by Herbert Sloan, Joe D. Morris, and Aaron Stern, University of Michigan Medical School, Ann Arbor.

Special Exhibits

The Committee on Awards commended the continuous high quality of the special exhibits on Fractures, Pulmonary Function, and particularly the development of physical examinations for physicians under the Section on General Practice.

Science Fair and Student A. M. A. Exhibits

The Committee on Awards commended the high quality of the exhibits presented by the two teen-age Science Fair exhibitors, and the two Student A. M. A. exhibitors.

History of Medicine

The Committee on Awards commended Parke Davis & Company, Detroit, Mich., for its outstanding paintings on Epics in Medical History which were presented in the main corridor of The Scientific Exhibit, and also the outstanding exhibits on medical history, namely, A Century of Naval Medicine presented by the United States Navy and E. R. Squibb & Sons, and the History of the Medical Department, U. S. Army in World War II, presented by John Boyd Coates Jr., of the U. S. Army Medical Service, Walter Reed Army Medical Center, Washington, D. C.

Comments

To the many persons involved in the preparation and demonstration of exhibits and to the Section Representatives for their assistance, the Committee on Awards wishes to give its thanks.

The Committee on Awards commends Dr. Thomas G. Hull and his staff for their efforts throughout the year in planning and arranging this outstanding Scientific Exhibit.

ABSTRACTS ON ABSENCE FROM WORK

A future issue of THE JOURNAL will carry an article entitled, "Abstracts on Absence from Work and Its Relation to Private Practice." Prepared as part of the continuing activity of the Committee on Medical Care for Industrial Workers in this field, this article reflects some of the current opinions and attitudes toward the problem of work absence.

The abstracts have been combined in such a manner as to portray the wide range of interest in the area of absence from work, the problems involved in evaluating the causes and extent of absence due to nonoccupational illness and injury, and factors which concern the private practitioner as they relate to the certification of illness. The picture as evolved by the article calls for a teamwork approach by management and medical personnel, as well as the individual affected, in order "to assist in a clearer understanding of the causes of work absence."

The introduction to the article stresses the important role of the private physician in finding and certifying health conditions justifying absence and in returning his patient to work at the earliest opportunity. It points out that, "The failure of the private physician to participate in efforts by industry to evaluate absence from work may only result in unsatisfactory programs for all concerned."

COUNCIL ON MEDICAL SERVICE

COMMITTEE ON MEDICAL CARE FOR INDUSTRIAL WORKERS

A Preliminary Guide for Measuring Work Absence due to Illness and Injury.—The subject of work absence has always been an area of interest and activity of the Committee on Medical Care for Industrial Workers. The Committee has conducted several studies, held conferences, and published various types of materials on this subject, which have created a considerable amount of interest.

The Committee's major contribution was made in 1956 through sponsorship of a conference on absence from work due to nonoccupational illness and injury. Over 500 persons from the medical and allied professions active in this field attended and attempted to summarize existing knowledge of problems related to absence from work. One of the recommendations of the Conference was that the Committee on Medical Care for Industrial Workers "establish and recommend practices and procedures on the fundamentals of basic morbidity record-keeping systems."

With the advice of experts on both medical and management levels concerned with work absence, the Committee has just published a Preliminary Guide for Measuring Work Absence due to Illness and Injury. This Guide contains various definitions and formulas which the Committee hopes will serve as a foundation for the uniform collection of sickness absence statistics. The Guide is a preliminary one in that the Committee hopes to be able to revise it according to the suggestions and experience of persons who will be using it, and thereby modify it in future editions so that it will ultimately serve as a basic reference work in this field. Future revisions of this Guide will also contain a recommended nomenclature which the Committee has not attempted to formulate with this printing of the Guide.

The 11-page booklet, available on request without charge, contains a "comment and suggestion form" which the Committee hopes will be used by medical and other personnel to provide it with suggestions for future consideration in revising the Guide.

1958 Survey of Union Health Centers.—A third Survey of Union Health Centers has recently been completed by the Committee on Medical Care for Industrial Workers. The survey, to be issued in publication form in the near future, will contain descriptions of 28 health centers. They represent more than half of the 50 union health centers in operation as of the end of 1957; their membership represents almost 80% of the 950,000 persons enrolled in all union health centers.

The Survey treats each union health center as a specific case study, and for each plan includes information and data on (1) history; (2) membership; (3) objectives of programs; (4) facilities; (5) financing; (6) budget and operating costs; (7) administration; (8) business and professional personnel; (9) benefits; and (10) preventive aspects of these services.

Some of the highlights of the survey findings are as follows:

—Ten of the 28 plans surveyed, with an enrollment of approximately 530,000, cover one or more dependents; 3 of these also cover retired members.

—The programs of 22 of the 28 union health centers were participated in and supported by 482 local unions; over 4,800 firms were involved in the collectively bargained agreements supporting the programs of 18 union health centers.

—Seventeen of the 28 centers provide diagnostic and ambulatory medical care, 10 provide diagnostic services only, and one offers comprehensive medical care.

—Over 1,100 physicians were employed in 27 of the 28 programs, most of them on an hourly or per-session basis; in a few instances physicians in private group practice rendered specific services to members and, in some instances, to dependents of union members.

—Hourly rates for general practitioners ranged from $5.75 to $10 per hour; specialists received from $7 to $12 per hour.

Joint Committee of the Council on Medical Service and the Council on Industrial Health.

–Yearly utilization ranged from a low of 5.5% in one plan to a high of 89.2% in another plan; in 11 plans it ranged from 31 to 50%.

–Collective bargaining represents the prime source of monies for which support of 24 of the 28 centers is received.

COMMITTEE ON FEDERAL MEDICAL SERVICES

VA Insurance Cases–New Action.–The Veterans' Administration is authorized, by law, to provide care for veterans with non-service-connected disabilities, within the limits of available facilities–if the veteran is unable to pay for care. The only measure of the veteran's ability to pay mentioned in the law is his statement, under oath, that he cannot pay for the necessary hospitalization and medical care.

With this as authority, the VA has, for many years, provided hospital and medical care for veterans with various types of health insurance and for veterans with disabilities covered by workmen's compensation coverage. Not only has it provided such care but also it has billed the insurers for such care. In fiscal year 1955, for example, the VA reported receipts of almost 4 million dollars from nonfederal sources; the "major portion" of these receipts, according to the VA, consisted of "proceeds from hospitalization contracts."

At its Seattle session in November, 1956, the House of Delegates of the American Medical Association adopted resolutions condemning this practice as "unlawful" (since insured patients should not be considered as "unable to pay for care") and "a definite violation of the ethical principles governing the practice of medicine" (since billing insurance companies for this care involves the federal government in medical practice on a fee-for-service basis). The resolutions were referred to the Council on Medical Service for action.

On June 26, 1957, the VA took a first step in the direction of curtailing this type of care. It instructed hospital administrators, when a veteran's non-service-connected disability is covered by workmen's compensation or similar industrial accident insurance, to so notify the veteran and urge him to request transfer to a non VA hospital. If he refuses, his file is to be sent to the VA central office, for possible referral to the Department of Justice. No action was taken at that time in regard to other insured veteran patients.

On July 30, 1958, Rep. Olin E. Teague (D., Texas), Chairman of the House Committee on Veterans' Affairs, reported a bill, H. R. 10028, to the House. This bill deals entirely with the medical care aspects of the Veterans' Administration's operations, and includes several provisions concerning workmen's compensation and insured cases.

First, it would require the veteran to fill out a complete statement of his assets and liabilities, as a guide to determining whether or not he can pay for care. In short-term cases (less than 30 days), the VA hospital manager is to inform the applicant of the cost of necessary care in local nonfederal hospitals, and urge reconsideration of the statement of inability to pay. The statement of assets would include a listing of any health insurance held by the veteran (though not of any income of his wife or other responsible relatives).

This statement of assets is already being used in VA hospitals, but the proposed bill would make it a matter of law, rather than of administrative regulation.

Secondly, the bill would give veterans with disabilities covered by workmen's compensation or health insurance the lowest priority for admission of all non-service-connected patients. These applicants could be refused admission so long as any other veteran is on a waiting list for admission to the same facility. This system of priorities had, in effect, already been established in the VA for the workmen's compensation cases, but the bill would give statutory recognition to the practice and would include insured cases.

It should be noted that this priority system would by no means eliminate the VA practice of admitting these patients, since insured applicants would still be admitted if there were no noninsured applicants on the waiting list.

It should also be noted that the House Committee makes no mention, in its report accompanying the bill, of the ethical questions involved; it does not even discuss the question of whether these applicants can truly be considered "unable to pay" or whether the VA can properly bill insurers for medical care. The reasons actually given for the proposed amendment are, first, that veteran patients with insurance who do not use it are depriving veterans who do not have such coverage and, second, that the VA cannot collect on most such insurance, anyway.

In this connection, the report gives some very interesting figures on VA patients. In fiscal year 1953, about 52,200 of the patients discharged by the VA had hospital insurance, and the VA collected a little over 3 million dollars for care provided; in 1957, over 73,000 patients were insured, but the VA collected only $2,700,000. The amount collected per case has gone down about one-third–but the number of patients with insurance has increased by one-half!

The proposed amendments, insofar as they concern admission of insured patients, do not represent full implementation of the stated policy of the medical profession, but they do indicate that this policy is receiving serious consideration and may represent a step toward a realistic appraisal of the veteran's ability to pay for care.

COUNCIL ON NATIONAL DEFENSE

There has been a steady decline in applicants applying for a reserve commission and subsequent active military duty. The Selective Service System might be called upon to obtain physicians on a special draft call after July 1, 1959. The Council is making the following report as a subject of interest to all young physicians who have a draft liability under the provisions of the Universal Military Training and Service Act. FRANK W. BARTON, *Secretary.*

PHYSICIANS SUBJECT TO DRAFT CALL IN 1959

The last special call for induction of physicians by the Selective Service System was made in October, 1955, for 297 physicians for active military service commencing in February, 1956. Since that call, the military requirements for physicians have been filled through voluntary applicants of young physicians for reserve commissions under the Berry Plan. Under that plan, deferments for internship and residency training are given to physicians making application for a reserve commission with subsequent active duty callup.

Under the current law, only physicians up to age 35 who are liable under the general draft law have a military obligation.

On Sept. 22, 1958, the Selective Service System advised local draft boards that too few physicians are volunteering for active duty to meet service requirements and that, if the present trend continues, a special call for physicians might be necessary. Local boards are expected, in anticipation of a possible special call for physicians (but not dentists), to proceed with the physical examination of all physicians in class I-A or class I-A-0 if they have not been examined.

The Department of Defense estimates it will need 1,000 intern volunteers for the Berry Plan to meet its medical requirements next summer. As of Oct. 1, 1958, there was still a deficit of some 600 intern applicants out of 5,400 interns who are liable for military service. The deadline of Sept. 15, 1958, has been extended for interns desiring to apply for a reserve commission and active duty following internship. If sufficient volunteers are not forthcoming in the next few months, the Department of Defense will be forced to place a call with Selective Service for physicians for active duty after July, 1959.

An upturn in the rate of residents volunteering under the Berry Plan in the past few weeks has satisfied the anticipated military requirements in all specialties except otolaryngology and psychiatry. About 900 residents have received reserve commissions. The Council is informed that some physicians have applied for immediate active duty and have been turned down by the Army because their deficit for 1959 is quite small.

All interns who applied prior to Sept. 15 may go on active duty at the completion of their internship early next summer. Some of those who subsequently volunteer also will have that privilege if they so wish, but others will have to wait until September or later in the fall of 1959.

MEDICAL CIVIL DEFENSE CONFERENCE

The Council on National Defense, American Medical Association, is sponsoring the ninth annual conference of the County Medical Societies Civil Defense Organization. The conference will be held at the Morrison Hotel, Chicago, on Nov. 8 and 9, 1958.

The Program

These yearly conferences are planned to inform and otherwise assist medical and health personnel for their respective roles in disasters. Conferees have the opportunity (1) to participate in workshop sessions concerning medical preparedness to cope with disasters, (2) to discuss and exchange information dealing with emergency medical services, (3) to be informed on the availability of pamphlets and articles devoted to the medical and health aspects of civil defense, and (4) to hear outstanding speakers report on appropriate civil defense and disaster topics.

A realistic test exercise involving simulated disasters is the best method, short of the real thing, to determine the operational capabilities and adequacy of emergency medical and health plans and programs. The conference this year will feature reports on the experience gained from three such test exercises.

Those desiring additional information about the conference are requested to contact Mr. Frank W. Barton, Secretary, Council on National Defense, American Medical Association, 535 N. Dearborn St., Chicago 10.

SATURDAY—NOV. 8, 1958
COTILLION ROOM, MORRISON HOTEL

8:00- 9:00	*Registration*
9:00- 9:05	Call to Order Edward G. Sharp, M. D.
9:05- 9:15	Welcome Address F. J. L. Blasingame, M. D.
9:15- 9:30	The A. M. A. CD Program Carroll P. Hungate, M. D.
9:30-10:00	The Federal CD Program—OCDM Honorable Leo A. Hoegh
10:00-10:20	National Medical Preparedness—OCDM (Speaker to be selected)
10:20-10:40	Biological and Chemical Warfare Paul A. Lindquist, M. D.
10:40-11:00	Intermission
11:00-11:30	California CPX—Medical and Welfare Services Frank F. Schade, M. D.
11:30-12:00	Operation Prep Pitt Francis C. Jackson, M. D.
12:00-12:30	General Public Health Problems in Civil Defense Lieut. Col. Ingalls H. Simmons, M. C., U. S. Army.
12:30- 2:00	Luncheon—Embassy Room
2:00- 5:15	Workshop Session Conferees to be divided into four groups to consider specific problems and recommended courses of action in "Planning for Mass Casualty Care." Orientation and Assignments—Cotillion Room Edward G. Sharp, M. D. I Organization and Training Group Leader—James H. Lade, M. D. Advisor—William H. Reiff, M. D. II Reception, Evacuation, and Emergency Care Group Leader—Harold C. Lueth, M. D. Advisor—(to be selected) III Hospital Disaster Planning Group Leader—Max L. Lichter, M. D. Advisor—John N. Hatfield II IV Supplies, Transportation, and Communication Group Leader—Lester M. Petrie, M. D. Advisor—Charles P. Anderson, M. D.
6:00- 7:00	Social Hour

SUNDAY—NOV. 9, 1958

9:00- 9:30	A. M. A. Special Study Project Report Earle Standlee, M. D.
9:30-10:30	Workshop Session Reports Harold C. Lueth, M. D., Presiding.
10:30-11:00	Operation Test Star Burton E. Adams, M. D.
11:00-11:15	Intermission
11:15-11:45	Operation AFTA John K. Hampton Jr., Ph.D.
11:45-12:00	The Profession's CD Responsibilities Gunnar Gundersen, M. D.
12:00-12:30	*OCDM Shelter Habitability Program* Paul S. Parrino, M. D.
12:30- 2:00	Luncheon—Embassy Room
2:00- 2:30	Selected Movies
2:30- 2:45	Resuscitation Techniques Robert A. Hingson, M. D.
2:45- 3:00	The CD Role of Dentists Russell W. Bunting, D.D.S.
3:00- 3:15	The CD Role of Nurses Catherine M. Sullivan, R. N.
3:15- 3:45	Business Session—Adjournment Edward G. Sharp, M. D., Presiding.

PARTICIPANTS

Burton E. Adams, M. D., Member, Committee on Civil Defense, Alameda-Contra Costa Medical Association, San Leandro, Calif.

Charles P. Anderson, M. D., Deputy Commissioner, Medical Services, City of Detroit, Department of Healt Detroit.

F. J. L. Blasingame, M. D., Executive Vice-presiden American Medical Association, Chicago.

Russell W. Bunting, D.D.S., Dental Consultant, Offic of Civil and Defense Mobilization, Battle Creek, Mich.

Gunnar Gundersen, M. D., President, American Medic Association, La Crosse, Wis.

John K. Hampton Jr., Ph.D., Associate Professor i Physiology, School of Medicine, Tulane University, Ne Orleans.

John N. Hatfield II, Assistant Administrator, Burlingto County Hospital, Mount Holly, N. J.

Robert A. Hingson, M.D., Professor of Anesthesia, Western Reserve University, School of Medicine, Cleveland.

Honorable Leo A. Hoegh, Director, Office of Civil an Defense Mobilization, Washington, D. C.

Carroll P. Hungate, M.D., Member, Council on Nationa Defense and Committee on Civil Defense, American Medical Association, Kansas City, Mo.

Francis C. Jackson, M.D., Chief of Surgery, Veteran Administration Hospital, Pittsburgh.

James H. Lade, M.D., Director, Office of Medical Defense, New York State Department of Health, Albany, N. Y

Max L. Lichter, M.D., Member, Committee on Civi Defense, Council on National Defense, American Medica Association, Detroit.

Paul A. Lindquist, M.D., Director, Health Division Plans and Readiness Office, Office of Civil and Defens Mobilization, Battle Creek, Mich.

Harold C. Lueth, M.D., Chairman, Committee on Civi Defense, Council on National Defense, American Medica Association, Evanston, Ill.

Paul S. Parrino, M.D., Director, Biophysical and Medical Sciences Office, Office of Civil and Defense Mobilization, Battle Creek, Mich.

Lester M. Petrie, M.D., Director, Preventable Disease Service, Department of Public Health, State of Georgia Atlanta, Ga.

William H. Reiff, M.D., Chairman, Civil Defense, Oklahoma State Medical Association, Oklahoma City, Okla.

Frank F. Schade, M.D., Chief, Medical and Healt Section, Los Angeles County and Cities Civil Defense Planning Board, Los Angeles.

Edward G. Sharp, M.D., Chairman, Civil Defense Committee, *Philadelphia County Medical Society, Philadelphia*

Ingalls H. Simmons, Lieut. Col., M. C., U. S. A., Director, Department of Preventive Medicine, Army Medical Service School, Fort Sam Houston, Texas.

Earle Standlee, M.D., Director, Commission on a National Emergency Medical Care Plan, American Medical Association, Chicago.

Catherine M. Sullivan, R.N., Nurse Consultant, Office of Civil and Defense Mobilization, Battle Creek, Mich.

MEDICAL NEWS

ARKANSAS

Construct Children's Colony at Conway.—Construction has started on the first phase of a building program for the Arkansas Children's Colony at Conway, according to David B. Ray Jr., superintendent. The state is said to be one of two that have no state facilities for the mentally retarded. Located about 33 miles from Little Rock, the site contains 406 acres. The overall building program is that for a new community planned for children with the aim to create a homelike atmosphere. There will be a central group of buildings and nearby, eight children's cottages, each with its own serving kitchen, dining room, day room and play yard. The initial construction will accommodate 256 children, with 32 living in each cottage. Facilities for 1500 will eventually be completed. Future expansion of the central area will include chapel, auditorium, gymnasium, children's store and other facilities. Only educable and trainable children aged 6 to 18 will be enrolled initially. The Colony's budget provides for four trainee positions for advanced students in psychology, education, social work and other professional areas.

CALIFORNIA

Associate Deans at Stanford.—Dr. Lowell A. Rantz, professor of medicine became associate dean of Stanford University School of Medicine Sept. 1, joining two other associate deans, Lyle E. Cook and Dr. Lyman M. Stowe, and replacing Dr. Jay Ward Smith, who resigned to resume private practice. Dr. Rantz will assist Dean Alway in the administration of medical affairs and professional relations both inside and outside the Medical School. He will continue his teaching, research, and clinical activities in the department of medicine.

Society News.—The officers of the Los Angeles Obstetrical and Gynecological Society, Inc. for 1958 are: Dr. Alphonsus M. McCarthy, president; Dr. Dan Golenternek, vice-president; and Dr. John L. Gaspar, 16100 Ventura Boulevard, Encino, Calif. (STate 4-8251), secretary-treasurer.——The 1958-59 officers of the Los Angeles Radiological Society are: president, Dr. Lewis J. Peha, Los Angeles; vice-president, Dr. Putnam C. Kennedy, Glendale; secretary, Dr. Robert B. Engle, Pasadena; treasurer, Dr. Robert E. Rickenberg, Los Angeles; and member of the executive committee (3 years), Dr. Richard A. Kredel, Pasadena. The society meets the second Wednesday of September, November, March, April, and June, at the Los Angeles County Medical Association Building.

GEORGIA

Grant to Poliomyelitis Center.—A grant of $65,545 has been made by The National Foundation (formerly the National Foundation for Infantile Paralysis) in continuing support of the work of the Southeastern Poliomyelitis Respiratory and Rehabilitation Center at the Medical College of Georgia during the year from July 1, 1958, through June 30, 1959. The center, one of 17 in the United States, is continuing its program of study and treatment of paralyzed children and adults from throughout the South. An active teaching program is made available to physicians, medical students. The staff of the center is surveying the problems of polio respirator patients in their homes throughout the southeastern states, and offering assistance to their families and physicians.

ILLINOIS

Chicago

George H. Coleman Medal Established.—The Institute of Medicine of Chicago has established the George Howell Coleman medal as a tribute to Dr. Coleman, who has been a devoted secretary of the Institute for nearly 25 years. The medal is to be awarded to "a physician or kindred scientist who has rendered outstanding service to the community above and beyond the practice of his profession." Dr. Coleman will be the recipient of the first Coleman medal, which will be presented at a dinner at the Drake Hotel, Oct. 27.

Dr. Coleman graduated from Rush Medical College and was the last assistant trained by the late Dr. Frank Billings. He has been an associate of Dr. Joseph A. Capps, is senior consulting physician at St. Lukes Hospital, a member of the Board of Directors of the Blue Shield Plan, and was a member of the organizing committee of the Central Service for the Chronically Ill of the Chicago Institute of Medicine.

INDIANA

Dr. Bennett Joins Research Program.—Dr. Ivan F. Bennett, chief of psychiatric research for the V. A. in Washington, D. C., for the last two years, has

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

joined the Lilly Laboratory for Clinical Research and will be in charge of Lilly's clinical research program in the field of mental health. His office is located in the Institute of Psychiatric Research at the Indiana University School of Medicine's department of psychiatry.

KENTUCKY

General Practice Meeting at Fort Knox.—The annual meeting of the Kentucky Academy of General Practice at Ireland Army Hospital, Fort Knox, has been scheduled for Oct. 30. Dr. David G. Miller, Morgantown, will present "Insect Bites." The program also includes the following:

X-Ray in General Practice, Lt. Col. Russell E. Graf, M. C., Chief of X-Ray Service.
Renal Disease in Children, Capt. George L. Blum, M. C., Pediatrician.
Current Therapy of Venereal Diseases, Lt. Col. Urban L. Throm II, M. C., Chief, Psychiatry and Neurology Service.
Character and Behavior Disorders, Lt. Col. Ralph E. Campbell, M. C., Chief, Psychiatry and Neurology Service.
Therapy of Angina, Lt. Col. Jules J. McNerney, Chief, Medical Service.
Recent Advances in Laboratory Procedures, Lt. Col. Edward J. Fadell, Chief, Laboratory Service.

During the afternoon a tour is planned of the Preventive maintenance display at the hospital.

MASSACHUSETTS

Medical History Meeting.—The Benjamin Waterhouse Medical History Society will meet at the Massachusetts Memorial Hospital, Boston, Oct. 20. "Medicine at Plymouth Plantation" will be given by Dr. John J. Byrne, professor of surgery, Boston University School of Medicine, director, Third (B. U.) Surgical Service and Research Laboratory, Boston City Hospital. For reservation for dinner (6 p.m.) call KE 6-8600. The newly elected society officers for 1959 are as follows: president, Dr. Lamar Soutter; vice-presidents, Mr. George Thornton and Mr. Arnold Wong; and secretary-treasurer, Dr. John J. Byrne, all of Boston. Membership in the society is open to physicians and medical students, and applications may be obtained from the secretary at 818 Harrison Avenue, Boston 18, Mass.

MICHIGAN

Testimonial to Veteran Teachers.—Two Hundred faculty members of the University of Michigan Medical School, Ann Arbor, met at a Testimonial Dinner and paid tribute to five of their colleagues whose service to the school totals 156 years. The five are Bradley M. Patten, Ph.D., retiring chairman of the department of anatomy, Dr. Cyrus C. Sturgis, chairman of the internal medicine department, and Dr. Frederick A. Coller, retired chairman of the surgery department. Elizabeth C. Crosby, Sc.D., professor of anatomy, and Dr. Ruth C. Wanstrom of the department of pathology, also were honored.

Rabies in Coyote.—The state health department has announced that rabies has been found in a coyote shot west of Newberry in the Upper Peninsula. No previous cases of rabid coyotes are listed in state health department records. Rabies had been reported in the Upper Peninsula since 1940. However, the disease has been epidemic in Canada just north of Sault Ste. Marie since 1954, and it is believed to have been brought into Michigan last winter by rabid wild animals that crossed the frozen St. Mary's River that separates Michigan from Canada in the Soo area. Chippewa County, in which Sault Ste. Marie is located, has reported several cases in animals, this year.

University Hospital Reports on Services.—The University of Michigan Medical Center, Ann Arbor, in a report on its activities during the fiscal year ending June 30, announced that hospital patients are taking more medicine, having fewer surgical operations and more babies, and are staying in the hospital a shorter length of time. Dr. Albert C. Kerlikowske, director, announced that the average length of stay of patients admitted to the University of Michigan Hospital reached a new low of 11.8 days, compared with 12.23 days the previous year, and an average of 16¼ days 10 years ago. Physical changes in the Center during the past year include the addition of a patient's chapel; a new kitchen capable of serving up to 10,000 meals daily to patients and staff; and a Poison Information Service for emergency consultation by doctors in the state; and remodeling of the Heart Station, main lobby and patient's rooms.

MISSOURI

Hospital Research Grants.—More than $133,000 in research grants has been received by investigators of the Research Institute of the Jewish Hospital of Saint Louis. Of this amount, $126,000 came from the Public Health Service's National Institutes of Health. Nearly $54,000 was awarded to Dr. Herman T. Blumenthal, director of the Institute of Experimental Pathology. Over $45,000 in NIH support was granted to Dr. Robert Goldstein, research audiologist, and Dr. Stanley R. Lang, research physiologist, was awarded $27,615 by the NIH.

NEW HAMPSHIRE

Dr. Robb Visiting Professor.—Dr. Jane Sands Robb, associate professor of pharmacology of the State University of New York Upstate Medical Center in Syracuse, has accepted position as visiting professor of pharmacology at Dartmouth Medical School, Hanover. For her studies on the anatomy and physiology of the heart and more recently on the effect of nerve stimulation and of drugs upon cardiac muscle fibers and nucleic acid derivatives, Dr. Robb has received the Bronze Medal of the Canadian and American Medical Association and first prize of the New York State Medical Association. She won the Elizabeth Blackwell Citation in 1953. Dr. Robb previously was professor of physiology of Woman's Medical College of Pennsylvania and was director of a laboratory of experimental pharmacology at the college and organized and became chief of the Cardiac Clinic at Woman's Hospital of Pennsylvania, in Philadelphia.

NEW JERSEY

Alumni Meeting in Jersey City.—The 11th annual program of the Jersey City Medical Center Alumni Association will be held Nov. 5. A clinicopathological conference will be held at 11 a. m. Dr. Carroll M. Leevy, associate professor of clinical medicine, Seton Hall College of Medicine, will moderate a symposium on infectious diseases at 2 p. m. Speaker at the banquet (7:30 p. m.) will be Dr. Chester S. Keefer, Boston, whose topic will be "What's Ahead for American Medicine."

NEW YORK

New Cases of Poliomyelitis.—The State Health Department has announced that 13 new cases of poliomyelitis, 6 of them paralytic, were reported in Upstate New York during the week ending Sept. 25. In the corresponding week in 1957, eight cases, of which four were paralytic, were reported.

From the first of the year through Sept. 25, a total of 113 cases of poliomyelitis has been reported, compared to 106 last year and an average of 1,165 for the years 1951 through 1953. Sixty-two of this year's cases were paralytic, compared to 49 last year and an average of 647 for the years 1951 through 1953.

The six paralytic cases reported for the week ending Sept. 25 occurred in persons who had not received the full series of three anti-poliomyelitis shots. So far this year, only nine of the paralytic cases have occurred in persons having the full series of three shots. Erie, Suffolk, and Westchester counties each reported two cases of paralytic poliomyelitis. The nonparalytic cases occurred in Suffolk (2), Dutchess (2), Broome, Jefferson, and Nassau counties.

New York City

Award University Medal.—The New York University Medal was presented Sept. 19 to Sir Harold Himsworth, K.C.B., secretary of the Medical Research Council of Great Britain. The medal which was conferred by NYU President Carroll V. Newsom is presented to "distinguished visitors" to the University. Sir Harold is the 12th recipient. The citation read in part ". . . Sir Harold Himsworth has distinguished himself as a medical scientist, educator and author, primarily in the field of metabolic diseases and nutritional disorders."

Establish Pollen Sampling Stations.—Ragweed pollen sampling stations went into operation recently in six New York State communities, it was announced by Dr. Herman E. Hilleboe, state health commissioner and chairman of the State Air Pollution Control Board. Until the first killing frost, the six-station network will report on airborne ragweed pollen concentrations in Islip, Johnson City, Syracuse, Albany, Pine Hills (Ulster County), and Poughkeepsie. The network is a part of the board's air pollution control program. Daily pollen counts will be made available to newspapers, radio and television stations. The counts will provide data for research and statistical purposes.

OKLAHOMA

Annual Clinical Conference in Oklahoma City.—The 28th annual fall conference of the Oklahoma City Clinical Society will be held at the Biltmore Hotel, Oklahoma City, Oct. 27-29. Guest lecturers include the following: Drs. C. Knight Aldrich, Edwin J. DeCosta, Claude N. Lambert, and John T. Reynolds, Chicago; James Barron, Detroit; Blair E. Batson, Jackson; Parker R. Beamer, Indianapolis; Louis A. Brunsting Sr., Rochester, Minn.; E. Grey Dimond, Kansas City; Harold Gifford Jr., Omaha; Isadore Meschan, Winston-Salem; Clarence T. Ray, Columbia, Mo.; Russell B. Roth, Erie, Pa.; John M. Sheldon, Ann Arbor, Mich.; and John Alexander Wall, Houston, Texas. Guest speaker at the banquet Oct. 27, will be Dr. Roth. Exhibits, luncheon discussions and a ladies program have been arranged. Registration fee is $20. For information write the Oklahoma City Clinical Society, 503 Medical Arts Building, Oklahoma City 2, Okla.

PENNSYLVANIA

Dr. Fischer Named Director of Health Service.—Dr. Carl C. Fischer, chairman, department of pediatrics, Hahnemann Medical College and Hospital, has been appointed health service director at Girard College, succeeding Dr. Edward L. Bauer, who retired Aug. 31. Dr. Fischer, who will retain his position at Hahemann but retire from 30 years of private practice, assumed his new duties at Girard College Sept. 2.

Dr. Hammon on Mission to Thailand.—Dr. William McD. Hammon, head, department of epidemiology and microbiology, University of Pittsburgh Graduate School of Public Health, left Sept. 11 for Bangkok, Thailand, where he will serve as consultant on an epidemic of an unidentified fever disease. His services were requested by the Thai government. During the last three months in the Bangkok area, an estimated 1,500 persons have been hospitalized and 300 have died of a disease principally affecting children under the age of 10. Thai health officials are said to believe the outbreak may be the same as Philippine hemorrhagic fever, a disease Dr. Hammon and his staff have been studying for two years.

WASHINGTON

Dr. Hogness Named Hospital Director.—The appointment of Dr. John R. Hogness, of Seattle, as medical director of the University Hospital has been approved by the Board of Regents. Dr. Hogness, who has been with the University of Washington School of Medicine on a half-time basis in recent years, will begin work as medical director at once on that basis, but will assume full-time duties when the hospital opens next May. Dr. Hogness will supervise teaching activities related to patient care in the hospital and will coordinate referral of patients by physicians in all parts of the state. He will also continue teaching and research activities in the department of medicine. Dr. Hogness is a former secretary-treasurer of the King County Medical Society, and is now secretary-treasurer of the Northwest Society for Clinical Research.

WEST VIRGINIA

Physicians on School Boards.—At least 15 members of the West Virginia State Medical Association have been elected members of county boards of education. Of the 15, there are 12 already serving, and 3 will take office Jan. 1, 1959. A few counties have not yet reported to the State Department of Education, so the complete list of members of county boards of education is not available. The following physicians are now serving as members of the county boards of education: Drs. Herbert M. Beddow, Charleston; Arthur B. Carr, War; Homer O. Van Tromp, French Creek; Paul L. McCuskey, Parkersburg; Guy H. Michael, Parsons; Flavius C. Chandler, Bridgeport; Edward B. Randolph, Clarksburg; Ralph M. Fisher, Weston; Clark K. Sleeth, Morgantown; James W. Stokes, Hinton; Richard F. Miller, Paden City; Clinton W. Stallard Jr., Montgomery. The following members of boards, elected at the August primary, who will take office Jan. 1 include Dr. Carl C. Tully, of South Charleston; Dr. George W. Rose, Clarksburg; and Dr. William F. Daniels, of Huntington.

GENERAL

Meeting on Psychiatry in Brooklyn.—The third annual meeting of the Eastern Psychiatric Research Association, will be held Oct. 23-25 at the Brooklyn State Hospital, Brooklyn. Dr. Nathan Beckenstein, director of the hospital, will open the meeting with an address "Various Types of EST and Their Indications". A symposium, "Building Stones for a Biologic or a Preventive Psychiatry," will include the following: Biochemical Aspects, Personality Aspects, Conditioning Aspects, and Social Psychiatric Aspects. Dr. Charles Buckman will present "Reappraisal of the Effectiveness of Various Electrostimulative Technics Including ECT" with demonstrations.

Grants for Cancer Research.—Seven contracts totalling $256,986 for research on improved methods of testing possible anticancer agents and for related work have been announced by the Public Health Service. Four contracts are for studying new testing methods. Included in this work will be methods using tissue culture, bacteria, and a number of animal tumors. These contracts are with Michigan Department of Health, Lansing, $26,867; University of Virginia, Charlottesville, $25,155; Children's Cancer Research Foundation, Inc., Boston, $70,011; and University of Miami, Miami, Fla., $49,450. The three remaining contracts are for producing mice and rats needed in chemotherapy studies and related work. The contracts will be administered by the Cancer Chemotherapy National Service Center at the National Cancer Institute, Bethesda, Md.

Fellowships for Pediatric Study.—Grants providing for postgraduate pediatric studies will be awarded again in 1959 by Wyeth Laboratories, Dr. Philip S. Barba, past-president of the American Academy of Pediatrics, has announced. Wyeth, a pharmaceutical manufacturing firm, will award 20 two-year grants, each carrying an annual stipend of $2,400. The first three years of the program will cost $195,000. Candidates may include interns, physicians who have recently completed their internship, military service, and research fellows. Recipients who must be citizens of the U. S. or Canada, may attend any hospital whose residency program is properly accredited by the Residency Review Committee of the American Board of Pediatrics. Serving with Dr. Barba on the fellowship selection committee are Dr. John A. Anderson, Minneapolis; Dr. Amos Christie, Nashville, Tenn.; Dr. Hugh A. Carithers Jr., Jacksonville, Fla.; and Dr. A. Crawford Bost, San Francisco. Application for fellowships must be submitted by Nov. 28 to a committee member. The grants will be effective on July 1, 1959. Information and applications may be obtained from Dr. Barba at the University of Pennsylvania School of Medicine.

Annual Meeting on Preventive Medicine.—The American College of Preventive Medicine will hold its annual meeting Oct. 29-30 in St. Louis, with headquarters at the Sheraton-Jefferson Hotel. The Annual Lectureship will be given Oct. 29, 8 p. m., in the Ivory Room of the hotel by Dr. Irvine H. Page, Cleveland, on "Arteriosclerosis—Its Multifaceted Nature." A business meeting will follow. The session on Oct. 30 will be held in Assembly Hall No. 2 of the Kiel Auditorium, 9:45 a. m.; speakers will present the following topics:

The Federal Government and the National Health, Dr. Aims C. McGuinness, Washington, D. C.
Programmatic Research in the Fields of Health, Dr. Kenneth M. Endicott, Bethesda, Md.
Living in a Radioactive World, Dr. Thomas L. Shipman, Los Alamos, N. M.
Physiological Problems of Space Flight, Dr. Stanley C. White, Wright-Patterson AFB, Ohio.

Currently, the officers of the College are: president, Dr. Vivian A. Van Volkenburgh, Albany; president-elect, Dr. Louis C. Kossuth, Colorado Springs; vice-presidents, Dr. Charles E. Smith, Berkeley; Dr. George K. Fair, Washington; Dr. James H. Sterner, Rochester; secretary-treasurer, Dr. John J. Wright, Chapel Hill.

Fellowships in Pediatrics.—The American Academy of Pediatrics will grant 18 or more fellowships to pediatric residents for the fiscal year 1959-1960 and covering a period of six months to one year. These fellowships have been created to enable young physicians, who are legal residents of the United States or Canada and who are in financial need, to complete their pediatric training. The fellowships which carry a stipend of $500 to $1,000, have been made possible by a grant to the Academy from Mead Johnson & Company. They will be granted as of July 1, 1959.

Requirements are: (1) a letter from the chief of service indicating that the proposed individual has completed or will have completed by July 1, 1959, one year of pediatric training credited by the American Board of Pediatrics; that the resident has performed his work ably; and that there is real need for financial assistance; (2) a letter from the resident who is requesting the fellowship stating that he intends to enter pediatric private practice at the conclusion of his residency training. Up to 25% of the fellowships may be awarded to those who desire a third or fourth year of residency before entering private practice. Those interested in applying may correspond with the American Academy of Pediatrics, 1801 Hinman Ave., Evanston, Ill.

Annual Heart Association Meeting in San Francisco.—Ninety original scientific papers will be presented at the American Heart Association's 31st annual scientific sessions in San Francisco's Civic Center, Oct. 24-26. In addition, there will be about 30 papers read by invited speakers. A scientific session for clinicians Oct. 24 under sponsorship of the Council on Clinical Cardiology will include symposiums on "Congenital Heart Disease," "Treatment of Intravascular Clotting," and "Peripheral Arterial Insufficiency." A panel discussion, "What's New in Arrhythmias," will be held. These sessions have been classified by the American Academy of General Practice as acceptable for credit. A joint session of the American Society for the Study of Arteriosclerosis and the American Heart Association is planned for Oct. 14. The Lewis A. Conner Memorial Lecture will be given at a general session on Applied Cardiovascular Research by Dr. John H. Gibbon Jr., Philadelphia, on "Maintenance of Cardio-Respiratory Functions by Extracorporeal Circulation," and the George E. Brown Memorial Lecture by Dr. Lewis Thomas, New York City, on the "Role of Hypersensitivity in Cardiovascular Disease." On Oct. 25 panels on Arteriosclerosis will be presented jointly with the A. S. S. A. A special program, "Rewards of Research," followed by a session on Rheumatic Fever Secondary Prevention Programs are planned for the afternoon of Oct. 26, with the association's annual dinner to be held at the Fairmont Hotel that evening. A medical film program and a section of scientific and industrial exhibits are arranged. For information write the American Heart Association, 44 E. 23rd St., New York 10.

Meeting of Surgeons in Hot Springs, Va.—The United States Section, International College of Surgeons, will hold its Mid-Atlantic regional meeting at the Homestead, Hot Springs, Va., Nov. 17-18. Two panel discussions are planned: "Head, Neck, Shoulder, Arm Syndrome Following Cervical Injury," moderated by Dr. Khalil G. Wakim, Rochester, Minn., and "Management of Acute Surgical Emergencies Due to Trauma," moderated by Dr. James W. Watts, Washington, D. C. The scientific program includes the following papers:

Manifold Value of Endoscopic Photography in Surgery, Dr. Lowrain E. McCrea, Philadelphia.
Surgical Management of the Horseshoe Kidney, Dr. Theodore R. Fetter, Philadelphia.
New Details in Corrective Surgery for External Nasal Deformities, Dr. Albert P. Seltzer, Philadelphia.
Carcinoma of the Right Colon, Dr. Russell V. Buxton, Newport News, Va.
Application of Plastic Surgery Principles in Orthopedic Surgery, Dr. Roy R. Raub, Bluefield, Va.
Present Status of Adenotonsillectomy, Dr. Francis H. McGovern, Danville, Va.
Pathological Physiology of Diaphragmatic Esophageal Haital Hernia, Dr. Samuel Randolph Penn, Waynesboro, Va.
Parathyroid Diseases, Dr. Henry F. Warden, Bluefield, Va.
Care and Rehabilitation in Major Industries by a Modern Steel Industry Medical Department, Dr. James L. Thompson, Weirton, W. Va.
Use of Roux-Y-Anastomosis in Pancreatic Disease, Dr. Alva H. Letton, Atlanta.

A movie, "Simplified Techniques in Cataract Surgery," will be given by Dr. Elbyrne G. Gill, Roanoke, Va. For information write to Dr. Gill at 711 Jefferson St. South, Roanoke 13, Va.

Fellowships for Study in Respiratory Diseases.—The medical section of the National Tuberculosis Association, the American Trudeau Society, provides a limited number of fellowships to promote the training of clinicians, medical teachers, and scientific investigators in tuberculosis and respiratory diseases. Awards are open to citizens of the U. S. for work in this country. Candidates holding the degrees of M.D., Ph.D., or Sc.D. are eligible for awards making possible continuation of graduate study in the field of respiratory diseases in an approved hospital or medical center. Residency in an approved hospital under such a fellowship will be credited by the American Board of Internal Medicine toward certification in internal medicine and pulmonary diseases. Predoctoral fellowships are also offered to graduate students who hold a bachelor's degree and are working on a research project for an advanced degree other than an M.D. Each applicant must have the approval of the head of the department under whom he expects to work. Awards are determined by individual circumstances and are paid directly to the fellow on a quarterly basis. Fellowships, granted for one year (not more than two renewals will be considered), must be applied for by December 1. Appointments may begin on any date.

A few fellowships at a higher level of training and award are offered to specially qualified candidates with an M.D. degree who have been assured of a continued teaching or research appointment upon completion of training. Trudeau Fellowships are awarded for one year but may be renewed up to a total period of four years. Information may be obtained upon request from the Director of Medical Education, American Trudeau Society, c/o The Henry Phipps Institute, Seventh and Lombard Streets, Philadelphia 47.

CANADA

Annual Meeting on Fertility.—The fifth annual meeting of the Canadian Society for the Study of Fertility will be held Oct. 31-Nov. 1 in London, Ontario. Speakers from the United States will include Dr. Lawson Wilkins, Baltimore, and John Buettner-Janusch, M.A., New Haven, who will present "Masculinization of the Female Foetus Following the Administration of Progestons to the Mother" and "Role of the A B A (H) Blood Group System in Human Sterility and Habitual Abortion," respectively. Other topics and speakers are:

Psychogenic Factors in Infertility, Drs. Robert A. Cleghorn and Carlo G. Bos, Montreal.
Occult Vaginal Bleeding, Dr. Abraham Hurtig, Ottawa.
Endocrine Disturbances Caused by Pituitary and Hypothalmic Tumours, Dr. John C. Beck, Montreal.
Role of Vaginal Cytology in Endocrine Disturbances, Dr. Jack H. Walters, London.
Considerations on Hysterosalpingography by Cinematography and Utero-Tubal Kymographic Insufflation, Dr. Samuel Letendre, Monreal.

A discussion on new approaches to the problem of infertility is planned. For information write Dr. Jean F. Campbell, Secretary-Treasurer, Canadian Society for the Study of Fertility, 238 Queen's Ave., London, Ontario, Canada.

CORRECTION

Spinal-Tap Headache.—In the article on "Technique to Avoid Spinal-Tap Headache" in The Journal, Sept. 20, page 262, in the second paragraph, line 7, under "Method," the word "decrease" should have read "increase."

EXAMINATIONS AND LICENSURE

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates, Inc.: The American medical qualification examination to be given henceforth twice a year for foreign medical graduates. Medical Schools in the United States and Foreign Countries, Sept. 23. Final date for filing application was June 23. Dates for the 1959 examinations have been set for Feb. 17 and Sept. 22. Executive Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Illinois.

BOARDS OF MEDICAL EXAMINERS

Alaska:[*] On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.
California: *Written Examination.* Sacramento, Oct. 20-23. *Oral Examination.* San Francisco, November 15. *Oral and Clinical Examination for Foreign Medical School Graduates.* San Francisco, June 15; Los Angeles, August 17; San Francisco, November 16. Sec., Dr. Louis E. Jones, 1020 N Street, Sacramento.
Colorado: *Endorsement.* Denver, Oct. 14. *Written.* Denver, Dec. 9-10. Exec. Sec., Mrs. Beulah H. Hudgens, 715 Republic Bldg., Denver 2.
Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.
Maine: *Examination and Reciprocity.* Portland, Nov. 12-14. Sec., Dr. Adam P. Leighton, 142 High St., Portland.
Montana: *Examination and Reciprocity.* Helena, Oct. 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.
New Mexico:[*] *Examination and Reciprocity.* Santa Fe, Nov. 17-18. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.
Ohio: *Examination.* Columbus, Dec. 16-18. *Endorsement.* Columbus, August 18; October 6 and Dec. 16-18. Sec., Dr. H. M. Platter, Wyandotte Bldg., Columbus 15.
South Carolina: *Endorsement.* Columbia, Dec. 9. Sec., Dr. H. E. Jervey, Jr., Blanding Bldg., Columbia.
Texas:[*] *Examination and Reciprocity.* Fort Worth, Dec. 4-6. Sec., Dr. M. H. Crabb, 1714 Medical Arts Building, Fort Worth 2.
Wisconsin: *Reciprocity.* Madison, Oct. 16-18. Sec., Dr. Wm. H. Barber, 621 Ransom St., Ripon.
Wyoming: *Examination and Reciprocity.* Cheyenne, Oct. 6. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination.* Juneau, Nov. 4. Sec., Dr. R. Harrison Leer, Room 204, Alaska Office Bldg., Juneau.
Arkansas: *Examination.* Little Rock, Oct. 6-7. Sec., Dr. S. C. Dellinger, Zoology Department, University of Arkansas, Fayetteville.
District of Columbia: *Reciprocity. Examination.* Washington, Nov. 13-14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N. W., Washington 6.
Kansas: *Examination and Reciprocity.* Kansas City, Nov. 24-25. Sec., Dr. L. C. Heckert, Pittsburg.
Michigan: *Examination.* Ann Arbor and Detroit, Oct. 10-11. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., W. Michigan Ave., Lansing 15.
Texas: *Examination.* Oct. 13-14. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.
Wisconsin: *Examination.* Milwaukee, Dec. 6. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

[*] Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE

Consultants and Command Surgeons Conference.—The surgeon general convened a three-day National Consultants and Command Surgeons Conference at Andrews Air Force Base Hospital, Washington, D. C., on Sept. 3, to provide an interchange of the latest military and civilian medical thinking and techniques.

Guest speakers were Dr. William N. Hubbard Jr., associate dean of New York University College of Medicine, who spoke on medical education, and Dr. Lawrence E. Lamb of the U. S. A. F. School of Aviation Medicine, Randolph Air Force Base, Texas, who presented the problems of syncope.

The consultants who made presentations on their respective specialties were Dr. Conrad G. Collins, Tulane University School of Medicine, New Orleans, obstetrics and gynecology; Dr. Charles E. Smith, University of California, Berkeley, preventive medicine; Dr. Clarence C. Pearson, Seattle, internal medicine; Dr. Louis J. West, University of Oklahoma Medical Center, psychiatry; Dr. Edgar J. Poth, University of Texas Medical Branch, Galveston, Surgery; Dr. Sidney S. Chipman, University of North Carolina, Chapel Hill, pediatrics; Kenneth A. Easlick, D.D.S., University of Michigan, dental care; Dr. Clair M. Kos, State University of Iowa, Iowa City, otolaryngology.

NAVY

Establish Course in Nuclear Nursing.—A new phase in the education of military nurses began at the Naval Medical School, Bethesda, Md., on Sept. 2, when the first course in the nuclear field ever to be offered nurses in the United States got under way. The course was planned because (1) in medicine, the field of radioisotopes is rapidly expanding and "nursing participation" is required and (2) in the fleet, the advancement in the Navy's nuclear power program demands "nursing readiness."

The four-month course which includes instruction in the principles underlying radioisotope therapy and procedures for the care of mass casualties is under the direction of Capt. E. Richard King, M.C., director of the medical school's department of nuclear medicine.

Physicians from Twelve Nations Attend Training Program.—Twenty-two military medical officers representing the armed forces of 12 nations convened at the Naval Medical School, Bethesda, Md., Sept. 2, under a 10-week training program sponsored by the Chief of Naval Operations, Admiral Arleigh Burke, U. S. N. Senior officers are studying naval hospital management; junior officers, preventive medicine. Rear Admiral Bartholomew W. Hogan, the surgeon general, welcomed the student officers.

The course in hospital management consists of a review of the theory and principles of hospital management and their special application to the operation of military hospitals. The preventive medicine course consists of a review of modern preventive medicine as it applies to troops afloat and ashore. Field trips are planned to medical, military, industrial, and cultural activities east of the Mississippi. Outstanding speakers from civilian and military activities comprise the teaching staff.

PUBLIC HEALTH SERVICE

Report on Radioactivity in Milk.—The Public Health Service reported Sept. 19 that tests for radioactivity in milk from nine locations in the United States showed amounts well within the permissible levels recommended by the National Committee on Radiation Protection and Measurement. The report covers the months of May, June, and July and brings up to date the findings of the study initiated by the Public Health Service in the spring of 1957.

Composite milk samples were analyzed by the service to measure amounts of specific radioisotopes, including strontium-90. It takes at least six weeks to complete the laboratory analyses of the samples and tabulate the results.

The maximum permissible levels recommended by the National Committee on Radiation Protection and Measurement are specifically for water but have been generally accepted in practice as being applicable also to milk. These limits represent concentrations which are currently considered safe over a lifetime and which may occasionally be exceeded for short periods of time.

Immunization Information for International Travel.—A new edition of the booklet "Immunization Information for International Travel" has been issued by the Public Health Service. It is designed primarily for travelers going abroad and for health departments and physicians. It gives current details on immunization requirements for persons entering the United States, including Americans returning from abroad. It lists requirements for immunization in 200 other countries. Information on bringing pets into the United States from other countries is included.

The booklet is for sale by the Superintendent of Documents, Government Printing Office, Washington, D. C., for 30 cents.

DEATHS

Anderson, James Harlan, Aurora, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; served on the staffs of the Copley and St. Joseph's hospitals; died Aug. 7, aged 73, of cerebral hemorrhage.

Anthony, Walter E. Ⓜ Ottumwa, Iowa; Jefferson Medical College of Philadelphia, 1912; veteran of World War I; medical examiner for the local draft board during World War II; on the staffs of the Ottumwa and St. Joseph Mercy hospitals; died Aug. 22, aged 69, of coronary thrombosis.

Banks, William Henry, San Francisco; Cooper Medical College, San Francisco, 1904; an associate member of the American Medical Association; died in Decoto Aug. 20, aged 84.

Barber, Thomas Maxfield Ⓜ Charleston, W. Va.; Medical College of Virginia, Richmond, 1917; member of the American Academy of General Practice and past-president of the West Virginia Chapter; past-president and treasurer of the Kanawha County Medical Society; for 31 consecutive years treasurer of the West Virginia State Medical Association and last August was reelected for his 32nd consecutive term; veteran of World War I and was awarded the Distinguished Service Cross; vice-president of the Children's Home Society of West Virginia; on the staff of Charleston General Hospital; died Aug. 26, aged 64, of coronary occlusion.

Barnes, Bruce Smith Ⓜ Lancaster, Texas; Indiana University School of Medicine, Indianapolis, 1944; interned at the Indianapolis City Hospital; served a residency at the Methodist Hospital in Dallas; veteran of World War II; associated with Chester Clinic and Hospital; died in Galveston Aug. 17, aged 37, of coronary occlusion.

Barnett, Jacob, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1897; an associate member of the American Medical Association; fellow of the American College of Surgeons; on the staffs of the Charity Hospital and the Touro Infirmary, where he died Aug. 22, aged 82, of arteriosclerotic heart disease and chronic glomerular nephritis.

Barrett, Michael Francis Ⓜ Brockton, Mass.; born in Hingham in 1875; Harvard Medical School, Boston, 1901; fellow of the American College of Surgeons; past-president of the Brockton Medical Society; served the Brockton Hospital as president of the medical staff, a member of the executive committee of the medical staff, on the executive committee of the board of trustees, and as a trustee at the hospital from 1939; continued to be a member of the special consulting staff in surgery at the hospital until his death; became a trustee at Phaneuf Hospital in 1938 and served as chief of surgery until his retirement in 1957; last year at a dinner given in his honor, the doctors, nurses, and administrative personnel of the hospital presented him with an oil painting of himself; died in the Brockton Hospital Aug. 13, aged 82, of spontaneous subdural hematoma.

Barrymore, Eugene Ⓜ Bowling Green, Mo.; St. Louis University School of Medicine, 1907; died in Veterans Administration Hospital, St. Louis, July 12, aged 79, of acute myocardial infarction.

Beckwith, Henry Witter, Lynn, Mass.; Dartmouth Medical School, Hanover, N. H., 1902; died in Nahant Aug. 6, aged 89, of hypostatic pneumonia.

Beede, Ralph Worthing Ⓜ Youngstown, Ohio; Ohio State University College of Medicine, Columbus, 1937; member of the American Academy of General Practice; on the staff of the South Side Unit of the Youngstown Hospital; died Aug. 19, aged 63, of a self-inflicted bullet wound in the head.

Bell, James Edgar, Trafford, Ala.; University of Nashville (Tenn.) Medical Department, 1897; member of the Medical Association of the State of Alabama; died July 24, aged 84, of arteriosclerotic heart disease.

Binter, Paul Albert Ⓜ Wichita, Kan.; University of Kansas School of Medicine, Kansas City, 1942; specialist certified by the American Board of Internal Medicine; veteran of World War II; associated with St. Francis, St. Joseph, Wesley, and Veterans Administration hospitals; died Aug. 26, aged 43, of coronary occlusion.

Blake, Wendell Phillipps Ⓜ Captain, U. S. Navy, retired, Washington, D. C.; College of Physicians and Surgeons, Los Angeles, 1913; entered the U. S. Navy in May 1920; retired Jan. 1, 1946; service member of the American Medical Association; died June 25, aged 69, of coronary occlusion.

Bosenbury, Charles Searles Ⓜ Coral Gables, Fla.; Rush Medical College, Chicago, 1903; member of the Indiana State Medical Association; for many years practiced in South Bend, Ind., where he was city health officer; veteran of World War I; died in the Doctor's Hospital Aug. 22, aged 81.

Ⓜ Indicates Member of the American Medical Association.

Bradford, William Herbert Ⓜ Portland, Maine; Medical School of Maine, Portland, 1891; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served on the faculty of his alma mater; past-president of the Cumberland County Medical Society; a founder and past-president of the New England Surgical Society; on the medical advisory board of Cumberland County during World War I; member of the *consulting staff, Webber Hospital, Biddeford,* Maine Eye and Ear Infirmary, Maine General Hospital, Bath (Maine) Memorial Hospital, and the Children's Hospital; died Aug. 21, aged 92, of bronchopneumonia and arteriosclerotic heart disease.

Brody, Arnold Warren, Chicago; Chicago Medical School, 1955; certified by the National Board of Medical Examiners; resident at the Cook County Hospital; died Aug. 19, aged 29, of chronic glomerulonephritis.

Brumfiel, Daniel Milton Ⓜ Saranac Lake, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1924; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Trudeau Society; past-president of the Franklin County Medical Society; vice-president of the Saranac Lake Tuberculosis Society; associated with Lake Placid (N. Y.) Memorial Hospital and the Saranac Lake General Hospital; died Aug. 20, aged 68, of cancer.

Bruno, John Robert Ⓜ Conshohocken, Pa.; Jefferson Medical College of Philadelphia, 1941; formerly an officer in the U. S. Navy; veteran of World War II; on the courtesy staff of the Sacred Heart Hospital, Norristown, where he died Aug. 26, aged 43, of hemorrhagic pancreatitis.

Busman, George J. Ⓜ Pittsburgh; University of Michigan Medical School, Ann Arbor, 1918; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; served on the faculty of the University of Pittsburgh School of Medicine; entered the Mayo Foundation in Rochester, Minn., as a fellow in dermatology in 1918 and left in 1922; on the staffs of the Roselia Foundling Asylum and Maternity Hospital and the Mercy Hospital, where he died Aug. 17, aged 66, of aneurysm of the aorta.

Clancy, Frank Jeffery Ⓜ Seattle; born in Everett, Wash., July 12, 1892; University of Oregon Medical School, Portland, 1918; in 1936-1937 director of the Bureau of Investigation of the American Medical Association; past-president of the Washington State Urological Association; member of the American Urological Association; fellow of the American College of Surgeons; served as chairman of the Public Health League of Washington; associated with Doctors and Columbus hospitals; veteran of World War I; author of "Doctor, Come Quickly"; died Aug. 8, aged 66, of hepatitis and diabetes mellitus.

Corry, Lawrence Fitzgerald Ⓜ Menasha, Wis.; St. Louis University School of Medicine, 1926; on the staff of the St. Elizabeth Hospital, Appleton, where he died Aug. 2, aged 55, of hypertensive cardiovascular disease and uremia.

Durham, Silas Lucius Ⓜ Dearborn, Mo.; Tulane University School of Medicine, New Orleans, 1913; president of the Platte County Medical Society; on the staff of the Missouri Methodist Hospital in St. Joseph; died Aug. 14, aged 74.

Faltin, Ladislaus Ⓜ South Bend, Ind.; Universita Karlova Fakulta Lekarska, Praha, Czechoslovakia, 1921; specialist certified by the American Board of Internal Medicine; served on the staff of St. Joseph Hospital; died in St. Francis Hospital, Miami Beach, Fla., Aug. 17, aged 62, of cerebral hemorrhage.

Farrell, Charles Vincent Ⓜ Bellingham, Wash.; St. Louis University School of Medicine, 1924; member of the American Academy of General Practice; died in St. Joseph's Hospital Aug. 14, aged 64, of recurrent coronary thrombosis with myocardial infarction.

Fearrington, James Cornelius Pass Ⓜ Winston-Salem, N. C.; Rush Medical College, Chicago, 1930; associate professor of clinical internal medicine at Bowman Gray School of Medicine of Wake Forest College; on the staffs of the City Memorial and North Carolina Baptist hospitals; died Aug. 10, aged 59.

Feltenstein, David William, St. Joseph, Mo.; Northwestern Medical College, St. Joseph, 1887; College of Physicians and Surgeons of Chicago, 1888; died in Kansas City June 27, aged 88, of myocardial infarction.

French, Oscar William, O'Neill, Neb.; University of Nebraska College of Medicine, 1920; member of the American Academy of General Practice; on the staff of St. Anthony's Hospital; died in the Saunders County Hospital, Wahoo, Aug. 3, aged 66, of cardiovascular renal disease and cerebral thrombosis.

Gray, George Morris Ⓜ Kansas City, Kan.; born in Waukegan, Ill., March 4, 1856; Kansas City (Mo.) Medical College, 1879; Bellevue Hospital Medical College, New York City, 1880; clinical professor emeritus of surgery at University of Kansas School of Medicine; past-president of the Kansas Medical Society, of which he was treasurer for many years;

past-president of the Wyandotte County Medical Society and the Kansas City Academy of Medicine; member of the Western Surgical Association; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association, 1913, 1922 and 1923; served as mayor during a period in 1906-1907; from Dec. 10, 1917, to Jan. 4, 1919, when he was a member of the medical corps of the U. S. Army, served as medical military aide to the governor; became a member of the surgical staff of St. Margaret's Hospital, when it opened and served as chief of the surgical staff for many years; served as county physician and county coroner; honorary chairman of the board of the Riverview State Bank, of which he was a director for many years; honorary member of the board of the Security National Bank; chairman of the board of the Victory State Bank; died in St. Margaret's Hospital Aug. 12, aged 102, of arteriosclerotic cardiovascular renal disease.

Johnston, Edward Estill, Elizabethtown, Ky.; Indiana University School of Medicine, Indianapolis, 1915; member of the Kentucky State Medical Association; veteran of World Wars I and II; died Aug. 8, aged 66.

Katz, Maxwell Clarence, Kings Point, N. Y.; Long Island College Hospital, Brooklyn, 1912; died Aug. 16, aged 65, of cardiac decompensation and coronary occlusion.

Kun, Bertram Bela Ⓜ Jersey City, N. J.; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1928; member of the American College of Chest Physicians; veteran of World War II; associated with Jersey City Medical Center, Christ and Fairmont hospitals; died Aug. 7, aged 56, of coronary occlusion.

McGhee, Saylor John Ⓜ Lock Haven, Pa.; Jefferson Medical College of Philadelphia, 1898; past-president of the Clinton County Medical Society; president of the Lock Haven Joint School Board; a director of the Lock Haven Trust Company Bank; on the staff of the Lock Haven Hospital, where he died Aug. 9, aged 86.

Mayer, Willard D. Ⓜ Detroit; Jefferson Medical College of Philadelphia, 1912; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served on the faculty of Wayne University College of Medicine; veteran of World War I; on the staff of the Harper Hospital; consulting physician, City of Detroit Receiving Hospital; died Aug. 8, aged 68, of heart disease.

Meehan, Patrick Joseph Ⓜ Lowell, Mass.; Tufts College Medical School, Boston, 1904; veteran of World War I; served as trustee of the Tewksbury (Mass.) State Hospital, where he was assistant superintendent; died in the Veterans Administration Hospital, Boston, Aug. 4, aged 79, of bronchopneumonia, pulmonary edema, chronic pyelonephritis, fracture of the left hip, and diabetes mellitus.

Menger, Louis Charles Ⓜ Kew Gardens, N. Y.; Long Island College Hospital, Brooklyn, 1910; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; on the staff of the Brooklyn Eye and Ear Hospital; died in the New York Medical School and Hospital, New York City, Aug. 19, aged 70.

Mertz, Albert Adolph Ⓜ Decatur, Ill.; University of Michigan Medical School, Ann Arbor, 1909; veteran of World War I; served as secretary of the Macon County Medical Society; died in the Decatur and Macon County Hospital Aug. 7, aged 76.

Mockett, Percy Charles, Kimball, Neb.; Denver College of Medicine, 1901; died in the Emory John Brady Hospital, Colorado Springs, Colo., May 26, aged 84, of arteriosclerotic heart disease.

Mundhenk, Herbert Conner, Dayton, Ohio; Jefferson Medical College of Philadelphia, 1902; died in the Good Samaritan Hospital Aug. 8, aged 80, of coronary thrombosis.

Neilson, Charles Hugh Ⓜ St. Louis; born in 1871; Rush Medical College, Chicago, 1905; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; professor of internal medicine at St. Louis University School of Medicine, where he was for many years associate dean; past-president of St. Louis Medical Society; served on the staffs of St. Louis City Hospital and St. Mary's Group of Hospitals; formerly chief of staff, Alexian Brothers Hospital; on the staff of St. John's Hospital, where he served as chief, department of internal medicine, and where he died Aug. 12, aged 87, of cancer.

Perkins, Orman Clarence Ⓜ Brooklyn; born in Newbourg, Maine, April 23, 1892; Long Island College Hospital, Brooklyn, 1921; formerly on the faculty of his alma mater; veteran of World Wars I and II; fellow of the American College of Physicians; member of the Association for Research in Nervous and Mental Diseases; served on the staffs of the Creedmore State Hospital in Queens Village, Kings County, Long Island College, Bushwick, Brooklyn, Caledonian, Brooklyn State, Kingston Avenue, and Swedish hospitals and Norwegian Lutheran Deaconesses' Home and Hospital; consulting neurologist, Central Islip (N. Y.) State Hospital, Rockaway Beach (N. Y.) Hospital, Southside Hospital, Bayshore, Victory Memorial, Bethany Deaconess, Evangelical Deaconess, Methodist, and Veterans Administration hospitals; died in Crawford Notch, N. H., Aug. 18, aged 66.

Rockwell, John Arnold Ⓜ Cambridge, Mass.; Boston University School of Medicine, 1899; served on the faculty of his alma mater; for many years associated with the Massachusetts Memorial Hospital, Boston, Mount Auburn Hospital in Cambridge, and the Hahnemann Hospital in Boston, where he died July 23, aged 86, of cancer.

Sartor, Pierre Ⓜ Titonka, Iowa; Bennett College of Medicine and Surgery, Chicago, 1896; past-president and secretary of the Kossuth County Medical Society; for many years health officer of Titonka, served on the town council, and was a member of the Chamber of Commerce; an honorary member of St. Ann Hospital staff in Algona; for 34 years physician for the Rock Island Railroad; died in Algona Aug. 5, aged 86, of cerebral thrombosis and bronchopneumonia.

Shahan, William Ewing Ⓜ St. Louis; born in 1877; Washington University School of Medicine, St. Louis, 1904; professor emeritus of ophthalmology at his alma mater; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, and the Association for Research in Ophthalmology; fellow of the American College of Surgeons; on the staffs of St. Luke's, Barnard Free Skin and Cancer, Barnes, St. Louis Children's, and St. Louis Maternity hospitals; died in Central Lake, Mich., Aug. 11, aged 81, of heart disease.

Shimer, Harry A. Ⓜ Bedford, Pa.; University of Maryland School of Medicine, Baltimore, 1910; vice-president of the school board and the First National Bank; on the staff of the Bedford County Memorial Hospital; died in Altoona (Pa.) Hospital Aug. 8, aged 73, of uremia.

Talbott, Edward Melville Ⓜ Colonel, U. S. Army, retired, San Francisco; Georgetown University School of Medicine, Washington, D. C., 1901; service member of the American Medical Association; in the Army until 1922, serving in Cuba, Mexico, the Philippines and in Europe in World War I; died in the Letterman Army Hospital Aug. 16, aged 80, of myocardial infarction and coronary thrombosis.

Tannhauser, Siegfried Ⓜ Buffalo; Albert-Ludwigs-Universitat Medizinische Fakultat, Freiburg, Baden, Germany, 1922; assistant professor of pathology at the University of Buffalo School of Medicine; specialist certified by the American Board of Pathology; fellow of the College of American Pathologists; member of the American Association of Pathologists and Bacteriologists; past-president of the Buffalo Pathological Society; since 1943 pathologist at the Deaconess Hospital; formerly pathologist at the Desert Sanatorium, Tucson, Ariz.; died Aug. 12, aged 61, of coronary thrombosis.

Vandemark, Walter Elbert Ⓜ Sioux Falls, S. D.; Harvard Medical School, Boston, 1942; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; certified by the National Board of Medical Examiners; at one time on the faculty of the University of South Dakota School of Medical Sciences, Vermillion; on the staffs of the Sioux Valley and McKennan hospitals; died Aug. 8, aged 43, of cerebral hemorrhage resulting from a fall.

Vaux, Norris Wistar, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1905; served as secretary of health, Pennsylvania Department of Health; formerly on the faculty of Jefferson Medical College; past-president of the American Gynecological Society; veteran of World War I; at one time on the staff of the Pennsylvania Hospital; specialist certified by the American Board of Obstetrics and Gynecology; died in Ventnor, N. J., Aug. 19, aged 76.

Vehrs, George Rudolph, Eugene Ore.; Jefferson Medical College of Philadelphia, 1916; died Aug. 2, aged 68, of pneumonia and Parkinson's disease.

Weinberger, William Ⓜ New York City; Medizinische Fakultat der Universitat, Vienna, Austria, 1894; associated with the Morrisania Hospital; died in the Lebanon Hospital Aug. 15, aged 88, of leukemia.

Weitz, Franklin Mathias Ⓜ Buffalo; University of Buffalo School of Medicine, 1933; served as school doctor for the board of education; member and past-president of the staff of the Mercy Hospital; died in Angola, N. Y., Aug. 6, aged 49.

Wilcox, Ernest Hatch Ⓜ Pleasantville, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1923; fellow of the American College of Surgeons; on the staff of the Northern Westchester Hospital in Mount Kisco and Grasslands Hospital in Valhalla; died in the Moses Ludington Hospital, Ticonderoga, Aug. 13, aged 58.

Wittenberg, Carlton Emil Ⓜ Woodstock, Ill.; University of Illinois College of Medicine, Chicago, 1935; veteran of World War II; associated with the Brokaw Hospital in Bloomington and the Memorial Hospital, where he died Aug. 21, aged 51, of coronary occlusion.

Witter, Calvin Bassler, Agoura, Calif.; Albany (N. Y.) Medical College, 1909; an associate member of the American Medical Association; died Aug. 9, aged 76.

Wright, John Francis Ⓜ Toledo, Ohio; University of Wooster Medical Department, Cleveland, 1903; veteran of World War I; associated with St. Vincent's Hospital, where he died Aug. 12, aged 78, of arteriosclerosis.

BELGIUM

Retinal Detachment.—The method of pyrometric diathermocoagulation developed by L. Coppez in 1932 is still used in the ophthalmological clinic at Brussels University. From 1949 to 1954, Coppez and Szucs operated on 243 eyes with retinal detachment; 54.8% recovered completely, 22.4% obtained anatomic cures, and in 22.8% the operation was a failure. About the same number of multiple operations were performed on the various refractive groups, with a slight predominance in myopic eyes. The percentage of cures reached its maximum when the detachment was less than one month old and gradually decreased up to six months; then the percentage increased slightly, because such patients were operated on only if some chance of success was apparent. The percentage of complete cures varied only slightly up to the age of 60 years and fell abruptly after this age. The high percentage of failures observed in young patients was attributed to a severe associated trauma.

Detachment occurred earlier in patients with myopia than in those with emmetropia, and the stronger the myopia the earlier it occurred. Fewer cures were observed in patients with slight myopia and especially in those with emmetropia, which is not surprising, for most of the patients with severe trauma belong to this group. The degree of refractive error had little influence on the results of operation, but the extent of the detachment played a preponderant role in the success of the operation; the greater the detachment the fewer the cures. The predominance of the lesions in the superior temporal quadrant was apparent in patients with myopia of over 6 diopters and in hypermetropic eyes at a lesser degree.

On the whole there was no difference between mild or severe degrees of myopia as regards the distribution of tears. In classifying the tears according to their character (punched out, linear, or horseshoe-shaped) the distribution of tears was proportional in the different refractive groups, except for the relatively high percentage of punched-out tears in the myopic eye. The predominance of tears in the superior temporal quadrant in the myopic eye might be due to the action of the oblique muscles and might be favored by an insufficient irrigation by the temporal artery or by the degenerative changes of the deep membranes of the eye in myopic patients. There was, however, also a predominance of the same kind in hypermetropic patients. This appeared to be due to a vascular arrangement which is favorable to the nutritional disturbances of the retina. Peripheral detachment appeared to diminish the chances of success. Fewer cures were observed in detachments involving the macula. Bilateral detachments were cured in a high percentage of patients. Trauma diminished the percentage of cures. Hypotension existing before operation was an aggravating factor. Chorioretinitis did not seem to diminish the chances of success.

DENMARK

Penicillin-Resistant Staphylococci.—At a meeting of the Jydsk Medical Society (*Nordisk medicin*, July 31, 1958) one speaker reported experiments with 110 members of a hospital staff whose noses had been treated with an ointment containing an antibiotic intended to render them no longer carriers of penicillin-resistant staphylococci. In addition to the encouraging results of these experiments, there was the benefit accruing to systematic coaching of the staff in the prevention of hospital cross-infections. Here much could be done to correct the laxity of hospital hygiene prompted by the early successes of penicillin when resistant organisms were unknown. The responsibility of hospital authorities for the hospital infections of patients was discussed by another speaker who cited a test case, that of a 27-year-old diabetic woman. A few days after her admission she incurred an infection with type 80 staphylococcic. Multiple abscesses formed and caused the loss of one eye and osteomyelitis of both tibias. Her appeal to have her hospital charges refunded was rejected in principle on the ground that the hospital must in such a case first be convicted of negligence.

Asthma in Children.—In 1944, Dr. W. Flensborg undertook a follow-up study of 298 children who had been treated for asthma 5 to 18 years earlier. He found that 120 had been free from attacks of asthma for a year or longer, but among them were 8 who coughed, 5 who expectorated, and 53 who were short of breath. In spite of their freedom from actual attacks of asthma, many of these children had become susceptible to emphysema and chronic bronchitis. Five had died of status asthmaticus and 10 of some other cause. The further fate of the same asthmatics was investigated by Dr. E. Ryssing

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

(*Ugeskrift for læger,* Aug. 7, 1958), who between May and September, 1957, sent a questionnaire to 283 survivors, 272 of whom replied. Of the 120 who had been free from attacks in 1944, only 58 had remained so. Evidently the prognosis was best for those asthmatics whose disease had begun early in childhood, had been of short duration, and had disappeared at about the age of 15. The deaths from asthma had risen to nine, and there was also an additional death from chronic bronchitis. As only about 30% of all the children had become symptom-free on growing up, Ryssing urged closer supervision of such patients, with early examination and specific treatment.

Therapeutic Abortions.—In Denmark the physician who undertakes a therapeutic abortion must send the Department of Public Health a report on a form setting forth the method used for inducing abortion and any complication that occurs. An opportunity is thus afforded for comparing different methods. Berthelsen and Ostergaard (*Ugeskrift for læger,* July 31, 1958) analyzed the material thus provided in the five-year period 1953-1957. The 23,666 abortions in this period resulted in 16 deaths and 697 complications. The case fatality rate was 0.13% for the abdominal approach and 0.05% for the vaginal approach. The complication rate for six different methods ranged from 2 to 4.5%. The cremor saponis method, the most widely used since 1957, emerged with credit from this comparison, but the risks of therapeutic abortion were found to be of the same degree as those of delivery at full-term.

Greenland's Invalids.—In the fall of 1956 a survey of Greenland's invalids was made. Questionnaires were sent to all the district medical officers so that 80% of the population was covered. A report on this survey by Dr. P. V. Smith (*Ugeskrift for læger,* Aug. 14, 1958) indicated that much of the invalidism noted was preventable. The list of the five most important causes involving 60% of all the persons registered as invalids was led by poliomyelitis. As the whole of Greenland's population was vaccinated against this disease in 1955 and 1956, the invalidism it inflects should be much reduced in the future. Second on the list were the mental defects. Next came the congenital malformations. If many of those with chronic heart disease had not been classed by themselves, but considered with the others with congenital malformations, this category would have been in first place. Fourth on the list was tuberculosis of the bones and joints. Only a fourth of such persons could, however, claim over 50% disability. Invalidism due to pulmonary tuberculosis was classed by itself. Fifth on the list were those with defective vision, 63% of whom were totally blind. Much of the defective vision was an old age phenomenon due to such diseases as glaucoma and cataract, the incidence of which can be reduced by the application of modern methods of prophylaxis and treatment. With tuberculosis on the wane and the outlook for defective hearing much improved by advances in this field, Smith foresees a substantial reduction in Greenland's invalidism.

INDIA

Regeneration of Hemoglobin and Plasma Proteins.—S. V. Phansalkar and co-workers (*Indian Journal of Medical Research,* vol. 46, March, 1958) observed in previous experiments with vegetable proteins that supplementation of cereals with pulses and leafy vegetables improved the biological value and egg replacement value of the mixed protein in adult human beings. To compare the capacity of these mixed vegetable proteins with that of skimmed milk in their capacity to regenerate hemoglobin and plasma proteins in protein-depleted animals, they observed the changes in adult albino rats in hemoglobin and plasma protein concentration in the process of protein depletion followed by repletion. Blood and plasma volume estimations were also made along with determination of hemoglobin and total plasma protein concentration. The animals were first fed a protein-free diet, otherwise complete in minerals and vitamins. Blood volume, packed cell volume, and hemoglobin and plasma protein concentrations were estimated before the animals were placed on a protein-free diet and 4, 8, and 10 weeks after they had been fed such a diet.

The body weights decreased progressively till the 8th week, after which further fall till the 10th week was insignificant. Blood and plasma volume however changed little till after the first four weeks. The hemoglobin level showed a slight decrease in four weeks, real depletion in total circulating hemoglobin and plasma proteins becoming evident at the end of eight weeks. Protein-depleted rats were divided into three groups and kept on diets containing the following as sources of protein respectively: skim milk for the first group; a mixture of wheat, red gram, and amaranth for the second; and a mixture of bajra, red gram, and amaranth for the third. The intake of total proteins in the different groups and of calories was identical. Such diets were started after eight weeks of depletion. Blood volume, packed cell volume, and hemoglobin and plasma protein concentrations were determined in all the groups 3, 7, and 10 days after commencement of repletion and also after 14 and 21 days.

The changes in the different values occurred in an order which was exactly the reverse of that seen during depletion. Thus, blood and plasma volumes showed a significant increase within three days of repletion, while subsequently the increase was comparatively small. Body weight showed a steady rise throughout the period. On all the three diets the rats could double the quantity of total circulating hemoglobin, thus showing the efficiency of mixed vegetable protein in its regeneration. The average plasma protein concentrations in all three groups showed a rise, the rate of regeneration, however, being most rapid in the group given skim milk and slowest in those given bajra (third group); this was also true of the hemoglobin. There were no differences in the rates of gain in weight on the three diets. The regenerated hemoglobin formed 76 to 86% of the newly formed total circulating blood proteins, the rest being plasma proteins. Thus, although the vegetable protein mixtures promoted regeneration of hemoglobin and plasma proteins at slightly slower rates than skim milk, they did not lack the capacity to regenerate them. Cereal-pulse-leafy vegetable diets can therefore be used in the treatment and prevention of protein malnutrition.

Electrocardiogram of Infants.—Bharucha and Datey (*Indian Journal of Child Health*, vol. 7, July, 1958) studied the electrocardiographic pattern of 44 normal infants on the first day of life and found that the criteria for diagnosing right and left ventricular hypertrophy are not yet evident as they are in adults. Besides the standard extremity leads, they took augmented unipolar extremity leads and unipolar precordial leads. The average heart rate was 130 per minute (range 100 to 162). All infants showed sinus rhythm, but seven had episodes of sinus arrhythmia with a heart rate below 115 per minute. The average P-R interval was 0.11 second. The average P-wave axis in the frontal plane was 55 degrees. The mean QRS axis in the frontal plane was 130 degrees, and the average T-wave axis was 42 degrees. Either positive or diphasic T waves were seen in the right precordial leads of 37 infants, and in the left precordial leads the T wave was positive in 12, diphasic in 9, flat in 9, and negative in 4. The T waves in right precordial leads were negative in two and flat in five. Thus, right ventricular preponderance was manifest in every tracing studied in this series. These changes should not be confused with the findings of right heart strain due to congenital cardiac malformations.

Narcotics Department.—The report of the Opium Department, now renamed the Narcotics Department, for the year ending September, 1956, revealed that over 500,000 lb. of opium were exported, mostly to the United Kingdom and the United States. The former imported about 293,000 lb. and the latter 200,000 lb. Other buyers were France, Italy, Japan, and Germany. The number of licensed cultivators of poppies is decreasing. A few cases of illicit cultivation still occur. In the suppression of illicit trafficking in narcotics, the Narcotics Intelligence Bureau, established by the government under articles 11 and 12 of the Geneva Convention of 1936, maintains liaison with the customs, police, and excise authorities in India and abroad. The opium is processed in the government opium and alkaloid works and is alone used for medicinal purposes, the demand for which has been increasing at home and abroad.

Portal Venography in Children.—F. A. Nazareth (*Indian Journal of Child Health*, vol. 7, July, 1958) performed percutaneous splenoportal venography on 25 children under light general anesthesia. All of them had palpable spleens of varying sizes. If ascites was present the abdomen was tapped early in the morning of the day of the investigation. Eleven patients had hepatic cirrhosis, five had noncirrhotic hepatosplenomegaly, three had congestive splenomegaly, and one each had thalassemia, nutritional anemia, a displaced spleen, tuberculous peritonitis, rickets, and infectious hepatitis. In normal splenograms, the contrast medium injected into the spleen passed into hilar veins which joined to form the splenic vein. The splenic vein was seen coursing towards the liver, meeting the superior mesenteric vein to form the portal vein. From here the dye entered both sides of the liver. No collateral veins were seen. This appearance was seen in 10 patients, including the 5 with noncirrhotic hepatosplenomegaly, 2 of those with anemia, and 1 each with rickets, tuberculous peritonitis, and a displaced spleen. The size of the splenic and portal veins was normal in these patients. The rest showed three different patterns. The pattern of intrahepatic obstruction was seen in five of those with hepatic cirrhosis whose splenic and portal veins were larger than normal and who showed pooling of the dye in the liver. Collateral circulation was seen in all patients, but the inferior mesenteric vein and the inferior vena cava were not visualized. These children had a marked splenomegaly and their ages varied between 3½ and 11 years. The liver was palpable and firm and liver function tests and liver biopsy indicated cirrhosis.

The second group showed the pattern of infrahepatic obstruction. Seven patients were in this group, four of whom had cirrhosis. The other three had congestive splenomegaly. In those with cirrhosis, the dye stopped abruptly in some part of the splenic vein and the portal vein was not visualized. Collateral veins were prominently seen. These patients were aged 15 months to 12 years and had enlarged firm livers, palpable spleens, and ascites; jaundice was present in two. In patients with congestive splenomegaly, there was associated evidence of portal hypertension. No dye was seen to enter the liver, and the collateral veins were plainly visible. The splenogram was consistent with a diagnosis of cavernous malformation of the portal vein. These patients were 9 to 13 years of age, gave a history of repeated hematemesis, and had marked splenomegaly with a barely palpable liver; esophageal varices could be demonstrated radiologically in two. The third group was characterized by suprahepatic obstruction and was seen in two patients with hepatic cirrhosis and one with infectious hepatitis. The hepatic radicles of the portal vein were well seen without any distortion or pooling of the dye, and numerous collateral veins were present. One patient in this series died 30 minutes after the splenography. Extravasation of the dye into the peritoneal cavity occurred in some without any untoward effects, but others complained of transient tenderness over the spleen.

Occupational Therapy.—An occupational therapy center and workshop, the second of its kind in Asia, was inaugurated in Nagpur in July. The first is at the K. E. M. Hospital, Bombay. The new center is located in the radiology department of the Nagpur Medical College Hospital and will offer a two-year course. Twenty students will be trained in occupational therapy. A grant of about $4,200 was earmarked for the new department by the government and, in addition, $2,100 was donated by the president of the All-India Occupational Therapists Association.

NORWAY

Radioactive Fall-out.—Last spring the Norwegian State Council for Radio-Hygiene Problems was approached by the Norwegian Public Health Service, with a request for information about means of protecting the population from radioactive fall-out. The answer to this request, dated July 1, 1958, is briefly as follows: Measurements have been taken of the radioactive fall-out in Norway in 1957 and of the strontium-90 content of the bones of human beings and domestic animals. Until a full report is available, it may be said that the radioactive fall-out in 1957 did not exceed 25 to 33% of the upper limit permissible anywhere in Norway. Though the situation is serious, the available information about it is not such as to warrant taking active measures to cope with it. Apart from the radioactive fall-out, measures are already being taken to reduce the harm likely to result from other sources of radiation. As for the fall-out itself, it may already be assumed that recent nuclear explosions have increased the radioactivity of air, water, and certain articles of food to a progressively alarming degree.

Hepatitis from Blood Transfusion.—Dr. H. Heistö (*Tidsskrift for den norske laegeforening,* July 1, 1958) sent a questionnaire to 7,755 patients discharged from the surgical service of Ullevaal Hospital in 1955, asking if they had suffered from jaundice since their discharge. Of the 6,043 who answered, 977 had had blood transfusions in the hospital. Among the same 6,043 were 609 who had been jaundiced. In many of these patients the jaundice was associated with disease of the bile ducts, hepatic cirrhosis, hemolytic anemia, and other conditions not attributable to the transfusion. Only three were believed to have been caused by the blood transfusion. The incidence of hepatitis was significantly higher among the recipients of blood transfusion than among the rest and was also higher than the incidence of hepatitis of the whole of Oslo in 1955. Of the 5,066 patients not receiving a blood transfusion while in hospital, none developed hepatitis during the period under review. Thus Heistö found the risk of hepatitis small in comparison with the benefits of transfusion, but he endorsed the policy which forbids the use of donors with a history of hepatitis. He noted, however, that while one of the two transfusion centers used makes a rule of disqualifying as donors every exhepatitis patient however far back his hepatitis may date, the other center accepts donors whose attack of hepatitis dates back two years or more.

Falling Appendicitis Death Rate.—The steady decline of the appendicitis death rate in the last 20 to 30 years was graphically demonstrated in the *Journal of the Oslo City Hospitals* (vol. 8, 1958) by Dr. H. F. Harbitz who showed that prior to 1940 it was between 2 and 5%, whereas after this year it was under 1%. It has been much higher in males than in females. In his own hospital 2,696 patients were treated for appendicitis in the 10-year period 1948 to 1957. Of these 2,432 were operated on and 8 died. Of the 264 not operated on 10 died. This gives a crude case fatality rate of only 0.68%. Of the 18 deaths, 6 were traceable to incorrect diagnoses; 6 were due to peritonitis in spite of antibiotics; 3 to pulmonary embolism; and 3 to the disease being too far advanced on admission to respond to treatment. Harbitz recommended large doses of penicillin for these patients.

Perphenazine in Psychiatry.—Perphenazine was introduced in the hope that, while possessing some of the therapeutic effects of chlorpromazine and reserpine, it would not provoke their undesirable side-effects. Lingjaerde and Schjöth (*Tidsskrift for den norske laegeforening* 78:278, 1958) gave this drug to 77 mental patients, mostly schizophrenic, whose response to other forms of treatment had been disappointing. Under placebo control the drug emerged from the test with a reassuring verdict, having in many cases proved helpful after other ataraxics had failed. By varying the ataraxic given it was found that some patients responded better to perphenazine than to chlorpromazine and vice versa, but on the whole perphenazine surpassed the other drugs by exerting a more stimulating effect on apathetic patients. About 33% of them showed some side-effect and this led to the drug being withdrawn in some cases. None of the side-effects such as drowsiness, tremor, nausea, or paralysis agitans could, however, be described as serious. The daily dosage was 24 to 48 mg. The authors concluded that with later tests using a larger dose, perphenazine can often be relied on to secure better results than reserpine or chlorpromazine.

Stousland (*Farmakoterapi*, vol. 2, 1958) reached similar conclusions. Using placebo control in a series of 38 mental patients, he gave perphenazine for four weeks or more. The dosage began with 8 to 12 mg. daily, increasing at intervals of three to five days to a maximum of 56 to 64 mg. daily, the usual maximum dose being 24 to 32 mg., and the usual maintenance dose 8 to 16 mg. daily. In addition to schizophrenics, some of the patients suffered from manic-depressive psychosis. Side-effects were rare. Stousland concluded tentatively that perphenazine is well suited for the treatment of psychoses when anxiety and agitation with hallucinations and delusions are prominent symptoms.

Thrombendarterectomy for Obliterative Arteriosclerosis.—In recent years patients with obliterative arteriosclerosis at the Ullevaal hospital have been treated by thrombendarterectomy and anticoagulants. Dr. F. Bergan (*Journal of the Oslo City Hospitals*, vol. 8, 1958) stated that since 1955 the aorta, the common iliac, or the external iliac was operated on in 18 cases, and the femoral or popliteal in 58. The results in 11 of the first 18 were successful, with a peripheral pulse in the foot and without claudication. Good results could also be claimed after 24 of the 58 endarterectomies performed on the femoral or popliteal arteries with no operative death. Advanced age was no contraindication, and some of the patients were over 80. Bergan emphasized the importance of anticoagulants which have rendered operative treatment feasible.

Better Anesthesia.—One of the outstanding features of the help the Scandinavian countries give each other in medical matters is the free way in which the excellency of one of them in a particular field is used as a stick with which to beat another country. In an editorial in *Tidsskrift for den norske lægeforening* for Aug. 1, Norway and Denmark, with about equal populations, are compared with regard to the anesthesia available. With the aid of the World Health Organization and the University of Copenhagen, an anesthesiology center was established in Denmark in 1950 with the task of training anesthetists in the theory and practice of their speciality. Since then this center has become a mecca to which aspiring specialists have come. Norway alone has sent eight such aspirants for the center's one-year course. Denmark is now so appreciative of the expert anesthetist that 34 hospitals have one as a full-time member of the staff, with the rank and emoluments of a senior medical officer. In Norway there are as yet only eight such hospitals, and it has been necessary to fill some of the anesthetist appontments with applicants from abroad. The chief reason for this shortage is that the physician contemplating anesthesia as a speciality would like to be reasonably sure of a senior hospital appointment.

Relapse of Tuberculosis.—Dr. S. Böyum (*Acta tuberculosea scandinavica,* vol 31, no. 1, 1958) studied relapses of tuberculosis in the period from January, 1946, to December, 1955. During these 10 years the relapse rate rose and the death rate fell, the latter to such an extent that it was 50% lower in the last five years than in the first. Among open cases there was a shift upwards of the patients' ages to such an extent that, up to 1951, only 17% of the patients were under 40, whereas after 1951 the corresponding figure was 28%. The falling death rate and the rising average age of the patients reflected the growing duration of the disease. The relapse rate was higher for men than women, being in the ratio of 60:40 in the open cases. Relapses were most numerous between the ages of 30 and 39. No correlation of the relapse rate with the patients' ages could be established. Most of the relapses occurred on return to work and within five years of the treatment given. The relapse rate was smaller after thoracoplasty than after less radical measures such as artificial pneumothorax and conservative treatment. This study contributed little information on the relapse rate after modern chemotherapy, as it was given on an extensive scale only in the latter part of the period under review.

UNITED KINGDOM

Anemia in Pregnancy.—In a group of 1,071 women seen initially in the first 11 weeks of pregnancy, Kerr and Davidson (*Lancet*, vol. 2, p. 483, 1958) found a hemoglobin level below 10.4 Gm. per 100 ml. in 2% and below 12.6 Gm. per 100 ml. in 32%. No correlation was found between the incidence of anemia and age, parity, or the number of pregnancies within the last five years. An investigation of the efficacy of various iron preparations was carried out in 430 of these women, whose hemoglobin level was 10.4 Gm. per 100 ml. or above; 20% received ferrous sulfate, 20% received ferrous gluconate, 20% received ferrous gluconate plus ascorbic acid, and 40% formed a control group and received pills containing only lactose. Treatment was started between the 24th and 25th week of pregnancy, and the results were reviewed at the 37th week. For this follow-up, 410 of the women were available.

Hemoglobin levels and packed-cell volume rose in each of the iron-treated groups and fell in the control group, but no significant difference was observed between the changes in hemoglobin level, erythrocyte count, and packed-cell volume in the two groups treated with ferrous gluconate, with and without ascorbic acid. It was therefore concluded that the addition of ascorbic acid does not affect the therapeutic value of ferrous gluconate, either beneficially or adversely. The two ferrous gluconate-treated groups were therefore treated as one for purposes of comparison with the group treated with ferrous sulfate. This comparison showed that the rise in hemoglobin level, erythrocyte count, and packed-cell volume in the ferrous sulfate-treated group was less than in the groups receiving ferrous gluconate, the difference being significant for the erythrocyte count, barely significant for the hemoglobin level, and not significant for the packed-cell volume. There was no significant difference between the control pills and the iron pills or between the three iron preparations, so far as gastrointestinal tolerance was concerned. Thus, most of the symptoms attributed by the patients to iron medication were either incidental or psychogenic in origin.

Intolerance to Iron.—Further evidence that a large proportion of the symptoms experienced in patients taking iron preparations by mouth is psychological in origin was adduced by Kerr and Davidson (*Lancet*, vol. 2, p. 489, 1958) from the results of a double-blind trial in which 93 healthy young women were each given six packets of pills and asked to take them in the prescribed dosage during six successive weeks. Four of the packets contained, respectively, ferrous sulfate, ferrous gluconate, ferrous succinate, and ferrous calcium citrate. The fifth packet, given to the volunteers as an iron preparation, contained only lactose. The sixth packet contained lactose pills identical in appearance and composition, but marked "control pills," and it was explained that these were given to make sure that the coating used on the other pills was not itself a cause of symptoms. The results showed that there was no significant difference between the incidence of toxic effects in the four iron groups and those receiving the unknown control. On the other hand, the incidence of significant symptoms with the known control was only two. With each preparation, constipation and abdominal discomfort were the commonest symptoms; the incidence of all the others was less than 10%. As no one reported symptoms with all four iron preparations, this is taken as evidence of there being no true iron intolerance embracing all forms of iron.

Glandular Toxoplasmosis.—A series of 30 patients with acquired toxoplasmosis resembling glandular fever was reported by Beverley and Beattie (*Lancet*, vol. 2, p. 379, 1958). The parasite was isolated in four patients, and the others had dye-test antibody titers of 1:320 to 1:50,000 and complement-fixing titers of 1:5 to 1:80. All had negative Paul-Bunnell reactions. Ten of the patients were under the age of 10, 11 were aged 11 to 20, 4 were 20 to 30, and 5 were over 30. The illness varied greatly in severity and duration. Six of the patients were never really ill. The shortest duration was a week and the longest 44 weeks. In 20 patients, the first thing noticed was swelling or pain in the lymph nodes, usually in the neck. In five, so little account was taken of this that two to eight weeks passed before a physician was consulted.

Association with animals was present in several cases. One patient had contact with seven guard dogs, three of which had dye-test titers of over 1:160, but no illness had been noted in the dogs. One patient was a veterinary student who had examined toxoplasma-infected dogs post mortem. One was a carter, but no toxoplasma antibodies were found in the horses he had handled. Twelve had contact, in some cases close, with cats, and five had contact with budgerigars. In 12 cases, members of the patient's family were also examined for antibodies. The relatives of eight of these had either no antibodies or low-titer antibodies believed to be the legacy of subclinical infection years before. The relatives of the remaining four appeared to have been infected about the same time as the patient.

Long-term Anticoagulant Therapy.—The effect of long-term anticoagulant therapy in patients with coronary thrombosis was studied by Toohey (*Brit. M. J.* 2:473, 1958). Since 1955 all patients discharged from hospital after a severe attack of coronary thrombosis, or with a history of recurrent episodes of myocardial infarction, were kept on continuous anticoagulant treatment. Patients who had only a moderately severe attack of thrombosis, or who had only a single episode of infarction, were not treated. During the period under review 117 patients were given treatment. For purposes of comparison all patients with coronary thrombosis discharged from hospital between 1948 and 1955 were followed up. To obviate the possibility of bias, all those with proved coronary thrombosis discharged from other hospitals in the same area between 1953 and 1955 were followed up. The case fatality rate for the treated severe cases was 1.7%, 3.0%, and 11.6% at 6, 12, and 18 months, compared with 11.3%, 18.3%, and 24.3% for the control series from the same hospital. In other hospitals in the same area the corresponding rates were 2.6%, 6.4%, and 13.2%. These figures indicate that long-term anticoagulant therapy reduces the expected case fatality rate at all periods up to 18 months. Several of the severely ill patients on continuous anticoagulant therapy for many years died from progessive heart failure, so that while long-term anticoagulant therapy significantly prolongs life, something more is needed to halt the underlying atherosclerosis.

Long-term anticoagulant therapy is a feasible procedure and most patients can be adequately controlled if blood tests are taken not more frequently than every 8 to 12 weeks. The minimum period required for routine blood tests in the few patients who prove difficult to control is four to five weeks. Toohey does not advise a blood-mailing service. Full written instructions about all aspects of the treatment are given to the patient and his physician, particularly with regard to the risk of bleeding, frequent blood tests during intercurrent illness, and the danger of taking such drugs as aspirin, phenylbutazone, and broad-spectrum antibiotics.

Sudden Death in Infancy.—Sudden deaths in children aged two weeks to two years which might have been attributed to suffocation include more than 20% of the mortality in this age group, according to a report presented to the Ministry of Health by a committee under the chairmanship of A. Leslie Banks (*Monthly Bulletin of the Ministry of Health*, vol. 17, p. 182, 1958). The report was based on the findings in 81 sudden deaths in infancy which occurred in London and Cambridge. The histological classification of the 64 from London showed the cause of death to be tracheobronchitis, possibly of viral origin, with typically explosive desquamation in 61.5%; tracheobronchitis, possibly of viral origin, without epithelial desquamation, but with pronounced mononuclear infiltration in 11.5%; and purulent bronchitis, bronchiolitis, and bronchopneumonia in 21.2%. In most cases the standard of care for the child was good, and no evidence of overlaying could be found. Only 11 of the infants had been seen by a physician in the last three days before death. In most of these the symptoms were trivial. The sort of symptoms that were often present just before death were a slight cold, with or without vomiting. Most of these patients were put to bed as usual and a few hours later were found dead or dying. The investigation so far has not revealed a definite cause for these sudden deaths.

Genitourinary Tuberculosis.—In an analysis of a five-year follow-up of 132 patients with genitourinary tuberculosis, Band and Murray (*Practitioner*, vol. 181, p. 279, 1958) recorded a case fatality rate of 3.8%. The proportion unfit to return to work was 13.6%, and 82.6% were able to return to work within a reasonable interval after their discharge from hospital. The comparable figures for a small series (41 patients) followed up between 1935 and 1940 were a late case fatality rate of 24.5% and 39% permanently unfit for work. The routine chemotherapy used was 10 to 15 Gm. of PAS, with 200 to 300 mg. of isoniazid daily, given during hospitalization and for 18 to 24 months thereafter. Streptomycin was reserved for operation cover or for patients who did not respond to PAS and isoniazid or who, for some reason, could not tolerate one of these drugs. Most patients were given complete bed rest for three to six months and remained in hospital for three to nine months. In recent years the tendency has been to perform a total nephroureterectomy for widespread unilateral renal tuberculosis when the ureter is involved or a stricture has occurred. It was performed in 45 patients in this series. Ureterocolic anastomosis was preferred to ileocystoplasty in patients with persistent tuberculous ulceration of the bladder when the remaining kidney was threatened from backward pressure.

Only 14 patients had bilateral renal tuberculosis, but they were all young. All achieved conversion of the urine in six months, and over half of them were able to return to some form of work. The more seriously diseased kidney was removed in seven cases. With the general scheme of treatment prescribed (admission to hospital, bed rest, chemotherapy, and operation when necessary) it was found that the conversion period for most patients, when the culture for tubercle bacilli became negative, was within three months of admission to hospital. Most patients were in hospital 11 weeks before operation and subsequently for about 20 weeks. Most patients returned to work within three months of discharge.

Extension of Poliomyelitis Vaccination.—The program of vaccination against poliomyelitis will be extended in three ways: 1. The upper age-limit is to be raised from 15 to 25. 2. Children and expectant mothers who have received two injections are to be given a booster dose. 3. Inoculation is to be offered to domestic staff in hospitals as well as to physicians and nurses. The cost of the expansion is likely to exceed $11,200,000. The bulk of the vaccine to be used is the Salk type imported from Canada and the United States. It costs about 56 cents an injection. The ministry estimates that raising the age limit to 25 years will bring in 6,250,000 more people, necessitating 12,500,000 injections. Hospital staff now eligible will number about 500,000. Introduction of the third booster dose will add another 6,500,000 injections to the program.

Surgical Wound Infection.—J. B. Kinmouth and coworkers (*Brit. M. J.*, Aug. 16, 1958) studied the ventilation of the operating rooms in St. Thomas's Hospital, London, and found that the bacterial content of the air declined after the introduction of a cross-draft of fresh filtered air over the operating table. This reduction in bacterial content occurred in a room in which a plenum positive-pressure ventilation system was already in operation. No corresponding reduction occurred in the rate of postoperative wound sepsis in patients operated on in this room. They concluded that the presence of wound infections can be attributed to several possible causes. One is the acquisition of hospital staphylococci by patients in the wards before operation. The organisms were found in the nose, on the bedclothes, or on the skin. Reduction of the bacterial content of the air in operating rooms is desirable as a general principle but is unlikely by itself to eliminate infection. A simple and practical test to detect the more dangerous carriers of organisms in hospitals is needed.

Report on Irradiation.—The Medical Research Council reviewed the United Nations' radiation report and found that, in general, it agreed with that of Great Britain and of the United States, both of which were published in June, 1956. In the two years since the council's report, much more information has been collected, but this has led to no major reversals of opinion. The council's report agrees that for every small additional exposure to radiation there is a small but proportional increment in the frequency of mutations in the germ cells. These will manifest themselves as genetic changes in future generations; but scientific opinion is still divided as to whether there is a threshold for radiation effects on ordinary body cells. The council stated that it is not possible to say "yes" or "no" on this point and the scientific attitude to it should be one of suspended judgment. The council took exception to the United Nations' statement that "malformations have been observed following exposure of pregnant women to accidental and therapeutic irradiation and to diagnostic procedures." No evidence has been produced that the doses of radiation used in diagnostic procedures have produced congenital malformations in the child.

Citrate Intoxication.—Ludbrook and Wynn (*Brit. M. J.* Aug. 30, 1958) found high plasma citrate levels during the infusion of citrated blood into four patients undergoing operation under hypothermia. One patient died with signs attributable to citrate intoxication. A direct relationship between the rate of infusion of citrate and the rise in plasma citrate level was demonstrated in normal human and canine subjects. For each milligram of citrate infused per kilogram per minute, the rise was about 20 mg. per 100 ml. in dogs and about 12.5 mg. per 100 ml. in human beings. By using a constant infusion technique it was shown that in dogs 40% and in man 20% of the infused citrate was excreted in the urine, and the remainder was metabolically destroyed. In both dog and man hypothermia of 28 to 29 C was shown to reduce the rate of metabolic destruction of citrate by 30 to 40%. The infusion of citrated blood at less than about 1 pt. (450 ml.) in five minutes in an adult is unlikely to cause a dangerous rise of plasma citrate, provided that the rate of citrate metabolism is not reduced.

H-Bomb Exposure and Leukemia.—A naval officer who served on Christmas Island during the nuclear test explosion there last November died of leukemia and aplastic anemia. He is the second member of the British forces who was at the Christmas Island test to die from leukemia. The disease can be caused by atomic radiation but the admiralty stated officially that from the information available there are no grounds for considering that the fact that this officer was serving on Christmas Island last year had any bearing on the cause of the illness from which he died. Also, a jury at Swansea returned a verdict of death from natural causes on the soldier who died of acute lymphocytic leukemia. A pathologist said there was no connection between his death in June and the fact that he served in the same Christmas Island test. When the pathologist was asked if he could be absolutely certain that the man's death was not related to fall-out from the explosion, he replied: "That would be to claim infallibility." The soldier was at what scientists described as a safe distance from the explosion on the island and had not been detailed to go into areas where radioactive material was kept.

Death from Hypotensive Drug.—Pentolinium tartrate, a ganglionic blocking drug, was prescribed by the resident for a 64-year-old patient, hospitalized for treatment of his hypertension. The instruction "40 mg. three times a day" was written on the treatment card, but the method of administration was not stated. The two senior ward nurses were off duty, and the remaining nurse had had no experience with pentolinium. Finding no tablets of the drug, but only a solution of it, she injected 40 mg. intramuscularly. Five minutes later the patient complained of abdominal discomfort and dizziness and his blood pressure could not be recorded. Although therapy with levarterenol raised it for a short time, he died six hours later. Autopsy showed the presence of a recent blood clot two inches from the origin of the anterior branch of the left coronary artery. The pathologist gave the cause of death as coronary thrombosis following the administration of a hypotensive drug. The coroner stated that the physician in charge should have left specific directions for the administration of the drug.

Experiments on Animals.—All experiments on living animals must be recorded and licensed by the Home Office. According to its annual report, nearly 3 million such experiments were performed in Britain last year by 4,115 licensed persons. Those holding licenses numbered 5,762. About 87% of the experiments did not require an anesthetic and were mainly inoculations or involved changes in the animals' diet or the administration of external application of a drug. Over one million experiments were done in connection with preparing, standardizing, or testing serums, vaccines, or drugs, as required by law. Most of the tests were made on rodents; only 13,750 experiments were made on cats, dogs, and larger animals. During the year inspectors paid 1,653 visits to registered laboratories, usually without previous notice, and found that in general the laws relating to animal experimentation were being obeyed. There were only five cases of irregularities, but in none of these was there any deliberate infringement of the law. They were due to carelessness or inadequate supervision.

Toxoplasmosis.—Toxoplasmosis, which has always been considered a rare disease in Britain, may, in its subclinical form, be more common than is generally supposed. Beverley and Beatty estimated that about 7% of cases clinically diagnosed as glandular fever with a negative Paul-Bunnell reaction, were in reality due to Toxoplasma infection of the lymph glands (*Lancet* 2:379, 1958). They reported 30 cases of acquired toxoplasmosis resembling glandular fever. In four of these the parasite was isolated, and the others were proved by means of the cytoplasm-modifying dye test at titers of 1:320 to 1:50,000 and by the complement-fixation test at titers of 1:5 to 1:80. The Paul-Bunnell test was negative in all cases. It is difficult to know what titer should be taken to signify active infection. The authors suggested that titers found in clinical toxoplasmosis might be accepted or titers above those found in normal subjects. Ten of the patients were under the age of 10; 11 were from age 11 to 20; 4 were from 21 to 30; and 5 were over 30. Lymphocytosis was found in 15 patients, and cells of the glandular fever type were reported in 5. The severity and duration of illness varied greatly. Five of the patients were never really ill, whereas in the others the illness was prolonged for weeks or even months. In one it lasted 11 months. Fatigue was a prominent symptom in these patients. A particular danger is the development of toxoplasmosis during pregnancy, because the infection may be passed on to the fetus while the mother's infection may be unnoticed or undiagnosed. Human toxoplasma infection may come from a variety of birds and mammals, and the disease may be transmitted from person to person. Since the commonest manifestation of acquired toxoplasmosis so far recognized is lymphadenopathy, which usually begins in the neck, it is suggested that infection takes place through the mucosa of the tonsillopharyngeal region.

Pharmacists' Remuneration.—The Committee of Public Accounts in its annual report stated that it was disturbed by the excessive profits of pharmacists on prescriptions under the National Health Service. A pilot inquiry showed that these excess profits have continued since 1954, when the Treasury first drew attention to the matter. Pharmacists receive for each prescription a dispensing fee, the cost of ingredients plus 25%, and certain other allowances. In addition many pharmacists obtain substantial discounts from list prices, the benefits of which are not passed on. Results of inquiries suggest that they may make a concealed profit of nearly 20% beyond that agreed on with the Ministry of Health.

Hospital's Spending Criticized.—The Committee of Public Accounts is severely critical in its annual report of the board of governors, the University of Oxford, and the Ministry of Health for their handling of the scheme for the extension and modernization of the Radcliffe Infirmary, Oxford. In 1955 the ministry obtained treasury approval to spend $1,116,292 on the project. By 1956 the treasury was told that the estimated cost had risen to $2,282,000 and that the hospital's board of governors had proceeded with much of the work without the ministry's sanction. The treasury consented to the proposed expenditure and gave the ministry authority to proceed with work already begun, but a directive was issued that any further expenditure could not be incurred without the consent of the Minister of Health. In spite of this, the board of governors of the infirmary placed contracts not covered by ministerial authority, and now the total expenditure is likely to be more than 2,800,000 dollars. The Ministry of Health stated that, even so, the hospital would cost no more than if it had been planned in the orthodox way, but the Committee of Public Accounts believed otherwise and considered that substantial economies could have been made if the whole project had been properly planned in advance. It considered the Ministry of Health's supervision of its agents, the hospital board, to be inadequate and recommended that the ministry's arrangements for the financial control of large hospital building projects be revised.

Refsum's Syndrome.—Three cases in the same family of a rare familial syndrome, first described in Norway by Refsum, were reported by Ashenhurst and co-workers (*Brit. M. J.* 2:415, 1958). Only one case has been reported in Britain before. Refsum's syndrome is characterized by atypical retinitis pigmentosa, chronic polyneuritis-like symptoms, cerebellar disturbances, and other neurological abnormalities. Pigmentary changes are usually absent or insignificant in the retinitis, which is associated with night blindness and concentric limitation of the visual fields. The polyneuritis-like symptoms progress to distal paresis of the limbs, and the cerebellar manifestations include ataxia and nystagmus. Other neurological abnormalities sometimes but not constantly found are neurogenic deafness, anosmia, abnormalities of the pupillary reactions, and a high protein (globulin) level in the spinal fluid. Other findings are ichthyotic skin changes and abnormalities in the electrocardiogram, such as an increase in the P-R interval, nodal and auricular extrasystoles, alterations in the QRS complex, and sinus tachycardia. Consanguinity is present in nearly all cases.

Owing to the rarity of the condition, few autopsies have been done. The main abnormalities observed are fibrous thickening and infiltration of the leptomeninges by lipid macrophages and fatty degeneration of peripheral nerves, with axonal degeneration of the fiber tracts from the pontobulbar region to the cerebral white matter. In the authors' first patient the condition was provisionally diagnosed as a case of Friedreich's ataxia. The ocular signs, progressive limb paresis, and abnormal spinal fluid prompted further investigation, and Refsum's syndrome was diagnosed. Examination of two siblings revealed that they too had the syndrome. One, a woman of 23, who complained mainly of loss of power and shooting pains in the limbs, suddenly died while under investigation. The other, who suffered no disability, had lesions referred mainly to the skin, eyes, and peripheral nerves.

Cancer in Africa.—It is generally thought that cancer is rare in Africans and that the types and sites of cancer vary widely in their frequency from those seen in Europe or America. In 1951 the Faculty of Medicine of Makerere College set up a Cancer Research Committee to study the incidence and types of cancer in Uganda. A preliminary report was made by Davies and co-workers (*Brit. M. J.* 2:439, 1958). As might be expected, difficulties were encountered owing to the limitations of language and education of most of the population. Patients in Uganda do not always know their age, and their follow-up is difficult owing to migration from one area to another. There is also some reluctance, particularly in the elderly, to attend the hospital for advice. Preliminary analysis revealed that cancer is as common in Uganda as in European countries. In fact, the incidence of all malignant tumors in the Kyadondo region is of the same order as it is in Denmark. The chief exception was that women over 45 years of age in Kyadondo have half the cancer incidence of Danish women 45 to 54 years of age. The corresponding rates for men are very similar. There is an excess of hepatic cancer in Uganda, but only in men. Malignant disease of the lymphatic system is twice as common in African men as in the European, but not in African women. Gastrointestinal cancer, on the other hand, is only half as frequent in both sexes in Africa as it is in Denmark. Nephroblastoma (Wilms' tumor) and cancer of the penis are more common in the African. Cancer of the sexual organs is less common in African than in European women.

Antibiotic Hazards.—Disasters with antibiotics continue to be reported. A verdict of death by misadventure was recorded in Newcastle on a patient who died after an intrathecal injection of penicillin, given for meningitis. The doctor checked the content of the syringe before giving the injection by questioning the nursing staff, but confusion arose over the meaning of "mega unit," with the result that the patient received a dose 500 times that intended. An hour after the injection the patient started to have convulsions, and although measures were taken to dilute the spinal fluid concentration, he died. The coroner found that death was due to acute meningitis aggravated by the penicillin injection. At another inquest a patient was found to have died from aplastic anemia caused by streptomycin. A woman with pulmonary tuberculosis was hospitalized for two months and given streptomycin, para-aminosalicylic acid, and isoniazid. She left against medical advice but was readmitted two months later, when treatment with streptomycin and isoniazid was resumed. Within a month symptoms of aplastic anemia appeared, and she died 10 days later. Although rare, this can be caused by streptomycin.

WORLD HEALTH ORGANIZATION

Aging Population.—The WHO advisory group on the public health aspects of aging populations agreed that adequate provisions will have to be made for the tremendous increase, proportional and absolute, in the number of old people in the community. Because in many European countries fewer babies are being born, the proportion of old people in the population is increasing. Through improved social conditions and medical care, more people are living longer, but it is not sufficient to save life—life for those saved must be worth living. Although the population of 574 million people living in Europe and the U. S. S. R. in 1950 is expected to increase to 947 million by the year 2000, most countries have so far made no coordinated efforts toward solving the medical, social, and economic problems arising from the steady increase in the number of the aged. The following recommendations were made. It should be determined whether retirement has an adverse effect on health. Standards for physical and mental fitness related to various occupations for the elderly must be formulated. The nutritional needs of the elderly must be established. Health education related to old age problems and the collection of statistics concerning diseases among the elderly must be improved. Occupational guidance should be available to persons before they retire, and alternative employment, perhaps part-time, should be available for the elderly, if desired.

Regarding housing for the elderly, a definite policy must be formulated. Small ground-floor apartments are perhaps the most convenient. Special attention should be given to preventing traffic and home accidents. Housing for the elderly should be in accord with local customs and previous patterns of living and should receive the same careful planning as for all other age groups. The elderly should not be isolated. Better training in nutrition and dietetics is needed for those who are responsible for meals for the elderly. Care for the aged is not a matter of charity but of social justice. The aged are full participating members of society, who have a right to choose freely how they wish to live, and when possible to take care of themselves as long as they desire.

Peaceful Uses of Atomic Energy.—According to the second U. N. International Conference on the peaceful uses of atomic energy, in the minds of people everywhere atomic energy remains a threatening and mysterious force, interpreted very often in magical rather than rational terms, and fraught with irrational fears of serious social and individual consequences. The first chapter of the report of the conference examines the question of harmful effects of radiation on brain function. Data are scanty. Work, however, has shown that though nervous tissue is among the most resistant of all tissues, it can be severely damaged by large doses of radiation which the subject can survive. Experimental work on animal embryos and young animals has confirmed the radio-sensitiveness of nervous tissue during the developmental period. The adult brain, however, is exceptionally resistant to radiation. Thus, with the low doses of radiation to be encountered in the peaceful uses of atomic energy, the organic brain effects so far observed are of minor or no importance.

In advanced countries, a second industrial revolution might interfere with whatever social equilibrium and stability has been achieved. Societies have a certain threshold of tolerance for rate of change, which, if exceeded, leads to some measure of social disorganization. Still greater concern is expressed about the effect on underdeveloped areas, where the advent of atomic energy, to the extent that it accelerates the process of industrialization, can bring an increase in existing social problems. Where exaggerated hopes have been aroused, there may be disappointment and disillusionment when nuclear installations do not prove feasible or do not produce at once a miracle in the form of a higher standard of living. The repercussions from eventual disappointment may be severe and take the form of hostility against those populations which derive major benefits from atomic energy. Much will depend on the attention given to human factors in planning and development.

Evidence about emotional reactions to atomic matters is frequently found in the day-to-day conversation of people. Disagreeable weather or failure of the harvest are often blamed on atom bomb tests. Fears of the fall-out, disposal of atomic waste, pollution of water and milk supplies, and sterility or harmful genetic effects are direct expressions of anxiety. These fears conflict with many official announcements put out about risks and safety measures. It would be dangerous to ignore the fact that the emotions aroused in the public by the peaceful uses of atomic energy cannot be separated from fear and anxiety stemming from the nuclear bomb. The anxiety-producing qualities of atomic energy are ascribable to the peculiar nature of radiations—unseen, unheard, untasted, unsmelt, unfelt, and, as far as the individual is concerned, uncontrollable. Surrounded by confusion and fears, people immediately look for a scapegoat. The public, unable to distinguish between the physicist, biologist, etc., or between a scientific fact and a scientist's opinion, is confronted with apparent contradictions. Widespread publicizing of mistrust and disagreement among scientists, not only in connection with nuclear energy but also in such matters as poliomyelitis vaccine and the carcinogenic effects of tobacco, enhances this effect. Scientists do not make the task easier when they vacillate between statements limited to their scientific competence and those which have the mantle of science but which are actually policy decisions.

The relations of the scientists to the politicians also generate anxiety because of the uncertainty as to who wields the power and how. In one sense, the political leader has power over the scientists, but in another he depends on the scientist and hence is in his power. The advent of nuclear power has taken the ultimate strength out of the hands of services which are under political control and placed it in the hands of the scientist. The scientist is a civilian and not in the direct service of the state and in his role of scientist owes his first allegiance to scientific truth. As a scientist he has had no special training in discipline and obedience. It is not unnatural, therefore, that political leaders sometimes develop intense hostility to the scientists and so promulgate unrealistic decisions in attempts to control a scientific situation. Few, if any, political leaders have had enough scientific training to enable them to see the ultimate implication of scientific work. The effect is general bewilderment and a suspicion that the political leader, instead of being master of the situation, is, in fact, caught between the scientist and the next election. The relationship between the scientist and the politician requires serious study.

Since the public mainly learns about atomic developments from the press, the role of the journalist is very important. The experts were impressed by the general standard of integrity with which journalists handled atomic energy news, yet this news was often regrettably presented under scare headlines which left an enduring impression, even if the substance of the story was sober and even reassuring. The tacit newspaper principle is that bad news is good news, and this has profound implications for mental health and morale.

CORRESPONDENCE

INFECTION AND LYMPHOID LEUKEMIA

To the Editor:—On Sept. 1, 1956, four children of a family developed diarrhea and vomiting. Three of them recovered after seven days. The fourth sibling continued having diarrhea and anorexia. About 14 days after this illness began, the mother noted that he was pale and that he had some bluish spots on the skin. Seventeen days after the illness, examination disclosed that he had generalized petechiae and ecchymosis and a markedly enlarged liver and spleen, a hemoglobin level of 5 Gm. per 100 cc., and a white blood cell count of 70,400 per cubic millimeter with no polymorphonuclear cells and 100% large lymphoblasts.

Accordingly, a diagnosis of lymphoid leukemia was made, and the child was treated with blood transfusions, aminopterin sodium, mercaptopurine, and prednisolone. On Nov. 11, he had a remission, after 10 days of therapy. During this remission bone marrow examination showed no evidence of leukemia.

On Jan. 1, he had an exacerbation of his leukemia, with an elevation of the white blood cell count to 68,000 per cubic millimeter and a fall of the hemoglobin level. At this time bone marrow examination showed numerous lymphoblasts and stem cells. He had another remission after this, which lasted until March 11, 1957, when he was hospitalized again for blood transfusions. He again had a remission which lasted until March 21 when he was given another transfusion. About April 10 he developed fever, nosebleed, and a severe anemia. He finally died on April 14, 1957. Postmortem examination showed foci of immature lymphocytes scattered through the spleen, lungs, liver, and kidneys.

The other three siblings were examined on Oct. 4, 1956. One child, aged 6 years, had a white blood cell count of 5,800, with 26% polymorphonuclear cells, 72% lymphocytes, and a normal blood smear. Another child, aged 3 years and 6 months, had a white blood cell count of 7,200, with 35% polymorphonuclear cells, 58% lymphocytes, 2% eosinophils, and a normal blood smear. A third child, aged 8 years and 9 months, had a white blood cell count of 6,100, with 52% polymorphonuclear cells, 44% lymphocytes, 4% eosinophils, and a normal blood smear. It seems theoretically possible that these four children were all victims of the same infections agent from which three of them recovered, but one of them went on to develop an acute lymphoid leukemia.

SELF-ADHERING NYLON TAPES

To the Editor:—A new nylon tape has been found which has widespread clinical application. A Swiss inventor, Georges DeMestral, became entangled in a patch of burs when he was out for a walk. Why did the burs stick to his clothing? In collaboration with a Swiss loom builder, he created synthetic burs. These tape strips are made up in two sections, one a bristle, or male surface (composed of thousands of microscopic hooks), the other a matted pile or female surface (composed of thousands of microscopic loops). The latter is sewed or stapled on as the recipient or bottom layer on whatever material is used. After the fitting on of a bandage, blood pressure cuff, brace, brassiere, diaper, knee cap, splint, or surgical garment, by overlaying the bristle portion and gently rubbing the hand across the apposing surface, from the outside, this bristle tape will lock into the position in which it has been applied to the matted surface.

These tapes can be used again and again. Certified tests by the Better Fabrics Testing Bureau, Inc., have shown that the tape can withstand 5 dry cleanings, 20 launderings, and ironing up to 300 F and that they have marked tensile strength. This method has been used in lieu of zippers and buttons to close various outer garments in the men's apparel field. This material comes in various colors, is from ¾ to 2 in. wide, and is supplied in rolls as a ribbon tape.

Clinically, I first used these tapes when a patient required a metacarpalectomy for construction of a three-fingered hand. Because she had difficulty in applying the ordinary elastic wrist band, with snaps, for compression through the metacarpal region, this new material was sewed onto an elastic wrist band. The patient had no further difficulty in applying it for compression.

These nylon tapes can be used to replace zippers, snaps, slide buckles, safety buckles, hooks and eyes, eyelets, shoe hooks, garter supporters, buttons, safety pins, metal clips, toggles, tie tapes, and adhesive tape. They are trade-marked by Velcro Sales Corp., New York, and are in short supply, but they should soon be readily available for clinical use.

MISCELLANY

ARE WE MAKING THE SAME MISTAKES BRITISH DOCTORS MADE?

THIS BRITISH GP THINKS SO

Reprinted with permission from California GP, *June, 1958.*—Ed.

Almost every doctor who visits England comes back wanting to write an article or give a speech about socialized medicine. Because there has been so much said so many times on the subject, it has lost much of its interest.

Yet, the Academy Headquarters in San Francisco recently had a visitor from England who had some startling, frightening things to say of interest to every American doctor.

The visitor was Dr. Alastair J. Marshall, Luton, England, who is visiting in this country under a Ford Foundation Grant. As an area executive in the British Medical Association and on the executive area council (⅓ doctors, ⅔ laymen) for the national health system, Dr. Marshall can competently speak on this subject. Here are some of the questions presented to Dr. Marshall by the Academy's Executive Secretary Bill Rogers.

Did the doctors try to get together to present a united front against socialization?

Indeed they did. The British Medical Association polled the doctors and stated the act was completely unacceptable. In an initial poll only 17 percent indicated they might favor or go along with the national health act.

When the government was faced with the prospect that 83 percent weren't going to participate, what did it do?

They shot back at the BMA saying they proposed to go ahead with the 17 percent who would participate. They pointed out to the negotiators that the first people signing up would be given immediate seniority, that pensionable rights would be from that day. But the thing that really bulldozed the doctors was that during a very limited time period the government offered to buy the "goodwill" of the practices of doctors who would sign up. When they re-polled the doctors after this was announced 47 percent said they would sign up.

Do you have any idea how many of the doctors are specialists in England?

About one-seventh or one-eighth are specialists.

Has nationalization had any effect upon the number of doctors entering general practice or the specialities?

Initially there was a rush of people into specialty ranks because it appeared they were going to do considerably better. Now, everything is in a state of confusion. These young people having spent as many as 10 years as registrars (they work in hospitals as residents at a very low salary) find there are no jobs available. Many of them would like to get into general practice but find that general practitioners aren't anxious to have them either. The internists have the biggest problem.

The average GP in this country does obstetrics, pediatrics, common surgery and medicine. How does this compare with the GP in England?

Well, we do no surgery at all—the specialists have succeeded in seeing that no general practitioner has access to any hospital. The people are now conditioned to expecting specialist surgery. We do obstetrics. Most of it. That's not because the government thinks it's a good idea but there have been no hospitals built and there are no places to put these people. We know their intention is to take obstetrics away from us too once they get hospitals built.

How many GP's had hospital privileges before the government took over?

Many.

I've heard you have a bed shortage. Do you agree?

Yes! Our patients expect to wait two years for the removal of tonsils, two or three years for a chronic appendix; they will certainly wait that long for a gall bladder or a gastroectomy. Emergency surgery is done just as it was before when it is needed.

You would think this would produce a lot of private work.

True, but it is mostly in the consultative field.

Do you think socialization was forced mostly by the labor government?

No. They brought it in but it was a coalition government that started the program. Winston Churchill himself welcomed the advent of the national health service.

How have drug manufacturers fared under socialization?

Initially, very well. Now they are finding more of a "hard sell." The first few years it was wide open and anybody could prescribe anything they liked. As soon as costs rocketed the government made restrictions. Now doctors are very wary about prescribing new products since the doctors may end up having to pay for the drug themselves. The drug companies must enter into price agreements. In fact we get directives not to use certain drugs because the companies have not entered into agreement.

How many patients a day do you see now—how many were you seeing before?

Because of my commitments I have a full list and have 3,600 patients. Any patients above that I'm not paid for. Sometimes I'm forced to take on new patients such as when twins are born to a family and if I'm a friend of theirs and want them to remain as my patients. I get in my office around 8:30 in the morning and will work until noon and will see 40 to 50 patients. I'll certainly see 50 or 60 in the evening. I'll have 20 to 30 home visits. This makes a total of about 120 to 140 a day. In the old days I used to see around 35.

What's the basis of your payment?

I'm paid solely on the basis of number of patients on my list, not the amount of work I do. Besides this we're paid 65 cents for series of immunizations and we receive a delivery fee of $21. There is nothing else we get paid for.

If the government doesn't like the way you practice what can they do about it?

They can fine you after a warning. They'll do this if a patient complains you were rude, wouldn't make a house call or if the government inspectors don't find your office up to par. They will also fine you for prescribing a drug which is not approved by them.

Are hypochondriacs a problem?

They're a dreadful problem. We're knee-deep in them. The national health system has increased the neurotics considerably.

Why don't you refer some of these patients to a psychiatrist?

It's almost impossible to find one. Especially one who's sane enough to be able to go to his clinic. The psychiatrists are few and far between.

But you can dismiss patients can't you?

Yes, but I have to consider my pocketbook, family –and reputation.

Do you think the majority of the public is satisfied?

This is difficult to assess because of the conditionng everybody had with the emergency medical service during the war. I don't think they are satisied or dissatisfied. The majority just don't seem to care.

Under such a plan as this people are getting more medical care than ever before. If you discount what it's costing do you think they're getting BETTER care than prior to 1948?

Oh no. The over-all care probably is better because of those who couldn't afford any kind of care before. But almost every doctor will admit that the quality of his work has deteriorated, simply because of the mass of people that seek medical advice even for the most trivial complaints.

What effect has this had on medical education?

Well, the government was smart. When the national health act first came in they also brought in an education act which made it easier for anyone to go into medicine. In the last two years it has become very apparent this lovely "springtime" has fallen flat. Now there is a falling off of people going into medicine. I would certainly not advise my son to go into medicine today.

Where do you feel you British doctors made your biggest mistake in letting the government take over?

We were not unified and simply didn't stand firm against the government. Our lines were broken here, there and everywhere. We all feel the government would never have gone ahead with this system if we had any unification within our ranks. But ours being an individualistic profession everybody had ideas of their own and you never could get three people to agree with each other.

How effective has the BMA been in getting reforms and improvements?

Rather ineffective. The trouble is it's always approached the government completely on *ethical* lines. Now about 80 percent of the doctors belong to what we call a "guild." I suppose you might call it a union, but we don't like that term for a professional group. Because of its charter the BMA is not allowed to participate in politics and that's the reason we had to form the guild. The BMA could have been much more effective if it had the power we have given to this British Medical Guild.

How does the guild work?

It really hasn't had an opportunity to work yet. Each doctor, however, has signed a firm pledge that he will abide by the actions of the guild. If doctors are going to let each other down, then we might as well forget about the whole thing. If the guild should ask its members to resign in any given area, it will upset the entire national health plan and will be a very strong bargaining force. We'd continue to see our patients, of course, at a very low fee but would refuse to do any of the paper work. The doctors in the rest of the country would be contributing to the general fund of the guild to help support the doctors who won't be receiving anything from the national health fund. We have just about discovered the only way to fight a government is through trade union rules.

Like England there are a few doctors in this country who would not oppose government control in medicine. What advice would you give to the majority who want to see freedom in medical practice maintained?

I only wish that the AMA could finance a tour to send those doctors (who would favor a national health service) to England. Idealistically it's a wonderful thing that everybody can have free medical care and attention. But in practice it just doesn't work. The cost has rocketed about three times what it was thought the maximum costs would be. The government obviously didn't realize so many people would take advantage of it and take advantage of it so often.

What would you guess the gross annual income is for a general practitioner?

As a single practitioner his gross would probably be between $8,000 to $10,000 a year. Out of this he would have to pay for his office, equipment, car, his secretary, utilities and tax which would bring him down to a net of $5,000 to $6,000 a year. In a group a doctor can do better since you share expenses.

What about the incomes of specialists?

From the government most of them get, depending on the amount of hours they put in, around $10,000 a year. This gives them quite a bit of free time for consultative practice so they can do much better. Oddly enough they get the same income no matter what their specialty is. The eminent brain surgeon will receive just as much as a dermatologist: Internists have the biggest problem since there are many more of them than there are positions open. Those working in the hospitals waiting for a consultative post to open (some have now been waiting ten years) make around $5,000 a year.

From your own personal travels in this country do you feel we are following in your footsteps?

Unfortunately, yes. I feel the same pattern is reproducing itself here. And what is more I have seen very little evidence of your profiting by our mistakes. There is a similarity in the way governments work and you could learn much from our example.

I know you are acquainted with our Forand Bill. From your experience how do you think American doctors should approach this type of legislation?

If American doctors don't feel this is the best type of medicine for their patients they should oppose it now. But you can't do this unless you're unified—and you are *not* unified. If you Americans benefit from our experience you'll remember the words of your own Ben Franklin: "We must all hang together, or assuredly we shall all hang separately."

What is your hope for the future as far as England is concerned?

I think it's more than a hope. Within the next two years there will have to be considerable modification or we will quit. Having had 10 years of this we are much more united now than we were in 1948. At this very moment the government and the medical profession have reached a deadlock. We were on the verge of a walkout when the government set up a Royal Commission (an independent body of prominent lay citizens) to reappraise the entire program. We are now waiting for the report of the commission to see what we'll do.

Do you think most British doctors would share the views you've just expressed?

Definitely. I prepared a talk expressing most of these views before I left. To get reactions I showed a copy to both a conservative and then to a very socialistic minded doctor. Both agreed with *everything* I said. But this was what was interesting. The conservative added: "If you have any influence on American doctors you will be moving them along towards socialism." While the socialist exclaimed: "If American doctors should really take to heart what you've said, socialization of medicine in the United States could be set back 50 years.

WELFARE STATE DOWN UNDER

L. D. Hotchkiss

Reprinted with permission from the Los Angeles Times, *July 13, 1958.*—Ed.

AUCKLAND.—It's quite a change from the balmy trade winds of the tropics to the sharp blasts of winter now ruling the Land of Down Under. You go from verdure, beauty and carefreeness to sodden skies, trees barren of leaves, and people with unsmiling faces.

At this point I wish to emphasize this is no expert appraisal of New Zealand, its people, or their problems. Any person who spends only three days in a country and can diagnose its ills and prescribe immediate remedies is either a bloated egotist or a plain idiot.

All I can report on New Zealand is what I saw and what information I gained from talking with its people.

The people I talked with were friendly, sturdy, spoke more understandable English than the Australians, but gave the appearance of being tired of it all.

And Auckland—a city of 400,000—is drab looking, there is a power shortage, business is not good, but the back country is beautiful.

New Zealand today is the complete welfare state —from the cradle to the grave.

The trend started years ago and has been growing ever since. Recently a truly Socialistic government came into power and Valhalla has been reached in the eyes of the dreamers.

Already "blessed" with socialized medicine, state-operated hospitals, clinics, etc., the present government recently voted burials free of charge. Now they have the complete cycle of life on the cuff, the dreamers believe.

But taxes are extremely high, hotels have no rooms with bath, no new building of any consequence except state construction has taken place for years, and the place gives you the impression of being 25 to 50 years behind the times.

So afraid of the flight of capital is the government that a person may take only $400 out of the country. As a result New Zealanders do little traveling outside their own country.

This causes them to be quite provincial, which is no sin, but with the world moving so fast today you can't bury your heads in sand.

New Zealand is a member of the British Commonwealth of Nations.

They have sent their manpower to fight in two wars for the mother country and they fought well.

After the fall of Dunkirk, they shipped every firearm and every bit of ammunition they had to aid in England's hour of greatest peril.

Still they don't like the English immigrants too well.

"They are too bossy and they think they know everything," one New Zealander told me.

Furthermore they opened their hearts and their country to Hungarian refugees, and now they wished they hadn't. They don't understand the Hungarian and the Hungarian doesn't understand them.

Met at Auckland by one of 20th Century-Fox emissaries—through the courtesy of Harry Brand, the publicity chief who always looks out for newspapermen—we were taken on a tour of Auckland.

Our chauffeur was a native who never had been beyond the shores of his country. But he was polite, talkative, and for the welfare state hook, line and sinker.

He was, I thought, a little hepped on the matter of state housing. The state, it seems, has built most of the homes for the past 20 or 30 years and he showed us all of them. They are built of brick and all look alike. A request for a view of the best residential district of Auckland landed us right in the middle of another state housing project. Then he showed us state hospitals and state-operated homes for the aged. And although I wasn't feeling any too good, and am not a 3-year-old any more, I couldn't seem to get interested.

We went to the top of one tree hill which provided a magnificant panoramic view of Auckland and its harbor. Then we proceeded to Ellerslie race course, the most beautiful steeplechase track I ever saw. There was no racing the day we were there but the turf was the most meticulously kept I have ever seen, with due apologies to Santa Anita.

One end of the course is enhanced by a stiff hill and the steeplechase which was run the Saturday before we arrived was a four-and-one-half-mile affair and the winner took the jumps, climbed the hill, and carried 160 pounds.Winners have carried as high as 190 pounds—all of which will be sad news to trainers and owners at Hollywood Park who scream and sulk at 130 pounds for seven furlongs.

A great war memorial building stands high on a hill and can be seen for miles at sea. The New Zealanders can be justly proud of their war records. But the last conflict broke them. They insisted on paying their own way and also dropping generous sums in England's always hungry kitty.

We had a tremendous base there during the war in the Pacific, and New Zealanders proudly point out the remaining cantonments once occupied by the Americans. They rather liked us, but I don't think they ever quite understood the average American trooper. He was too free with his money and too popular with their womenfolk.

All the above happened on our first visit. The Mariposa returned from Sydney to pick up cargo, disembark and embark passengers.

With only a few hours at our disposal we hired a private taxi, piloted by a native Maori, and asked him to take us into the back country of Auckland.

A more beautiful country we had never seen. The soil is rich and it can grow almost anything. The farmhouses get away a bit from the state models in Auckland, and it really appears to be a rural Utopia.

But the tillers of the soil have a tough time making a living. They have few markets save their own and Australia.

From the taxi driver, a native of this island, we learned the mood of the people today.

The state practically runs everything. Private business operates, to be sure, but the heavy hand of state in the form of taxes and regulations stifles investments, shuts off initiative and blocks progress almost at every turn. The financial situation is so serious that just recently New Zealand had to go to her neighbor Australia for a huge loan.

"It's the younger generation we worry about," said our taxi driver. "They haven't the ambition we had; they run in gangs and they don't look to the future. They say the state will take care of them."

Somehow this statement has a familiar ring.

And perhaps we should send some of our penthouse dreamers over to live in New Zealand for six months. Their ideas of Utopia might undergo a sharp change.

As for the New Zealanders themselves we must hope and pray that the lights go on again for them, despite their Socialism.

They are our kind of people and they live not too far from the menacing Red hordes of Asia.

Personally I would like to see us take some of our loose change we are spraying around in Commie-controlled countries of the world and get it to the people of this great land.

I said people, not government.

BUSINESS PRACTICE

This is the second in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

SELECTING THE PLACE TO PRACTICE

One of the first big decisions a physician must make is where to practice. Selection of a location should be made on the basis of a thorough, careful investigation in which the pros and cons of each possibility are weighed.

Each doctor and his family probably has some definite preferences about where to settle. Many times a physician wishes to return to his home town or set up practice in the community in which he took his internship or residency, since it may be easier to build a successful practice in an area where he and his family are known than in some new place. Or, he may have his eye on some particular "paradise" with climate appeal or other attractive recreational features.

The vital question for every doctor to consider is "Where can I build a successful practice and at the same time live a happy life?" The answer depends on an appraisal of the community and its practice-building possibilities as well as on the doctor and his family's own personalities and preferences. The young physician needs to ask questions like these:

Does the community need a physician? Can it support a physician? Can I find a good office location? Are hospital facilities available to me within a reasonable distance? Will I have access to diagnostic and therapeutic facilities? Are there drugstores in the area? Can I supplement my income with other work while building my practice?

And, equally important:

Will my family be happy here? Will we "fit in"? Can I find a suitable home? Are there churches, good schools, and stores nearby? Are there social and recreational outlets for us?

As a guide for physicians searching for an ideal location, the A. M. A.'s Council on Medical Service has published a leaflet, "Look Before You Leap," containing a checklist of considerations. It is available free on request and provides a good yardstick for measuring a possible location as a desirable place to live and practice.

Changing Population Trends

Aside from personal preferences about specific locations, a physician seeks a place where his practice will prosper. Changing patterns in population growth and in the delivery of medical care affect the economics of medicine today. With the development of new industries and the decentralization of old ones, there has been a great reshuffling of population with an exodus from cities to suburban areas. The development of modern cars and superhighways has speeded up this process so that distance no longer is a factor in obtaining speedy medical care.

Three things are of interest to a doctor searching for a location: the growth patterns of various areas, earning possibilities in these places, and the comparative need for doctors in relation to population. The West and Southwest, for example, are growing faster than other sections, and obvious growth would indicate a need for more doctors. However, it is important to find out if there is a real need or if a state already has enough doctors.

TABLE 1.—*Population per Active Physician*[*]

All United States	1,080	Montana	1,230
Alabama	1,660	Nebraska	1,110
Arizona	1,230	Nevada	1,230
Arkansas	1,420	New Hampshire	960
California	890	New Jersey	940
Colorado	910	New Mexico	1,600
Connecticut	830	New York	690
Delaware	1,090	North Carolina	1,620
Washington, D. C.	570	North Dakota	1,480
Florida	1,120	Ohio	1,140
Georgia	1,440	Oklahoma	1,220
Idaho	1,220	Oregon	1,050
Illinois	990	Pennsylvania	1,000
Indiana	1,200	Rhode Island	1,040
Iowa	1,250	South Carolina	1,750
Kansas	1,270	South Dakota	1,510
Kentucky	1,450	Tennessee	1,410
Louisiana	1,360	Texas	1,340
Maine	1,160	Utah	1,100
Maryland	1,110	Vermont	970
Massachusetts	830	Virginia	1,440
Michigan	1,400	Washington	1,220
Minnesota	1,250	West Virginia	1,490
Mississippi	1,720	Wisconsin	1,270
Missouri	1,160	Wyoming	1,340

---

[*] Excluding physicians in government services. Sources: U.S. Census Bureau; American Medical Directory, 1956 edition.

The current ratio of doctors to population is one index of an area's need for M.D.'s (table 1). However, some states suffer from a maldistribution of physicians, with an oversupply in such large cities as Los Angeles and New York.

The kind of doctor an area needs is important too. It might appear that a southern state was in need of obstetricians and pediatricians, yet, where people are in the habit of calling on midwives for such services, a doctor might have a hard time building a practice.

Doctors' incomes vary in different regions of the country, but so do living costs and taxes. A good doctor who selects his location wisely will always do well.

Because of the shifts to the suburbs, many young doctors are "decentralizing," too. New shopping centers, many offering attractive medical office space and ample parking facilities, add to the appeal. The doctor who specializes limits his choice to areas needing his particular kind of skill, or at least to areas not oversupplied with his specialty. Dependent on other doctor's referrals, he may lean toward practice in a large or medium-sized city. Yet some specialists are finding that by setting up groups they can do well even in comparatively rural areas. For the general practitioner, internist, obstetrician, and pediatrician, for example, the suburbs or rural areas offer the greatest opportunities for fast practice building. In table 2 are some things to consider in weighing the advantages and disadvantages of city, suburban, or rural practice locations.

TABLE 2.—*Pros and Cons of City, Suburban, and Rural Practice Locations*

Pro	Con
City	
Good hospital facilities	Oversupplied with physicians
Good diagnostic, therapeutic facilities	Practice-building slow
Availability of M. D.'s for consultation	Hard to get acquainted with patients
Medical centers with allied medical personnel, libraries, etc.	Requires 1 to 3 years to reach point where income meets expenses
Access to all cultural activities	Lack of parking facilities
Office space available, but costly	
Suburbs	
Usually good hospital facilities	May not be many hospital beds per doctor due to population increases
Usually access to diagnostic, therapeutic facilities	Area may be attracting many other M. D.'s, too
Usually M. D.'s available nearby for consultation	
[illegible] ple [illegible] her [illegible] ard: [illegible] for new doctors	
Many cultural activities; close to city for those not available locally	
Good schools, housing	
Office space available; parking ample	
Small Town or Rural Area	
Need for doctors to replace older men; often welcome new M. D.	Hospital facilities may be fewer, or some distance away
Practice may build fast; people may be anxious to help new doctor settle	Diagnostic, therapeutic facilities may not be easily accessible
Community may build office facilities equal to or better than those found in neighboring cities	May not be M. D.'s nearby for consultation
People generally "salt of the earth"	City-folk may find adjustment to rural life difficult
Doctor soon "belongs," feels needed	
Modern transportation measures miles in minutes to both cultural and hospital facilities	
Ideal place to raise children and to make friends	

Types of Practice

The doctor entering private practice not only must decide where he wants to practice, but how he wants to practice. Three possible choices are open to him: (1) open his own office, (2) become associated with a physician already established, or (3) associate himself with a group of doctors.

Each arrangement has its advantages and disadvantages, and the choice should depend on the individual physician's preferences, philosophy, and personality, though financial considerations sometimes enter the picture (table 3).

Opening Your Own Office.—The physician who opens his own office has the satisfaction of knowing that his success is entirely due to his own efforts, but he has the full responsibility for his patients and the operation of his practice. Such responsibility can become a great burden, cutting off a doctor from his family and depriving him of time for needed rest and vacations and for postgraduate education, but, for many, the rewards of "being your own boss" far outweigh these disadvantages. The man in solo practice must be a go-getter with plenty of stamina, for, in addition to caring for his patients, running the business side of his practice, and raising his family, he is called on as a leading citizen to shoulder his share of community responsibility. To set up his own office, he must have certain financial assets to carry him to the point where his practice pays. Financial aid is usually available from banks and other sources.

Working with Another Physician.—Many physicians whose practices have grown extremely large seek young men to help share the load. There are many advantages in such an arrangement for a new physician if the locality is good, their personalities compatible, and the agreement just. Such arrangements usually require little financial investment on the part of the young doctor, and he is soon busy with new patients. Often relationships of this type are extremely satisfactory, and the close association continues for years. At the outset the senior doctor looks on the younger man as an assistant, but in later years the relationship may change to that of associate or even partner. When difficulties occur, it generally results from personality differences, poorly thought out arrangements, or misunderstandings about the relationship. For this reason, a young doctor considering such an arrangement should be as certain as possible he can work harmoniously with the senior physician.

There are no ground-rules to determine what compensation a young doctor should receive when he goes into another physician's office. Compensation is determined by how much the new doctor is needed and the amount the senior doctor is willing and able to pay. The customary financial arrangement is one of a salary during a get-acquainted period with a promotion to associate at a later date with an adjustment of compensation more closely geared to the young doctor's individual effort.

Even though any agreement involves only two parties, it is wise to put it in the form of a clearly worded written contract, so that each doctor knows what to expect of the other. The length of time the physician is to remain on salary, the exact amount of salary, and the arrangements under which he will become an associate all should be clearly defined. The contract may have a "limiting practice" clause to protect the senior doctor. This clause prevents the new doctor from practicing within a certain distance from the senior doctor's office should the younger man withdraw from the agreement. It is wise to seek competent legal counsel when drawing up such a document.

Group Practice.—Since the end of World War II, group practice has been growing in the United States. Group practice is a collective effort on the part of four or more physicians to practice medicine. Net earnings of all physicians involved in the group are then apportioned between them according to some prearranged formula.

For example, a general practitioner, an obstetrician, a surgeon, an ophthalmologist, and a dermatologist might form a group, pooling any cash for outlay of equipment and establishment of an office. As their patient load grows, the group may seek a younger man to join them, with an opportunity to become a full-fledged member of the group at some later date.

To a young physician who likes to work with others there are some definite attractions in joining a group. First, there usually is no immediate investment of funds required. Second, the young doctor has access to all the diagnostic and therapeutic equipment and services he has been taught to use, and consultation with his associates is immediately available. Aside from professional considerations, group practice may afford more free time for study and recreation, since responsibility for continuous practice coverage can be shared by all members.

Not all physicians can adapt themselves to the "group first, individual second" approach necessary in a group arrangement. Furthermore, before joining a group the physician should become thoroughly acquainted with the whole subject of group practice and the various kinds of arrangements involved. Here are two suggested references: Could You Adapt Yourself to Group Practice? (Sedgwick, *M. Econ.* 33:128, 1956); Survey of Group Practice (Report of the Council on Medical Service, *J. A. M. A.* 164:1338-1348 [July 20] 1957).

Supplementing Practice Income

Many young physicians supplement their income during the time they are establishing their own practices by serving as industrial physicians or working for various health agencies, institutions, and schools on a part-time basis. Some perform insurance examinations for insurance companies; others get jobs as city physician, caring for police and fire department staff members. The possibilities for adding to income during early practice are worth investigating.

Placement Aids

Once a physician has narrowed down his preferences to the general area in which he wants to settle and has decided the type of practice he will enter, there are reliable sources which offer assistance:

Placement services of state medical societies, offering information about placement opportunities in each state.

Placement service of the American Medical Association, 535 N. Dearborn St., Chicago 10, supplementing state medical societies' service. Available to all physicians, regardless of A. M. A. membership.

TABLE 3.—*Net Earning by Type of Practice in Various Regions**

Type of Practice	West	Midwest	Southeast	Northeast	All U.S.
General practice	$16,044	$16,975	$14,550	$12,040	$14,817
Specialty practice	18,037	20,238	18,225	16,833	18,010
Solo practice	16,025	17,100	14,962	13,967	15,028
Two-man partnership ..	18,019	21,033	19,000	19,970	19,966
Larger partnership or group	22,006	21,958	22,025	16,000	21,460
All types of practice	17,035	18,037	16,026	14,039	16,017

* Source: Medical Economics' 8th Quadrennial Survey. Figures shown are 1955 medians for physicians who derive more than half their net earnings from fees for service (Reprinted from Riss, Inc. [Oradell, N.J.], by special permission. Copyrighted 1957).

Specialty group placement services, maintained by some specialty groups, such as the American Academy of Pediatrics and the American College of Radiology, for members.

Professional placement services, specializing in physician placement, working on a fee basis. Usually have numerous salaried or contract arrangements and hard-to-fill locations. Select a service in the section of the country in which you are interested. Addresses of reliable services available from the medical director of nearly every teaching hospital.

Classified columns of medical journals, medical publications often carry advertisements for physician locations.

Other physicians and detail men. Colleagues and pharmaceutical detail men often can be of help in advising of available locations.

"Moral" in selecting a location—get as much information as possible and weigh it all carefully before making any final decision.

MEDICAL FILM REVIEWS

No Time to Spare: 16 mm., color, sound, showing time 11 minutes. Produced in 1957 by Chetwynd Films, Ltd., Toronto, Canada, for the Life Insurance Companies of Canada. Procurable on rental ($12.50) or purchase ($125) from International Film Bureau, Inc., 57 East Jackson Blvd., Chicago 4.

This film emphasizes the importance of being prepared to use artificial respiration. Correct techniques are demonstrated in a variety of circumstances—the milkman who finds a woman unconscious on the kitchen floor, the wife who finds her husband unconscious in the garage, the passerby who finds a boy face down in a swimming pond. It points out that different applications of the back pressure, arm lift method are used on adults, young children, and infants. This film is a good presentation of the back pressure arm lift method of artificial respiration and emphasizes its usefulness in emergencies. It is dramatic and effective and also shows the necessity of medical follow up to the victim after the administration of artificial respiration. While it is designed primarily for lay audiences, it would be equally instructive to professional groups. Any group conducting a safety program for its members or employees will find this film a helpful teaching tool.

Assistive Devices for the Paralyzed Upper Extremity: 16 mm., color, sound, showing time 10 minutes. Produced in 1958 by and procurable on loan or purchase ($140) from William D. Loeser, M.D., 2183 Main St., Buffalo 14.

The purpose of this film is to demonstrate the assistive devices that are available for the patient with paralysis of both upper extremities. A wide variety of these devices are shown which meet the needs of patients whose disabilities range from mild weakness to extreme and total paralysis. Included in the film are an elementary aid for the shoulder with mild weakness, the flying saucer, counter-balance slings, full slings, tip feeder, ball-bearing feeder, especially devised equipment allowing use of muscles in another part of the body to produce motion of the hands and arms, and also motorized feeder equipment. This is an excellent film which is recommended for physiatrists, orthopedic surgeons, general practitioners, residents, interns, and physical therapists, and it could also be shown to patients with poliomyelitis.

The Human Machine: 16 mm., color, sound, showing time 14 minutes. Produced in 1955 by the Moody Institute of Science, Educational Film Division. Procurable on purchase (color $115, black and white $55) from Moody Institute of Science, 11425 Santa Monica Blvd., Los Angeles 25.

This excellent film compares the body's parts and operations with man-made machines. It explains how the parts of the body function together as interdependent systems. Included are animation, photomicroscopy, and x-ray to show how all of these systems are constantly at work so that the body machine as a living organism can adjust itself to the many internal and external changes which it experiences. It contains some extremely instructive original material from nature which gives it a permanent value. It is of general inspirational and educational value. It also brings out an important message regarding the respect with which the human body should be treated. Its greatest use would be in young peoples' groups and churches. It could also be used as a supplement in junior and senior high school classes and for physicians who are called on to address these groups.

Ergot, the Story of a Parasitic Fungus: 16 mm., color, sound, showing time 26 minutes. Produced in 1958 by the Wellcome Film Unit in collaboration with Sir Henry Dale and Prof. J. Chassar Moir, London. Procurable on loan from Burroughs Wellcome (U.S.A.) Inc., 1 Scarsdale Rd., Tuckahoe, N. Y.

A comprehensive review of the history and natural history of ergot, this film contrasts the poisonous and medicinal properties of the fungus. The life cycle is presented in detail and also included is the commercial handling of ergot in Portugal and a description of artificial methods of ergot propagation in Britain. The manufacturing methods which lead to the extraction of the alkaloids are shown, and there is a sequence depicting the discovery of ergometrine in 1935. The diagrams and photomicrographs depicting the various stages in the life cycle of ergot are well done, and the section on laboratory culture and artificial innoculation of the rye plant is informative. The sequence which illustrates the technique of extraction and separation of alkaloids is also good. The film as a whole is well made, and it is recommended for showing to pharmacists and students of pharmacy.

NEW FILM ADDED TO A. M. A. MOTION PICTURE LIBRARY

Urethral Catheters: 16 mm., color, sound, showing time 24 minutes. Presented by the Smart Family Foundation in cooperation with the American Medical Association and the American Hospital Association. Prepared by Samuel Fogelson, M.D., and Vincent J. O'Conor, M.D., Chicago. Produced in 1958 by Coronet Films, Chicago. Procurable on loan (service charge $1.00) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

The modern catheter and its uses, with accent on technique of preparation and usage, is depicted in contrast to the crude methods of ancient times. Emphasis is placed on the many and varied medical and surgical conditions in which the use of the urethral catheter plays so important a role. Hospital and operating room technique of having readily available sterile catheters is stressed. Considerable progress in the factory preparation of sterile catheter packaging has been made since the film was produced; however, this does not detract from the value of the film. Presentation of the historical background and demonstration of the type of catheter and technique of preparation of the catheter trays are good. This film is highly recommended for training of nurses, interns, and medical students.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Treatment of Protracted Septic Endocarditis with Antibiotics and Its Late Results. N. S. Chikina. Terapevtickeskiy Arkhiv 30:42-47 (No. 5) 1958 (In Russian) [Moscow].

Chikina reports on 230 patients with protracted septic endocarditis. One hundred thirty-three of these received small doses of antibiotics given in an irregular form. Seventy-six patients were treated with large doses of penicillin of from 1 to 2 million units daily and 35 of these were given penicillin and streptomycin. Of the total 74.4% presented a history of a preceding rheumatic disease of the heart. Three basic variants of the disease were observed: the septic, the cardiac, and the renal. The following results of the treatment of septic endocarditis with antibiotics were observed: (*a*) complete recovery with preservation of work capacity in the presence of valvular lesions well compensated; (*b*) practical recovery without return to work capacity, and in some of these cases a lethal result from 2 to 7 years later as result of cardiac insufficiency or as result of diffuse nephritis; (*c*) protracted course of the disease from 6 to 8 years with remissions lasting 1 to 2 years and with periodic exacerbation of the general septic phenomenon easily controlled by repeated course of treatment with antibiotics; (*d*) no effect on the disease with a lethal termination, most frequently with the development of acute circulatory failure and sometimes from secondary manifestations of sepsis. Favorable effects of antibiotics on the various clinical manifestations of the disease were manifested by improvement in the general state of the patient, diminution or total disappearance of general septic manifestations such as toxicity, lowering of the temperature, diminution in the size of the spleen, return to normal cardiac function and arterial pressure, and normalization of the blood. Histological studies demonstrated in the majority of the cases the presence of an ulcerative process on the heart valves despite the favorable therapeutic effect of the antibiotics on the various clinical manifestations of the disease. The best therapeutic effect of the antibiotics was noted in the septic variant of the course, particularly in the primary types of endocarditis without a preceding rheumatic fever; less favorable effect was noted in the cardiac clinical variant and least effect in the renal variant. A rapid development of circulatory failure in the course of the treatment was associated with acute perforation and deformation of the valves as a result of the reparative processes. Another unfavorable element was presented by myocardial changes as a result of the primary disease or of the preceding rheumatic cardiosclerosis. The best results were obtained by early treatment and systematic administration of large daily doses of antibiotics.

Clinical Experience with the SGO-Transaminase Test in Myocardial Infarction. M. A. Chapin. J. Maine M. A. 49:263-269 (July) 1958 [Brunswick].

The activity of serum glutamic oxalacetic transaminase (SGO-T) was followed for 2 to 6 days in the serums obtained from 54 patients with acute myocardial infarction who were admitted to the Central Maine General Hospital in Lewiston, Maine. The SGO-transaminase test was performed in an attempt to corroborate the clinical and electrocardiographic findings in these patients. The peak rise of the serum activity of the tested enzyme within 12 to 30 hours after the acute attack of myocardial infarction was 2 to 25 times the normal in 53 of the 54 patients. Serial electrocardiograms were abnormal but not diagnostic of the acute attack in 9 (16%) of the 54 patients with acute myocardial infarction. All of these had increased SGO-T activity reflecting the attack. SGO-T activity also was tested in 12 patients with angina pectoris, and in 17 patients with such other cardiac condition as coronary insufficiency, congestive heart failure, arrhythmias or acute pulmonary edema; the SGO-T activity was not elevated in these patients.

These results confirm those by other workers concerning the value of SGO-T determinations in the diagnosis of acute myocardial infarction. The SGO-T test should be used when there is a history of a previous myocardial damage, when heart block or arrhythmias are present, and when there is recurrent chest pain during convalescence from acute myocardial infarction; when the chest pain is atypical the SGO-T test should be performed as an aid in ruling out pulmonary infarction and various other cardiac, pulmonary, or acute upper abdominal conditions.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Prevention of Rheumatic Fever by Treatment of Streptococcal Infections: II. Factors Responsible for Failures. F. J. Catanzaro, Ch. H. Rammelkamp and R. Chamovitz. New England J. Med. 259:51-57 (July 10) 1958 [Boston].

The authors present a study on 5,198 patients examined during a 5-year period to determine the factors responsible for the development of rheumatic fever following therapy for a streptococcic infection. Only patients in whom Group A streptococci were present in the oropharynx at time of admission and who received treatment with one of the antibiotics or sulfadiazine were selected for this study. Of this group 76 patients had acute rheumatic fever and 46 (61%) showed the infective type during convalescence in contradistinction to the 20% infective type carrier rate in the total study population. An additional 16 (21%) of the 76 rheumatic patients showed a new type during convalescence as compared to 10% in the total treated group. In this study 9 (12%) of the total patients developed rheumatic fever within a few hours of the streptococcic infection. Other factors that may have accounted for some therapeutic failures were the acquisition of a new infection after therapy and, of less importance, a history of previous rheumatic attacks or recent streptococcic infections. Of the various methods employed, an injection of 600.000 to 1,200,000 units of benzathine penicillin not only is the least expensive but also requires only one injection and affords protection against reinfection or new infections for a period of three to six weeks. Oral forms of therapy may be employed but must be maintained for at least 8 to 10 days if the convalescent-carrier rate is to be reduced appreciably. Since the development of rheumatic fever after a streptococcic infection cannot be prevented in all cases by the treatment of such infections, the necessity for continuous prophylaxis in patients who have experienced one rheumatic attack should be emphasized.

Association of Functioning Carcinoid Syndrome and Scleroderma: I. Case Report. C. J. D. Zarafonetis, S. H. Lorber and S. M. Hanson. Am. J. M. Sc. 236:1-14 (July) 1958 [Philadelphia].

The authors present a 42-year-old woman who exhibited the classical signs of the carcinoid syndrome such as paroxysmal flushing of the skin, associated with telangiectasia, colicky abdominal pain and diarrhea, cardiac murmurs, and scleroderma-like changes of the lower extremities. Despite the fact that the diagnosis is obvious in retrospect, the correct diagnosis was not made while the patient lived. In addition to the typical clinical features of the carcinoid syndrome this woman presented 2 manifestations of unusual interest. One was the patient's history of extreme sensitivity to alcohol. Ingestion of only a small amount of alcohol was said to provoke generalized flushing and edema. This observation is not unique, having been noted previously in 4 other subjects with carcinoid tumors. The second unusual aspect was the extent of fibrosis. The fibrotic changes observed in the liver, inferior vena cava, and right heart are those classically associated with functioning carcinoid tumors. This has been emphasized from the time of the earliest case reports.

Carcinoidosis was established as the cause of death on autopsy, which revealed malignant carcinoid of the ileum with metastases to the liver, lungs, heart, breast, and appendix. Fibrotic changes were observed not only in the liver, inferior vena cava, and right heart but also in the skin of the legs, and in association with the tumor metastases. In view of the propensity of metastasized functioning carcinoid tumors to produce fibrotic changes in the right heart, it is surprising that little attention has been given to the possibility that similar changes might be induced elsewhere in the body. The authors cite several cases from the literature that are of interest as regards the extensive fibrosis, and point out that the woman presented also had extensive fibrotic changes. They also recall that a number of observers have postulated that the sclerosis of the valves of the right side of the heart is due to an excessive amount of serotonin produced in the hepatic metastases and released into the venous circulation. Failure to induce similar alterations on the left side of the heart appears to be due to the destruction of the serotonin by monoamine oxidase present in the lungs during the pulmonary phase of blood circulation.

Gastric Moniliasis (Candida albicans). R. G. Tinajero Ayala. Rev. med. Hosp. Gen. 21:269-293 (May) 1958 (In Spanish) [Mexico, D. F.].

Prolonged administration of antibiotics of any type may cause local and chronic or systemic and fatal Candida albicans infection. Gastric moniliasis from Candida albicans is extremely rare. The diagnosis is difficult. Only one case has been reported in the literature. The diagnosis was made during an autopsy. A woman 33 years old was hospitalized with a disease which had lasted for 3 months. The symptoms consisted of chills, headache, nausea, vomiting, dizziness, acute epigastric pain, weakness, marked loss of weight, melancholia, and periods of alternating constipation and diarrhea. The symptoms appeared at intervals of about 1 or 2 weeks, lasted for 3 or 5 days, and abated markedly, but they did not disappear entirely and after an interval they became aggravated. The treatment consisted of enemas, analgesics, Terramycin by mouth and intravenously, and penicillin. On hospitalization, it was observed that the cervical lymph nodes were enlarged and there was leukocytosis. A roentgenologic gastroduodenal examination showed what seemed to be a gastric neoplasm. A teleroentgenogram of the thorax showed that there were neither signs of bronchopulmonary disease nor pulmonary nor mediastinal metastases. Penicillin at daily doses of 1,000,000 units was given intramuscularly to the patient for 3 consecutive days. The treatment was discontinued when gastroscopy established a diagnosis of gastric moniliasis from Candida albicans. Repeated roentgenologic gastroduodenal examinations and gastroscopies were performed at intervals of weeks thereafter. The patient was on a proper diet with administration of vitamins. Biopsy during gastroscopy showed the presence of atrophic chronic gastritis. Candida albicans was identified from cultures of the gastric content taken during gastroscopy and also in cultures of material of gastric lavage given to the patient. Daily gastric lavages with lukewarm water with sodium bicarbonate were given to the patient for 3 consecutive weeks, at the end of which the patient had apparently recovered. She gained weight, the cervical lymph nodes became normal, and all symptoms disappeared. Repeated roentgenologic examinations of the gastroduodenal tract and repeated gastroscopies showed that the colonies of Candida albicans at first occupied the greater curvature of the stomach, from which they disappeared to reappear at the antropyloric region, from which they again disappeared to reappear at the fornix. The patient had become intolerant to sodium bicarbonate, and there was still Candida albicans in the material of a gastric lavage. Nystatin was given to the patient in daily doses of 500,000 units 3 times a day. Immediately the patient reported very ill with symptoms suggestive of gastritis and of gastric moniliasis. The roentgenologic gastroduodenal examination and gastroscopy showed a new colony of monilia at the antropyloric region. The final successful treatment consisted in administration of Amphotericin-B in daily dose of 4 Gm. for 15 days and of 6 Gm. for a few more days not specified by the author. Disappearance of the new colony of monilia from administration of amphotericin-B, was verified by roentgenologic examination of the gastroduodenal tract and by gastroscopy. The results, however, are too recent to justify definite conclusions.

Esophageal Hiatus Sliding Hernia: An Endoscopic Study. A. E. Dagradi, R. N. Killeen and R. Schindler. Gastroenterology 35:54-61 (July) 1958 [Baltimore].

The authors performed esophagoscopic and/or gastroscopic examinations on 106 men and 1 woman, between the ages of 20 and 79 years, with esophageal hiatus hernia of the sliding type. Esophagoscopy alone was performed on 26 patients, gastroscopy alone on 66, and both procedures on 15. Gastroscopy was complete in 72 patients, with both the subphrenic and supradiaphragmatic portions of the stomach being visualized. In 14 patients (19.4%) a normal sac and body were seen. Thirty-three patients (45.8%) showed abnormalities of the gastric mucosa limited to the hiatus hernial sac. The most frequently observed abnormality in this group was superficial and atrophic gastritis (15 cases each). Nine of these cases of gastritis were of the hemorrhagic type and explained the symptoms of hematemesis and/or melena. Three patients had hypertrophic gastritis. Transition was seen from superficial gastritis in the pouch to occasional atrophy in 2 patients undergoing multiple gastroscopic examinations over a period of several years. In 9 patients mucosal disease was seen in the body of the stomach, whereas the mucosa in the hiatus hernial sac was normal. The most common abnormality observed was superficial gastritis, which was found in 6 of the 9 patients. In 2 of them, it was the result of subtotal gastric resection (gastritis of the postoperative stomach). In 2 patients with Laënnec's cirrhosis associated with hiatus hernia varices were seen in the sac on gastroscopy, and in 1 patient a gastric diverticulum was seen in the pouch. In 16 patients (22.2%), mucosal disease was observed both in the main body and in the sac. Here again, the most common abnormality was atrophic gastritis (12 cases). In 2 patients of this group gastric ulcers were seen in the sac proper and were not shown on roentgenologic examination. In 1 patient a gastric ulcer of the lesser curvature was seen in the subphrenic portion of the stomach.

Of the 41 patients in whom esophagoscopy was accomplished, the esophageal mucosa was normal at the time of examination in 24, esophagitis was present in 9, and esophageal stricture with esophagitis was found in 4. In all of these patients the esophagitis was limited to the lowermost segment of the organ. The esophagoscopic method was less satisfactory for the detection of abnormalities of the mucosa in the herniated gastric pouch than was the gastroscopic method. The gastric mucosa was reported to be normal on esophagoscopic examination in 26 patients and was not seen in 4 patients in whom esophageal stricture prevented the instrument from entering the sac. Simple atrophic gastritis was present in 2 patients and superficial gastritis was observed in 9 patients. In this group active bleeding from the inflamed mucosa, together with erosions, was observed in 7 patients.

The frequency with which disease of the gastric mucosa has been found to be limited only to the herniated gastric pouch is noted. Gastritis of the superficial and atrophic types is the most commonly observed abnormality, and bleeding in association with gastritis frequently stems from erosion of the inflamed mucosa within the hiatus hernial sac. The reported data emphasize the clinical importance of endoscopy as an adjunctive procedure to radiography in patients with sliding esophageal hiatus hernia.

Results of Medical Treatment in Hiatus Hernia. C. A. Flood and G. C. Hennig. Gastroenterology 35:62-73 (July) 1958 [Baltimore].

The authors report on 52 men and 68 women, of the average age of 55 years, with roentgenologic evidence of hiatus hernia who had gastrointestinal symptoms the duration of which varied from a few days to 31 years. Twenty of the 120 patients also had a peptic ulcer which was located in the stomach or duodenum. The patients were given medical treatment which included a liberal bland diet of the type usually advised for the treatment of peptic ulcer, including feedings between meals. Alkalies and mild sedatives were prescribed after meals. The group of 100 patients with hiatus hernia without associated ulcer of the stomach or duodenum was observed for periods ranging from 6 months to 10 years. Thirteen of them were subjected to surgical treatment because of an unsatisfactory response to medical treatment.

The symptoms of hiatus hernia tended to be intermittent. During about one-half of the follow-up periods the patients were either free from symptoms or had, at most, mild bloating or heartburn which were readily relieved by appropriate medical treatment. Only 13 of the 100 patients had intractable distress with nocturnal heartburn or substernal pain which persisted for many months or years and could not be satisfactorily controlled by the usual therapeutic measures; 9 of these patients were finally operated on. There was no common factor in these patients with intractable symptoms which might explain the unfavorable clinical course. Inflammatory changes around the site of the hernia were revealed by the operation in 7 of the 9 patients; this perioesophagitis may well have played a part in the symptomatic picture in some of these patients. Moderate or severe symptoms occurred during about two-thirds of the follow-up periods in the 20 patients with hiatus hernia and associated ulcer of the stomach or duodenum. The results of medical treatment in the 18 patients who had at least one gross upper gastrointestinal hemorrhage and in the 10 patients in whom a stricture of the esophagus was observed showed no tendency for such patients to have persistent or frequently recurrent symptoms. The course of the disease in these patients was usually relatively benign; about one-half of the follow-up periods were attended by mild symptoms or absence of symptoms.

The results obtained in these patients with hiatus hernia suggest that the symptomatic course of the individual patient is the chief factor on which prognosis under medical management should be based. Prognosis was not necessarily related to such factors as duration of symptoms, the size of the hernia, or the demonstrability of gastroesophageal reflux on roentgenologic examination. Surgical intervention may be considered for those patients with continuing, rather severe symptoms which are not appreciably controlled by medical measures. It may be indicated in certain patients in whom multiple hemorrhages have occurred. Occasionally, patients with stricture of the esophagus may require surgical intervention if dilations cannot be carried out. Surgery may likewise become necessary in patients with hiatus hernia and ulcer of the duodenum or stomach. The reported data do not support the view that surgical intervention should be advised for patients with hiatus hernia as a prophylactic measure in order to avoid the complications of the disease.

Prognosis of Hodgkin's Disease. P. Croizat, P. Ponthus, J. Papillon and others. Presse méd. 66:1135-1138 (June 25) 1958 (In French) [Paris].

A statistical study of 110 patients with Hodgkin's disease observed and treated since 1939 by the same team of clinicians and radiotherapists has revealed certain important elements that have a bearing on the prognosis and course of the disease. These elements are of 3 kinds: those relating to the clinical and biological syndrome; those relating to the patient; and those relating to the treatment. The duration of the average survival in these patients (41.8 months from the initial treatment, not from the onset of the disease) has only a limited value because it links the 68 who died and whose survival time was accurately known but relatively short with the 42 who are still alive and whose survival time has been artificially set at a level below the fact. A more reliable criterion is provided by the duration of the first remission, that is, the period between the initial treatment and the first relapse. This period of symptomatic equilibrium has an undeniable prognostic value and indicates the patient's future. Division of the patients into 3 groups—60 who relapsed during the 1st year, 21 who relapsed between the 1st and 2nd years, and 24 who passed the 2nd year without a relapse—showed that the average survival in the 1st group was 28.5 months; in the 2nd group, 56.6 months; and in the 3rd group, 63.9 months. This criterion is equally valid in relation to the late results, so that patients who have not relapsed by the end of 2 years may be regarded as having 1 chance in 2 of surviving for 5 years or more.

Clinical and biological elements with an adverse effect on the prognosis are diffusion (Peters' stage 3), enlargement of the spleen, involvement of the prevertebral lymph nodes, fever and impairment of the general condition, and anemia. Consideration should also be given to the character of the swollen lymph nodes. Those that are fibrous and low in radiosensitivity from the beginning are certainly less favorable than those with a soft consistency, an abundance of Sternberg cells, and high radiosensitivity. Hodgkin's disease is admittedly more severe in men than in women, and this characteristic, which is undoubtedly linked to hormonal conditions, was evident in these patients. The average survival time for men was 36.2 months as against 46.7 months for women, and the average length of the first remission was 14.1 months as against 23.3 months.

Analysis of the effect of therapy on prognosis indicates that the duration of the first remission is clearly dependent on the kind of treatment given. Too few patients were treated surgically to permit any definite conclusions, but prolonged remissions were secured in 3 of the 6 who were operated on. The disease in all 6 patients, however, was localized and limited to a single lymphatic territory. Radiotherapy, when started as soon as possible and given intensively enough to sterilize the irradiated territory, with the not inconsiderable help of chemotherapy (nitrogen mustard), is undoubtedly responsible for durable remissions and a prolongation of the survival time, which amounted in 6 patients to 10 years and in 3 to more than 12 years—a period of remission long enough to be regarded as equivalent to a cure.

Intrinsic-Factor-Inhibiting Substance in Serum of Orally Treated Patients with Pernicious Anaemia. M. Schwartz. Lancet 2:61-62 (July 12) 1958 [London].

The author studied serums from healthy persons and from orally treated patients with pernicious anemia for the presence of antibody against intrinsic factor, pointing out that pernicious anemia has been treated with intrinsic factor for more than 25 years, especially in the Scandinavian countries. Hog pyloric mucosa causes substantial absorption of vitamin B_{12} in pernicious anemia, and such preparations administered initially almost always produce complete remission, but in prolonged treatment with preparations of this type a considerable proportion of the patients relapse, and several have shown myelopathy. The cause of the failure is a block in the intestinal absorption of vitamin B_{12} with hog pyloric mucosa as intrinsic factor; the block is not present when homologous intrinsic factor is administered. The block may be due to some sort of sensitization. Recently an antibody to Castle's intrinsic factor was reported by Taylor and Morton. They immunized rabbits with intrinsic factor preparations from man and from pig pylorus and found in the serum of the treated rabbits a substance inhibiting human and pig intrinsic factor respectively. The authors used Schilling's urinary excretion test. Vitamin B_{12} labeled with Cobalt 60 (Co^{60}) was administered by mouth, and 2 hours later unlabeled vitamin B_{12} was given intramuscularly.

Studies were made on serum from healthy persons and from 4 groups of patients: (1) untreated pernicious anemia patients; (2) those in whom pernicious anemia had been treated for from 1 to 5 years with oral preparations of vitamin B_{12} plus hog pyloric mucosa; (3) pernicious anemia patients treated orally with a crude stomach preparation; (4) pernicious anemia patients treated by injection. Intrinsic-factor-inhibiting activity was found in a considerable proportion of serums from patients with pernicious anemia treated orally. Serum from healthy persons and patients with untreated pernicious anemia contained no such activity. As intestinal absorption of vitamin B_{12} proved to be normal in some patients with inhibiting activity in the serum, and as the intrinsic-factor-inhibiting activity was shown to operate also against human intrinsic factor, such activity is probably not the sole cause of the intestinal blockade following long-continued oral treatment of pernicious anemia.

Behçet's Syndrome or Touraine's Aphthosis. P. Thibault. Presse méd. 66:1000-1001 (June 4) 1958 (In French) [Paris].

Behçet's syndrome, in which 3 components—recurrent iritis, hypopyon, and mucosal aphthae—are associated, is the best known but not the most frequent manifestation of Touraine's aphthosis, a complex general disease of infectious (probably viral) origin. The basic elements invariably present in aphthosis are buccal and genital aphthae, alone or in small numbers, which give rise to burning and itching and which may lead to inflammatory reactions in the affected tissues. Spontaneous recovery is characteristic of the disease, but recurrences are common and may occur at intervals for 20 years. Nonaphthous manifestations, which appear chiefly in severe forms of the disease, may be cutaneous, ocular, articular, visceral, vascular, general, or nervous. Ocular manifestations, which form part of Behçet's syndrome, were found by Touraine in 62 of 148 patients with aphthosis. Conjunctivitis, alone or in association with iritis, is transitory but may recur with the aphthae. Keratitis, too, is often recurrent. Iritis, alone or with hypopyon, which may be unilateral at first but generally becomes bilateral, is a serious complication because when it is recurrent the iridocyclitis or total uveitis by which it is often accompanied may lead to synechiae, atrophy of the ciliary body, and a greater or lesser loss of visual acuity that may become permanent and definitive.

Less well known manifestations of the disease are those affecting the nervous system. Some consist of extrapyramidal disturbances that may suggest those of multiple sclerosis. Others take the form of paresis of the legs with urinary disturbances, quadriplegia, or monoparesis for which the patient is forced to seek advice. The prognosis in Touraine's aphthosis, which is usually benign so far as life is concerned, becomes somber in patients with neurological manifestations. Severe cases run a fatal course in spite of the use of cortisone, either alone or in association with antibiotics. The suggestion has been made that the infection reaches the brain from the eye, traveling along the optic nerve, but the fact that ocular lesions were lacking in 3 of 18 cases with neurological complications reported in the literature is a serious objection to this theory. Some authors have proposed replacement of the term Behçet's syndrome by the term Behçet's disease, because the neurological manifestations constitute a 4th element in addition to the standard 3. The absence of ocular lesions in some cases, however, makes it seem better to regard the condition as a part of the major syndrome of aphthosis described by Touraine.

Pathergic Granulomatosis (Wegener's Granuloma) of the Lung: Five Cases of Similar Clinical Courses and Pathologic Findings. R. M. Hood, H. V. O'Connell and D. L. McCord. Am. Rev. Tuberc. 78:21-37 (July) 1958 [New York].

The author's report on 3 men and 2 women between the ages of 19 and 35 years, whose chest roentgenograms showed diffuse, fine, nodular, pulmonary infiltration throughout both lung fields. Three patients were asymptomatic during the entire 4-year period of observation. One woman had complaints of malaise, fever, and weight loss for 4 months before admission to hospital; this patient became asymptomatic while under observation and without any specific therapy. Biopsy of the lung was performed and revealed granulomatous lesions associated with tissue eosinophilia and angiitis in all 5 patients. Despite the angiitis, necrosis was not a prominent feature. The inflammatory reaction within the vessel walls was characterized by polymorphonuclear and round-cell infiltration in all layers. Endothelial proliferation was present in some but not in all. The bulk of the granulomatous masses was composed of aggregates of epitheloid cells, macrophages, lymphocytes, plasma cells, and myriads of eosinophils. The surrounding lung parenchyma not involved in the granulomatous process showed some alveolar distortion and compensatory emphysema. Four patients showed no clinical or laboratory evidence of involvement by a granulomatous process of the upper respiratory passages, kidneys, the vascular system outside the lung, or of any other organ system. The remaining patient was the only exception, having in addition a solitary rib lesion histologically typical of eosinophilic granuloma. None of these 5 patients has had symptoms, physical signs, or laboratory findings of allergic disease states, nor did any of them show peripheral eosinophilia.

Similar findings have been reported in the literature under various names and by many workers. Histologically, the cases of the 5 patients were strikingly similar to those reported as Wegener's granulomatosis of the lung but their clinical courses were benign. Pathologically the various lesions did not differ sufficiently in the patients to require that, because of various clinical findings and courses, their diseases be considered as unrelated diseases of different causation. The term "pathergic granulomatosis" suggested by Fienberg who defines the word "pathergy" as "the totality of morbid phenomena which can be produced by a state of altered tissue reactivity," is recommended by the authors for general use until the causation of this group of diseases is clarified. Fienberg suggested the division of the diseases into 2 groups, the first of which is comprised of patients having widespread lesions or multiple organ involvement and the second group consisting of those in whom the lesions are confined to a single organ or organ system. Four of the 5 patients belonged to the second group, and 1 to the first group. The diagnostic value of lung biopsy has again been demonstrated.

Gas in the Pancreas as a Sign of Abscess. J. W. Agnos and R. B. Holmes. Am. J. Roentgenol. 80:60-66 (July) 1958 [Springfield, Ill.].

Two patients with a gas-containing pancreatic abscess are presented. The patients were women, aged 70 and 44 respectively. The elderly woman was investigated because of an upper gastrointestinal hemorrhage and symptoms suggestive of a peptic ulcer. Roentgenography of the abdomen showed an extensive gas-containing cavity occupying the greater portion of the left upper quadrant and displacing the gas-filled stomach to the right and the splenic flexure inferiorly. Just to the left of the spine, superimposed on the gas shadow of the stomach, was a small cluster of radiolucencies. A diagnosis of pancreatitis and subphrenic abscess was made on the basis of the roentgenologic findings. A small incision was made just below the left costal margin. Fluid and air gushed out through the incision and 1,500 cc. of serosanguineous, foul-smelling fluid was aspirated. The findings confirmed the roentgenologic impression of a mass associated with the pancreas. An empyema in the left pleural space was drained 2 weeks later. The cluster of radiolucencies, seen on admission, was still present but reduced in size 6 weeks later. One month later, a left paramedian incision was made over the mass in the abdomen. A drainage tube was inserted. The clinical course was downhill and the patient died 1 week after the final operation.

In the second patient a plain roentgenogram of the abdomen showed a collection of small radiolucencies, up to 0.8 cm. in diameter, located to the right of the spine, extending to the lower lumbar region, and covering an area 9 by 10 cm. At operation a mass was found in the mesocolon in front of the duodenum and pancreas. There was fat necrosis and the pancreas contained calcific plaques in the tail and body. The mass was incised and a quantity of gray-yellow purulent material was evacuated, together with large pieces of necrotic pancreatic material. The pathological diagnosis was pancreatitis with fat necrosis and pseudocyst. Postoperatively, a gastrointestinal series showed a deformed duodenal cap. In an addendum the authors state that 3 additional patients with gas-containing pancreatic abscess were observed since the preparation of this paper. Of the total of 5 cases, 4 showed collections of gas bubbles on the roentgenograms (1 showed a single cavity with irregular walls); 3 were fatal. The contention that an abscess or pseudocyst complicating pancreatitis can be predicted from a persistently elevated serum amylase level is unfounded, since in 2 cases in which serial amylase determinations were carried out, the levels were normal. Abscesses of the pancreas may occur in association with acute pancreatitis or may follow an exacerbation of chronic pancreatitis. Surprisingly, they are very rare as a complication of a penetrating peptic ulcer.

Hyperthyroidism. I. W. Rose Jr. North Carolina M. J. 19:255-258 (July) 1958 [Winston-Salem].

Laboratory investigation of hyperthyroid conditions is dependent generally on the assessment of the basal metabolic rate, measurement of the precipitable or protein-bound iodine, and the utilization of radioactive iodine (I^{131}) techniques. One of the latter procedures involves the measurement of the amount of iodine which is taken up as compared to either the total dose or the speed with which it is taken up. Another method is the I^{131} release test which determines the rate at which the labeled hormone is released from the gland. Localization techniques are possible in the event of discrete nodules. Surgery, the use of antithyroid drugs, roentgenologic therapy, and I^{131} therapy are the 4 modes of treatment in common usage today. Treatment with I^{131} is indicated in persistent or recurrent exophthalmic goiter following surgery, in exophthalmic goiter in persons past the age of 40, in the patient who refuses or is refused surgery on the basis of medical or emotional conditions, and in the patient with malignant exophthalmos. I^{131} is contraindicated in the exophthalmic goiter patient under 40, in patients with toxic nodular goiter, in patients with very large toxic goiter, in pregnant women, and in the severely hyperthyroid patient. Although attention has been directed largely toward laboratory procedures and methods and conditions for treatment, laboratory procedures, as such, are merely adjuncts to astute clinical evaluation, the selection of treatment on an individual basis being considered far better than any rules that can be laid down.

Antibiotic-Resistant Staphylococcal Outbreaks in a Medical and a Surgical Ward. M. Barber and A. A. C. Dutton. Lancet 2:64-68 (July 12) 1958 [London].

Two outbreaks of staphylococcic infection in hospital wards are reported. The first outbreak was in a male medical ward, the second in a male surgical ward. Each outbreak was due to the admission of a patient with superficial staphylococcic infection. In both outbreaks the offending staphylococcus was resistant to erythromycin as well as to penicillin, streptomycin, and tetracycline, and in 1 outbreak the erythromycin resistance followed treatment of the initial patient with this antibiotic. In the medical ward, although the bedding of 7 patients in widely scattered areas of the ward was infected, there were no cases of severe sepsis. After the infected patients had been discharged and all the blankets and ward curtains had been superseded by fabrics treated with a quaternary ammonium compound, the epidemic strain was no longer found. In the surgical ward a single strain of Staph. pyogenes of phage type 80 caused severe infections (of which 1 was fatal) in 8 patients, 2 nurses, and 1 surgeon. The offending strain was only eliminated by closing the ward and by spraying with cetrimide (a quaternary ammonium antiseptic).

Comparative Severity of Atherosclerosis in Costa Rica, Guatemala and New Orleans. C. Tejada, I. Gore, J. P. Strong and H. C. McGill Jr. Circulation 18:92-97 (July) 1958 [New York].

The authors' study is concerned with the comparative severity of aortic atherosclerosis in low-income Costa Ricans, Guatemalans, and New Orleans whites, which was studied in 941 aortas obtained from autopsies. No significant differences were observed in the 4 grades of atherosclerosis in the 3 countries before the age of 30. The size and extent of the lesions increased progressively with age in patients over 30; the increase was most rapid in New Orleans and least rapid in Guatemala. Racial factors are unlikely to be responsible, therefore, environmental factors might account for these differences, of which diet appears to be one of the most important. The dietary habits, serum cholesterol levels, and lipoprotein levels were compared with the pathological findings in the patients of the 3 countries. There is an apparent correlation between the dietary fat intake, the serum cholesterol levels, S_f 0-12 lipoprotein fraction, and the degree of aortic atherosclerotic lesions as measured by these methods.

Pleural Biopsy in Diagnosis of Effusions: Results in 50 Cases of Pleural Disease Observed Consecutively. H. E. Hill, N. M. Hensler and I. A. Breckler. Am. Rev. Tuberc. 78:8-16 (July) 1958 [New York].

Biopsy specimens of the pleura were obtained from 42 male and 8 female patients, between the ages of 2 and 48 years, with pleural effusion or thickened pleura. Of the 50 consecutive patients, 32 had pleural disease which was considered to be of tuberculous origin. Biopsy tissue was histologically and/or bacteriologically diagnostic in 19 (59%) of the 32 patients. With other methods, exclusive of pleural biopsy, the tuberculous origin of the pleural disease was established in only 11 patients (34%). Of 18 patients with pleural effusion of nontuberculous origin, pleural biopsy was diagnostic in 1 patient, helpful in another, and noncontributory in 16. Pleural biopsy by open biopsy techniques with the aid of local anesthesia is a simple and safe procedure. It has proved to be a valuable addition to the traditional diagnostic techniques in pleural disease of tuberculous origin, materially increasing the number of definite diagnoses obtained. The finding of nonspecific inflammation or noninflammatory tissue cannot be used to exclude the presence of tuberculosis. The technique may be of value in occasionally establishing a diagnosis of neoplasm or nontuberculous inflammatory disease.

Pleuritis in Systemic Lupus Erythematosus: Its Importance as an Early Manifestation in Diagnosis. W. A. Winslow, L. N. Ploss and B. Loitman. Ann. Int. Med. 49:70-88 (July) 1958 [Lancaster, Pa.].

Pleuritis, with and without effusion, was found in 41 of 57 patients from whom chest roentgenograms were available for study and in whom the diagnosis of systemic lupus erythematosus was established beyond reasonable doubt either during life or by autopsy. Certain criteria were used for the diagnosis during life which appeared to be justified by the findings in 23 of the 24 patients in whom the diagnosis was established by autopsy. Pleuritis was recorded in 10 of 20 additional patients with systemic lupus erythematosus from whom chest roentgenograms were unobtainable. Pleuritis appeared as an isolated first sign in 3 of the 57 patients; it appeared with few antecedent symptoms of systemic lupus erythematosus in 16 additional patients. Despite this high incidence of early pleuritis in patients with systemic lupus erythematosus, a review of the literature showed that sufficient weight was rarely given this disease in the differential diagnosis of "idiopathic pleuritis."

By far the most striking symptoms of systemic lupus erythematosus which preceded pleuritis was arthritis or arthralgia. The manifestations of systemic lupus erythematosus coinciding with pleuritis were pericarditis and pneumonitis, but with a lower incidence than had been noted by other workers. Pleuritis was followed by complete clearing in 14 of the 39 patients with uncomplicated disease who were followed by chest roentgenograms, and in 8 pleuritis cleared save for minimal pleural residua. Survival after the first pleuritic attack averaged 39.9 months, with 23 of the 41 patients still alive at last follow-up. Bilateral pleuritis, either simultaneous or alternating, was observed in 23 patients, and in 13 of the remaining patients the pleuritis was left-sided. Despite the tendency to frequent infections in patients with systemic lupus erythematosus, it was possible to rule out infectious, neoplastic, and metabolic causes of the pleuritis in most patients. In view of the increasingly favorable results of treatment in patients with systemic lupus erythematosus, not only symptomatically but also in objective prolongation of life, the prompt study of cases of unexplained pleuritis is urged for systemic lupus erythematosus as well as for tuberculosis or neoplasm.

SURGERY

Direct Vision Correction of Mitral Insufficiency. E. B. Kay, C. Nogueira and H. A. Zimmerman. Surgery 44:325-332 (Aug.) 1958 [St. Louis].

The authors report on 17 patients, between the ages of 19 and 51 years, with disease of the mitral valve who were operated on at the St. Vincent Charity Hospital in Cleveland, Ohio, with use of a rotating disk-type oxygenator for total cardiopulmonary bypass and direct vision correction of the valvular defect. Thirteen patients were operated on for mitral regurgitation and 4 for mitral stenosis. A left-sided exposure was used in 4 patients and a right-sided exposure in 13. After the exposure the various anatomic, pathological, and physiological aspects of the mitral valve were determined by digital examination before opening the auricle in an attempt to assess the various contributing factors and to formulate the plan of attack. A variety of annular plication was used in correction of mitral regurgitation. Multiple point plication was employed primarily in patients with pure mitral regurgitation. Medial annular plication was used in patients with "tear drop" deformity. Bilateral annular plication was used primarily in patients with "patulous" deformity. Occasionally an Ivalon plug was used to prevent overlapping of valve cusps. Elective cardiac arrest was employed in 8 patients; 4 of them had ventricular fibrillation which was treated by electric shock. The duration of the cardiac arrest varied from 15 to 35 minutes.

There was spontaneous resumption of the normal heart beat in the other patients. There were no arrhythmias in the 9 patients in whom intermittent aortic occlusion was employed, even though the occlusion lasted as long as 4 to 5 minutes in some of the patients.

There was 1 operative death which occurred in the first patient to be operated on. The lungs were congested, and other evidence of cardiac failure was present, including pleural fluid, an enlarged liver, and peripheral edema. The operation was long and a blood imbalance was present at the end of the procedure which, in combination with a prolonged cardiac arrest of 35 minutes and myocardial insufficiency, contributed to this failure. Of the 4 patients who were operated on by the left-sided approach with use of cardiac arrest, 1 had a poor result and another had only a fair result. In retrospect it is felt that with the heart stopped it was impossible to evaluate properly the residual insufficiency and to take the necessary steps to correct it. The other patients have all done well for periods of 2 to 8 months. It is still too early for a long-range evaluation. With the use of a mechanical pump-oxygenator, direct vision correction of mitral regurgitation will now be a realization. It is felt that the right-sided approach to the mitral valve allowing the heart to beat during the surgical correction, but with intermittent aortic occlusion, will be associated with the greatest number of successful results. The surgeon must, however, be able to vary his operative technique to best cope with the individual problems presented in each patient. The operative mortality and morbidity are extremely low. Definite factors in this morbidity and mortality are the myocardial insufficiency and pulmonary vascular disease present in the patient with far-advanced mitral insufficiency. Operative intervention should be employed before irreparable damage occurs.

Cancer of Tongue: 100 Cases. V. E. Argonz. An. Cir. 23:35-39 (Jan.-March) 1958 (In Spanish) [Rosario, Argentina].

One hundred patients with cancer of the tongue were observed at the Tumor Institute of Rosario, Argentina, between 1944 and 1954. Most of the patients were between the ages of 50 and 70 years. Eighty-three were men and 17 were women. The tests for syphilis gave positive results in 16 patients. The cancer was located at the base (root) of the tongue in 42 cases; it involved the three thirds of the movable part of the tongue in 5 cases and 1 or 2 thirds of the movable part of the tongue in 43 cases. In the remaining 10 cases the cancer was located either at the lateral edges or at the ventral surface of the tongue. The tumor was Basal cell epithelioma in 93 cases, carcinoma in situ 1, hemangioendothelioma in 1, tumor of the mixed glandular and mucous type in 1, carcinoma with reticular cells in 3, and fibrosarcoma in 1. The basal cell epithelioma was of the second or third degree of cellular differentiation in almost all cases. Cervical metastases showed on hospitalization in 65 patients; they developed in the course of the treatment in 6 patients, and did not appear at all in 29 patients. Fourteen patients were already at the inoperable stage of the disease. They were not given any treatment, not even palliative. In the remaining 86 patients, the treatment consisted of roentgenotherapy to 30 patients, radium to 15, surgical removal of the cancer lesion from the tongue in 3, combined roentgen and surgical treatment in 9, and radium combined with surgery in 29 patients. Metastases at a distance appeared in 9 patients in the course of the treatment. They were generally located in the liver, lung, or cervical vertebrae, but in some cases the metastases appeared in the form of diffuse carcinoma. They were the immediate cause of death in all patients. Forty-nine patients (including the 14 patients who were in the inoperable stage of the disease) died within 1 year after hospitalization; 30 patients are living without any recurrence or residual lesion. Fifteen of these patients had lived between 1 and less than 5 years, and the other 15 patients had lived for more than 5 years. One patient is living with local metastases 15 months after surgical removal of half of the tongue. The author concludes that cancer of the tongue is almost as frequent as cancer of the lips or of the larynx, and that the prognosis is very poor. The treatment should be conducted as follows: Interstitial radium when the lesions are located at the movable part of the tongue, teletherapy when the lesion is at the root of the tongue, and radical dissection when there is cervical adenopathy. Cervical adenopathies should not be dissected early but only when they are clinically demonstrable. Dissection in block is indicated when the primary tumor cannot be controlled, as shown by results of histological examinations.

Oophorectomy in Breast Cancer: An Attempt to Correlate Results with Oestrogen Production. R. D. Bulbrook, F. C. Greenwood, G. J. Hadfield and E. F. Scowen. Brit. M. J. 2:7-11 (July 5) 1958 [London].

The first of 2 groups studied had been oophorectomized prior to the initiation of this investigation and no preoperative estrogen levels were available. In the second group both preoperative and postoperative estrogen determinations were made. Four premenopausal patients who had shown a history of regular menstruation were studied after oophorectomy. The results indicate that oophorectomy in premenopausal women removes a major source of estrogen production, however adrenal secretion of estrogen is always detectable after operation and can vary within wide limits, and would possibly afford a rational explanation for the clinical failure in the 2 patients who died 7 months postoperatively. Remission of the disease process was obtained in 2 of the 4 patients although estrogen was always detectable in the urine. The preoperative estrogen levels in the menopausal (menstruated within the last year prior to operation) group are low compared with those found in premenopausal women and suggest that an ovarian contribution in the menopausal group was lacking prior to operation. The immediate effects of oophorectomy on estrogen secretion would appear to be determined by the degree of operative stress and the individual reaction to such stress. In 1 patient the level increased for 1 month postoperatively and the course of the disease was not affected; in another instance the excretion fell to zero only to increase with the progression of the disease; and in the 2 other cases the immediate effects were not maintained. The overall effect of oophorectomy in the postmenopausal group is that both the clinical course of the disease and the estrogen level remain unaltered. Estrogen derived from the adrenal glands appears to be present in all patients following oophorectomy. The removal of this source of production by further endocrine surgery is indicated when oophorectomy fails to arrest the progress of the disease.

Adrenalectomy in Breast Cancer: An Attempt to Correlate Clinical Results with Oestrogen Production. R. D. Bulbrook, F. C. Greenwood, G. J. Hadfield and E. F. Scowen. Brit. M. J. 2:12-15 (July 5) 1958 [London].

Continued excretion of estrogen produced by the adrenal cortex occurs after oophorectomy in the majority of women with breast cancer. When adrenalectomy fails to induce a growth regression in breast cancer estrogen independence is assumed. Of the 13 patients studied only 3 were in remission at the time that estrogen estimations were carried out. In the first case regression of the tumor was associated with the virtual disappearance of estrogen from the urine. In the second case, which illustrated the transition from regression to relapse, estrogen excretion was persistent during regression, rising considerably during relapse until shortly before death. The third case, which likewise demonstrated the transition from relapse to remission, did not demonstrate an accompanying rise in estrogen excretion. Of the remaining 10 cases described in this series, 5 patients either derived no benefit from adrenalectomy or, when the estrogen estimations were carried out, were in relapse and not excreting detectable amounts, while the other 5 patients were excreting estrogen while the disease was progressing. Bilateral adrenalectomy caused a marked reduction in the amount of estrogen excreted, but complete abolition of excretion was not always achieved. Continued estrogen excretion did not preclude objective regression, and conversely progression of the disease process did occur in spite of the fact that no estrogen could be detected in the urine.

Hypophysectomy in Breast Cancer: An Attempt to Correlate Clinical Results with Estrogen Production. R. D. Bulbrook, F. C. Greenwood, G. J. Hadfield and E. F. Scowen. Brit. M. J. 2:15-18 (July 5) 1958 [London].

The beneficial effects of hypophysectomy as an effective means of palliation in a significant proportion of cases of metastatic breast cancer have been ascribed to the inhibition of ovarian and adrenal function due to the removal of the relevant pituitary trophic hormones and to the removal of those pituitary hormones which might have a direct influence on breast cancer. In the 16 patients studied estrogen determinations were carried out both preoperatively and postoperatively. Of the 11 patients who obtained regression following hypophysectomy 4 had been previously treated by oophorectomy, 5 were postmenopausal, and 2 had undergone both adrenalectomy and oophorectomy. The anticipated effect of hypophysectomy is reduction or abolishment of estrogen excretion, and this was found to be true in this series for women past the menopause or those in remission following oophorectomy. In 7 of the 9 patients in the latter category no estrogen could be detected after the first postoperative month. In 2 instances in this same group estrogen was detected preoperatively. In 2 of the 11 patients obtaining remission following hypophysectomy estrogen was detected in the urine postoperatively. Four women comprised that group of patients which did not benefit by hypophysectomy. All had previously been treated by mastectomy; 3 had undergone subsequent oophorectomy; and the fourth had not menstruated for a year following a course of testosterone treatment. At the time of operation all of the patients showed evidence of skeletal metastases which were unaffected by hypophysectomy. The average survival time was 8 months. In no cases was estrogen excretion abolished or reduced by operation. The last of 16 cases was a male who suffered from widespread metastases which were not altered by either orchidectomy or subsequent hypophysectomy, the latter operation reducing but not abolishing estrogen secretion. Patients deriving no benefit, generally, tended to have a high preoperative estrogen excretion, and continued to excrete estrogen after operation.

The Effect of Hypophysectomy in Advanced Carcinoma of the Breast. D. N. Baron, K. J. Gurling and E. J. R. Smith. Brit. J. Surg. 45:593-606 (May) 1958 [Bristol, England].

The authors report on 57 women, between the ages of 24 and 69 years, who were admitted to the Royal Free Hospital in London with advanced cancer of the breast. Fifty-two of these underwent surgical hypophysectomy, 2 had pituitary stalk section alone, and 3 had radioactive seeds inserted by the nasal route. Previous treatment had included radical mastectomy in 39 patients, local mastectomy in 4, irradiation therapy in 44, and adrenalectomy in 5. Of the 52 patients subjected to surgical hypophysectomy, 17 (33%) were in the premenopausal stage, 21 (40%) were in the postmenopausal stage, and 14 (27%) had undergone either surgical or irradiation castration. Surgical hypophysectomy with the insertion of 5 unscreened radioactive gold seeds (Au^{198}) is considered the best method of pituitary ablation. The seeds are placed deep in the fossa, 1.5 cm. below the optic pathways, and kept in place with fibrin plaques above and below; they emit beta particles and gamma rays. A higher proportion of women in the premenopausal stage improved after hypophysectomy than was the case in the postmenopausal group. There were 7 operative deaths among the 52 women undergoing this operation; death resulted from cerebral hemorrhage in 4, from extensive cerebral softening apparently due to venous thrombosis in 2, and from pulmonary edema in 1. Two patients died within the first postoperative month, 1 of pulmonary insufficiency due to irradiation fibrosis, and the other of increasing cachexia. Of 33 who survived the operation for 3 months or more, 22, i. e., 42% of the 52 patients, showed objective evidence of improvement with regression of the growth in 15, and with arrest of the growth in 7. Subjective improvement including relief of pain, increase in appetite, and increased feeling of well-being occurred in 25 of the 33 patients. The average duration of remissions was 8.1 months, the longest being 27 months, and 12 patients are still alive. Eleven of the 33 patients showed no improvement. There appeared to be a prolongation of life from an average of 3.2 months for patients showing no response to an average of 10.1 months in those showing improvement.

The pituitary fossa was examined at autopsy in 17 patients, and an attempt was made to make a rough estimate of the volume of anterior lobe-tissue remaining. Results showed that total ablation of all anterior pituitary tissue is rarely possible, but clinical improvement was observed with between 10 and 20% of tissue in the fossa. There was little evidence of regrowth of the pituitary stalk or of the parenchyma of the gland. The results of postoperative tests of pituitary function have been reviewed and correlated with the findings on postmortem examination of the pituitary fossa. Hypophysectomy is an effective method of palliating advanced metastatic cancer of the breast and it is preferable to adrenalectomy, but it should not be considered a routine procedure. Hypophysectomy may contribute materially to the elucidation of cancer metabolism and hormone dependence. The search for new methods of treatment must continue.

Emergency Portacaval Shunt. W. P. Mikkelsen and A. C. Pattison. Am. J. Surg. 96:183-192 (Aug.) 1958 [New York].

The authors utilized end-to-side portacaval shunt, performed through a right thoracoabdominal incision, as an emergency procedure during acute bleeding from esophagogastric varices in 11 selected patients, 7 women between the ages of 19 and 67 years, 1 9-year-old girl, and 3 men between the ages of 48 and 63 years, with hepatic cirrhosis. The indications for emergency surgical intervention in these patients were ineffectiveness of tamponade in controlling bleeding in 1, immediate recurrence of bleeding on release of tamponade in 5, early recurrence of bleeding while recovering from previous hemorrhage in 4, and an erroneous diagnosis of bleeding peptic ulcer in 1. All patients were either actively bleeding at the time of the surgical intervention or had bled actively within 12 hours of it. None were in coma and only 2 had shown encephalopathy in the days before the surgical intervention. Liver biopsy specimens obtained during the surgical intervention confirmed the diagnosis of cirrhosis in all patients.

Four of the 11 patients died in their early postoperative period. Death resulted from irreversible shock 5 hours after the surgical intervention in 1 patient; another patient died 24 hours after the operation in coma; and the remaining 2 died in coma on the 7th and 36th postoperative day respectively. Three of the 4 deaths occurred in patients who had marked jaundice at the time of the operation. In none of the survivors was the total serum bilirubin level over 1.8 mg. per 100 cc. Late death occurred in 2 of the 7 survivors; both died in hepatic coma, one 2 years after surgery and the other 3 months after the intervention. Five patients are alive 2½, 4, 20, 26, and 27 months after the surgical intervention. With 1 exception, bleeding from esophagogastric varices ceased abruptly with completion of the surgical intervention in all patients even though balloon tamponade was not employed postoperatively in any. The exceptional patient had been bleeding almost continuously for 32 days and balloon tamponade had been used intermittently for 16 days preceding the operation; 4 hours after the surgical intervention, hematemesis of 200 cc. necessitated the reinstitution of tamponade for 10 hours. After removal of the tamponade tube at this time no further bleeding was observed.

The conclusion that portal decompression as accomplished by end-to-side portacaval shunt can be relied upon to terminate varical bleeding, in almost all cases, immediately, appears to be warranted. Preoperative jaundice was an unfavorable sign with regard to survival. Comparison of results obtained in these patients with those in whom emergency temporizing procedures were utilized suggests that the operative mortality differs little and that effective control of bleeding is more likely to be obtained by portacaval shunt. It still remains doubtful that any of the emergency operations currently in use will significantly improve the total mortality for these cirrhotic patients with severe bleeding from esophagogastric varices.

The Diagnosis and Clinical Management of Hepatic Coma in Surgical Patients. J. S. Najarian, H. A. Harper and H. J. McCorkle. Am. J. Surg. 96:172-182 (Aug.) 1958 [New York].

The authors studied the diagnosis of hepatic coma and the response of this syndrome to treatment in 64 surgical patients, 48 with portal cirrhosis associated with gastrointestinal hemorrhage and 16 with surgically constructed portal-systemic venous shunts. Hepatic coma is a neuropsychiatric disorder which should be suspected as a possible causative factor in patients with such clinical manifestations as changes in the state of consciousness, motor activity, and changes in deep tendon reflexes. Since increased concentration of ammonia in the blood of patients with hepatic coma is probably one of the most important factors in the occurrence of this syndrome, these manifestations were used for dividing the ammonia intoxication into 3 encephalopathic stages including delirium, stupor, and coma. The concentration of ammonia in the blood of over 90% of the patients was found to correlate with the clinical progression of the encephalopathy. Electroencephalographic changes were found to be helpful in making the diagnosis of hepatic coma in some patients.

Methods for decreasing the production of ammonia by the action of intestinal bacteria on nitrogenous substrates, as well as for the control of the concentration of this metabolite in the blood, were an important part of the clinical management of hepatic coma. When gastrointestinal hemorrhage was the precipitating cause of hepatic coma, control of bleeding and prompt removal of the accumulated blood from the gastrointestinal tract by catharsis, gastric lavage, and enemas were found to be essential in controlling the production of ammonia. The oral administration of broad-spectrum antibiotics was also valuable in reducing the ammonia within the gastrointestinal tract. It was essential to withdraw the dietary protein completely during the acute phase of hepatic coma, and in order to avoid recurrence of this syndrome a limitation of protein intake often was necessary during the chronic state of ammonia intoxication. The amino acid arginine was used to enhance detoxification of ammonia within the body of 59 of the 64 patients; 25 Gm. of arginine was given intravenously over a 2-hour period and the infusion was repeated if necessary in 8 to 12 hours. There was a prompt decrease in blood ammonia concentrations associated with clearing of the sensorium. Although 44 of the 64 patients were initially in stupor or coma when treatment was started, only 19 patients died, an over-all mortality rate of only 30%.

Treatment with Androgens for Mammary Carcinoma in the Woman. A. E. Vaccato and F. De Bernardis. Minerva med. 49:2345-2351 (June 13) 1958 (In Italian) [Turin, Italy].

Treatment with testosterone alone or combined with other therapeutic procedures was instituted in 298 women with mammary carcinoma at the Surgical Clinic of the University of Padua during the past 10 years. Sixty-six patients were unmarried women (22.1%), 185 were married and had had children, and 47 were childless married women. Mammary carcinoma without clinical evidence of metastases was present in 110 women (36.9%) at the beginning of chemotherapy. The largest incidence of mammary carcinoma per age bracket was found among women in their fifties or sixties. Simple mastectomy was performed on 5 patients with fibrocystic mastopathy. Mastectomy according to Halsted's technique with dissection of the axillary fossa was performed on 258 patients or with dissection of the supraclavicular space on 11 patients. Twenty-four patients were in an inoperable state, due to the extensive metastases. After surgery a course of roentgenotherapy was given to all patients except in 6 who were in the inoperable state.

Chemotherapy, which was instituted in all patients, consisted of intermittent administration of testosterone in several courses. The dosage of each course gradually increased from 300 mg. up to 5-6 Gm. per course. Testosterone was combined with paraoxypropiophenone in the treatment of 6 inoperable patients; or it was combined with prednisone in other 13 inoperable patients. The survival time in this series of patients, even among those with diffuse metastases, was longer than in other groups, which were previously observed. This improvement can be ascribed to a combination of better surgical therapy, perfection of roentgenologic treatment, earlier diagnosis, and, in particular, to a more potent hormonal therapy. Metastases, which mostly invaded the lungs, developed in 129 patients (47%) in a period between 6 months and 7 years after chemotherapy had been instituted. Metastases in the bones were the most responsive to the testosterone treatment.

Transantral Decompression for Malignant Exophthalmos. J. S. Walker and G. L. Porter. A. M. A. Arch. Otolaryng. 68:152-155 (Aug.) 1958 [Chicago].

Thyrotropic exophthalmos, which is also described as malignant exophthalmos, is manifested by protrusion of the eyes of a "noncompressible" type (the so-called hard orbit) and is associated with some or all of the following: edema of the eyelids, chemosis of the conjunctiva, engorgement of orbital and ocular vessels, paresis or paralysis of extraocular muscles, and failing vision. The treatment of malignant exophthalmos may require medical management only, or a combination of medical management and surgery. Basically, 3 surgical approaches are in use; the first attempts protection of the eye by using the lids or conjunctiva for covering; the second attempts to reduce the mass packed in the orbit by the removal of intraorbital fat; and the third accomplishes a true decompression by the removal of confining bony wall. In 4 instances excellent results were obtained by these authors with transantral decompression, which indicates that this procedure is worthy of serious consideration and further trial. The technique is simple and is essentially that of Hirsch, who introduced the procedure successfully in 1929, save for the modification whereby the intraorbital canal is removed. The orbital floor is removed after access is gained through a sublabial incision and exposure and removal of a portion of the anterior antral wall. Anteroposterior incisions through the fascia divide the floor into 3 strips; the center strip is left intact and the outer strips are divided by an incision in the coronal plane, affording further relief of intraorbital pressure. An inferior meatal window completes the surgery, and the wound is closed and an elastic bandage with mild pressure is placed over the eyes. Prompt improvement was apparent within 3 days, and an almost complete recovery from acute symptoms took place within the week. No complications have occurred.

Neurofibrosarcoma of Cranial Nerve Origin. S. G. Economou, H. W. Southwick and D. P. Slaughter. A. M. A. Arch. Surg. 77:271-281 (Aug.) 1958 [Chicago].

The authors report on 7 male and 7 female patients between the ages of 6 and 59 years, with neurofibrosarcoma of cranial nerve origin, on whom 32 operations were performed. Eight patients had subcutaneous nodules, 4 had tumors arising within deeper structures of the head and neck, and 2 had an associated neurofibromatosis. Ten patients are alive and without evidence of recurrent tumor for postoperative periods ranging from 2 to 9 years, with 4 being free of disease for over 5 years after the operation. One patient is alive but has recurrent disease, 2 patients died of their disease, and 1 patient died of intercurrent disease without evidence of neurofibrosarcoma. In the absence of specific nerve involvement, subcutaneous neurofibrosarcomas of cranial nerve origin should be treated by adequate local excision. If the nerve can be identified, it should be exposed far beyond the tumor mass in a search for synchronous tumors and the nerve should be resected as far proximally as possible. Neurofibrosarcomas involving more deeply situated nerves can be treated most effectively by an "en bloc" excision of the involved area and further proximal excision of the nerve.

Neurofibrosarcomas have a high incidence of local recurrence. This is believed to be a manifestation of multicentric origin of tumors along the involved nerve. Neurofibrosarcomas metastasize through venous channels, and surgical interventions for their removal in the area in question should not be designed as for those lesions which metastasize predominantly through lymphatics. There appears to be a correlation between the microscopic gradation of the tumor and the postoperative salvage. The longest survivals were observed in the patients with relatively well-differentiated tumors; the degree of tumor anaplasia seems to have a clear relationship to the surgical curability of the tumor. Likewise, tumors possessing a pseudocapsule have a more favorable prognosis. Patients with generalized neurofibromatosis in whom neurofibrosarcoma occurs have a uniformly poor prognosis.

Results of Thoracic Surgery in the Treatment of Pulmonary Tuberculosis. H. W. O. Frew, K. Fraser and W. McL. Gregor. Brit. J. Tuberc. 52:244-254 (July) 1958 [London].

This report deals with the first 200 consecutive patients with pulmonary tuberculosis who were treated in a thoracic surgery unit between September, 1952, and October, 1955. The patients were representative of those receiving sanatorium treatment. All had undergone routine treatment with various courses of chemotherapy and it was only after prolonged sanatorium treatment (a minimum of 3 months) that many were considered suitable for surgery. Many had long-standing extensive lesions; the disease was bilateral in some of the patients, while in others it was confined to 1 lobe and presented essentially as areas of unclosed cavitation or large and relatively soft tuberculomas. There were 105 men and 95 women. All operations were performed by 1 of the authors. When the unit opened in 1952, 2-stage thoracoplasties were being performed, but after some months this operation was replaced by 1-stage thoracoplasty. One-stage thoracoplasty entailed removing the entire first rib, almost half of the second, 2½ in. of the third, 1½ in. of the fourth ribs and occasionally a small portion of the fifth rib. The lung apex was dissected out by dividing the fascial bands which hold it up to the brachial plexus and first thoracic vertebra. It was then stripped down to below the azygos vein on the right side, or the aortic arch on the left, and held in its new position by stitching the pleural cap of the lung apex to the periosteum of the vertebrae. This type of thoracoplasty preserves much more healthy lung than the older 2-stage and 3-stage operation, and deformity is minimized.

In 1952 extrapleural pneumothorax was popular, but this operation has largely been replaced by more permanent procedures. In general, resection was carried out for tuberculomas, a medium-sized or large cavity, anteriorly placed disease, lower lobe disease, a collapsed and/or bronchiectatic lobe, or a destroyed lobe or lung. The extent of disease found at operation dictated the amount of lung tissue resected: 1 or more segments, 1 or more lobes, or pneumonectomy. A modified type of thoracoplasty was done at the same operation in all cases of lobectomy or pneumonectomy. The total number of operations was 211, several patients requiring more than 1 form of surgical treatment. The thoracoplasties consisted of 58 1-stage, 53 2-stage, and 1 3-stage operations. Patients in whom resection was done had at least 1 drainage tube, and if much alveolar leakage was anticipated, 2 drains were used; both were inserted low in the axillary line and 1 was carried right up to just below the first rib. This long tube had 3 openings to drain different levels within the chest. If there was considerable escape of air, motor suction was applied to both tubes. The drains were removed in 2 to 3 days. Any apical air space remaining was treated by aspiration. Intensive physiotherapy was insisted on, with special emphasis on breathing exercises, expectoration of sputum, and the prevention of skeletal deformity. The patients were kept in bed for 6 to 8 weeks after the operation, and received training in hospital for 5 months after surgery. All operations were timed to coincide with a course of chemotherapy.

Four patients died as the result of the operation, and 4 others died later. Sixty-seven per cent of the 188 patients who could be traced at least 2 years after the operation were regarded as cured and all but 3.2% derived considerable benefit from the treatment. Whereas before operation the sputum of 84% of the patients contained tubercle bacilli, it was free from bacilli after operation in 95.9% of the patients. Eighty per cent of the patients were able to resume their work.

Otalgia with Oesophageal Hiatus Hernia. W. D. F. Malherbe. Lancet 1:1368-1369 (June 28) 1958 [London].

The disturbances caused by hiatus hernia may appear completely unrelated to the gastrointestinal tract, with the result that patients are referred to specialists in other fields. Hiatus hernia may cause precordial symptoms which closely simulate angina pectoris. An apparently causeless secondary anemia may exist, the hernia being discovered only after careful examination of the gastrointestinal tract. Reflex vagal disturbances may lead to crises of bradycardia with a fall in blood pressure and loss of consciousness. Hiatus hernia may also present with pain in the ears. Since 1956 the authors observed 3 patients with a combination of earache and abdominal symptoms, who were found to have hiatus hernia. The anatomic basis for this phenomenon is that both esophagus and external auditory meatus are supplied by the vagus nerve, and the pain is probably referred. The earache disappeared after effective treatment of the hernia.

Analytic Investigations on Bronchial Carcinoma: A Clinical Statistical Study on 801 Bronchial Carcinomas. U. J. Wassner and W. Knothe. Arch. klin. Chir. 288:462-484 (No. 5) 1958 (In German) [Berlin].

The number of patients who come to clinics with bronchial carcinoma is constantly increasing, and the duration of the history of symptoms, that is, the time that elapsed between the appearance of the first symptoms and the patient's admission to the clinic, is becoming shorter than in former years. Despite the shorter histories, however, the percentage of operable tumors and the length of survival are not increasing to the same extent. This suggested that the duration of symptoms before treatment is only one aspect which greatly depends on other factors. In order to ascertain the importance of the interrelationship of various factors influencing the development of a bronchial carcinoma, the 801 patients studied had to be divided into smaller groups that were comparable. The typical age of onset of bronchial carcinoma is between 49 and 61. The best prospects for operation and for length of survival cover this same span of years. The duration of the history of symptoms depends on the rapidity of growth of the bronchial carcinoma. The rapidity of growth in turn is decided by the histological type of the tumor. In the case of squamous cell carcinoma the history of symptoms usually extends over 5 months, whereas in case of undifferentiated parvicellular carcinoma it is usually only 3 months. However, the rapidity of growth of the various types of ulcer is determined also by the age of onset. The squamous cell carcinoma grows at about the same rate in patients of different ages, but the growth rate of the parvicellular carcinoma increases noticeably with advancing age. The length of history or the duration of symptoms is dependent also on the location of the bronchial carcinoma. In the presence of a carcinoma of the main bronchus the history of symptoms is usually 5 months, whereas in the case of a lobar carcinoma it is 3 months.

Studies made it appear probable that transitional forms from squamous cell carcinoma to undifferentiated parvicellular carcinoma occur usually in patients between the ages of 40 and 50 years. Operability and chance of survival depend also on the histological characteristics of the tumor, its location, the age of the patient at the time of onset and the duration of symptoms. A shorter history of symptoms as such is of only slight significance. The course of bronchial carcinoma is usually already decided when the first tumor symptoms appear, this is true especially in the undifferentiated parvicellular bronchial carcinomas. In order to combine and to express the interdependence of the various aspects of bronchial carcinoma, the authors describe the concept of the "carcinoma number," which they believe will be helpful in ascertaining the prognosis of the patient with bronchial carcinoma. This number is arrived at on the basis of an equation in which the quotient, resulting from the division of the patient's age (in years) by the duration of symptoms (expressed in months), is multiplied by a factor expressing the histological character of the carcinoma and by a factor expressing the location of the growth.

Congenital Absence of the Gallbladder and Cystic Duct. B. Pines and D. M. Grayzel. A. M. A. Arch. Surg. 77:171-180 (Aug.) 1958 [Chicago].

The authors report 5 instances of congenital absence of the gallbladder and cystic duct in the presence of normal biliary passages: the first, in a 74-year-old man with symptoms of epigastric pain, nausea, vomiting, malaise, and increasing jaundice of 1 week's duration who was operated on; and the others, in 4 male patients between the ages of 22 months and 83 years in whom this rare anomaly was an incidental finding at autopsy performed at the Jewish Hospital in Brooklyn, N. Y. One hundred fifteen cases of congenital absence of the gallbladder and cystic duct, observed with almost equal frequency at operation and at autopsy, were collected from the literature. Preoperative diagnosis of this condition has never been made. It is usually observed during the course of celiotomy which is performed for symptoms that are suggestive of calculous cholecystitis and/or choledocholithiasis. When it is observed at autopsy, it is an unsuspected, incidental finding. The most commonly accepted theory is that this condition is the result of a disturbance of the embryonal development of the hepatobiliary tree which has been reviewed in order to elucidate the unknown causation of the anomaly. Emphasis is placed on the fact that congenital absence of the gallbladder and cystic duct predisposes the bile passages to anatomic and physiological derangements, which, in turn, lead to inflammation of the bile ducts and stone formation in a large number of patients. An understanding of the nature of the pathological sequelae which are associated with agenesis of the gallbladder is vitally important to assure rational management of these patients.

Although no pathognomonic clinical syndrome exists to indicate absence of the gallbladder, there is generally a consistent pattern of characteristic symptoms, such as shown by the 74-year-old patient, which may alert the clinician who has a high index of suspicion. Definitive surgical treatment is indicated in all symptomatic patients in whom the gallbladder and cystic duct are congenitally absent. The procedures vary with the nature of the associated alterations in the bile passages. Sphincterotomy in conjunction with T-tube drainage was successful in some patients whose cases were collected from the literature and in whom ampullary dysfunction was suspected to be the cause of the patients' symptoms, especially when the common-bile-duct passage was wide and no calculi were present. In other patients with agenesis of the gallbladder in whom the common duct was dilated to cystic proportions, a Roux-en-Y choledochojejunostomy was successful in 2, and in 2 others a resection of the cystic area and an end-to-end anastomosis of the common duct resulted in a cure. When stones were present, choledocholithotomy, prolonged T-tube drainage, and sphincterotomy were the preferred treatment. In most patients, prolonged drainage gave optimal results.

Gallstone Ileus. J. P. Rijken. Nederl. tijdschr. geneesk. 102:1298-1301 (July 5) 1958 (In Dutch) [Amsterdam].

The author discusses the pathological anatomy, clinical diagnosis, and treatment of gallstone ileus on the basis of a review of the literature and of 14 patients with this disorder observed in the surgical department of his hospital during the period from 1941 to 1957. The group included 12 women and 2 men. Four of these patients died after surgical treatment. Three of 7 patients died before 1947, but after 1947 only 1 of 7 patients died. The patients ranged in age from 53 to 86 years; the average age was 70.6 years. The diagnosis of gallstone ileus had been considered in only 2 of the patients. Five of the 14 patients had a history of gallstone symptoms. Signs of obstruction had existed for an average of 6 or 7 days before operation. The stone was found in 12 patients in the small intestine, in 1 in the sigmoid, and 1 patient had multiple stones.

The author emphasizes the following points: 1. Intestinal obstructions caused by a gallstone have a much higher death rate than do those from other causes. 2. This is due to the fact that the diagnosis is made rather late and also to the advanced age of the patient. 3. Treatment consists in the prompt removal of the stone by enterotomy, after fluid and electrolyte balance has been restored. 4. The advisability of cholecystectomy at a second operation should be considered. 5. Roentgenologic examination should not be restricted to the gallbladder but should be extended to the gastrointestinal tract, so as to detect possible cholecysto-enteral fistulas. 6. The high death rate of gallstone ileus can be reduced by more thorough clinical and roentgenologic studies. The more frequent use of cholecystectomy in patients with gallbladder disease might prevent gallstone ileus.

The Surgical Management of Chronic Tophaceous Gout. W. A. Larmon and J. F. Kurtz. J. Bone & Joint Surg. 40A:743-772 (July) 1958 [Boston].

This report is based on the surgical management of 23 patients with chronic tophaceous gout admitted to the Veterans Administration Hospital, Hines, Ill., from 1947 to 1957. Ninety-nine surgical procedures were performed in the 23 patients. Gout until recent times was attributed to dietary indiscretion, but in the past decade it was shown that the increased level of uric acid in the blood is due to a metabolic defect in the formation of uric acid, which is a normal end-product of purine metabolism. Its source may be exogenous from food or endogenous from cellular metabolism. A third source of uric acid may be by direct synthesis from simpler compounds. This concept is based on studies with radioactive isotopes and indicates that the gouty patient forms an abnormal amount of uric acid from these various sources. Tophi do not form in all patients suffering from gout. Tophaceous gout is a late manifestation of the severe form of this metabolic disturbance. The majority of patients with gout have recurring attacks of acute arthritis with no demonstrable permanent joint changes between attacks. If routine studies were carried out in patients with acute arthritis to determine the presence of elevated serum uric acid levels, many more cases of gout would come to light in a stage amenable to medical management.

The authors feel that surgical intervention is warranted when tophi are unsightly, are painful, interfere with tendon function, or threaten to cause skin necrosis and ulceration; also when tophi have ulcerated or sinuses are present; when tophi encroach on nerves causing symptoms of compression; when joints are being destroyed and are painful; and when the total amount of urates in the body can be lowered by excision of readily accessible large tophi. General anesthesia is preferable to local, because distention of tissues with the local anesthetic agent may impair the blood supply and cause necrosis of skin.

Incisions should parallel the blood supply of the part. Counter-incisions in the fingers and toes should be avoided as necrosis of the intervening skin may result. Sharp dissection is preferred when feasible, but curettage may be done to remove the maximum amount of urates while preserving essential structures. Gentle handling of tissues is necessary. Wounds should be irrigated to prevent necrosis and to aid in removal of the tophi. Resection of joints, arthroplasty, and arthrodesis of painful joints may lessen pain and improve function. Skin-grafting may hasten healing after removal of the gouty deposits when granulation tissue appears. Minimal suturing of wounds is advisable in order to preserve blood supply and to allow escape of liquefied deposits when removal of the tophus is incomplete. Pressure dressings and splints minimize dead space, help prevent hematomas, and put the parts at rest so that healing may occur. Prolonged splinting is to be avoided as ankylosis may occur. Amputation of toes may be necessary, but every effort should be made to preserve the fingers. A definite plan of preoperative and postoperative medical management helps to prevent complications and acute attacks following surgery.

NEUROLOGY & PSYCHIATRY

Neurological Disorders Associated with Asian Influenza. B. McConkey and R. A. Daws. Lancet 2:15-17 (July 5) 1958 [London].

The authors observed, during October and November of 1957, 4 patients in whom neurological disorders followed a febrile illness suggestive of influenza. Neurological involvement followed 4 or 5 days after the onset of a febrile illness. That this illness was Asian influenza appears to have been established by the results of the complement fixation tests in 3 cases. The high infectivity of the disease is shown by its spread in the family of the first 2 patients, for the other 4 members of this family had febrile illnesses and blood from 3 showed evidence of recent infection with influenza A (Asian). The daughter whose blood was examined also had involvement of the nervous system following her attack of influenza. She complained of severe headache and became drowsy, but recovery was uneventful. The fourth patient had an illness very like lymphocytic choriomeningitis, and was the only one in whom a cell response developed in the cerebrospinal fluid. The illness followed what was thought to be Asian influenza, and although the results of the complement fixation tests do not altogether exclude influenza C and mumps, the authors believe that the neurological disorder in this case, as in the others, followed Asian influenza. Three of the patients were very ill and caused some anxiety, but when recovery began it was rapid. In 2 patients the electroencephalogram, although grossly abnormal at the height of the illness, soon reverted to normal. The handwriting of 1 of the patients has deteriorated, and this is probably evidence that recovery has not been as complete as was at first thought.

A Clinical Evaluation of Acetazolamide (Diamox) in the Treatment of Epilepsy in Children. J. Holowach and D. L. Thurston. J. Pediat. 53:160-171 (Aug.) 1958 [St. Louis].

Although first introduced as a diuretic, Diamox (acetazolamide) subsequently was found helpful in the control of epilepsy. The authors used Diamox in 56 patients from the outpatient clinic of St. Louis Children's Hospital. These patients had not been completely controlled with their previous medications, which ran the gamut of available anticonvulsants. Their ages ranged from 3 months to 16 years, and the duration of their attacks had been from 2½ months to 13 years. Of the 56 patients, only 6 had more than 1 type of seizure at the onset of Diamox therapy. The dosage of Diamox was empirical in all cases, ranging from 250 to 1,000 mg. per day. Diamox dosage for epilepsy has variously been reported from 8 to 36 mg. per kilogram of body weight daily, but there is evidence that the drug can be effective in doses of less than 4 mg. per kilogram of body weight per day.

Seizures were completely controlled in 35 of the 56 patients, were improved well over 50% in 9 patients, and persisted unchanged in 12 patients. The anticonvulsant action of Diamox is prompt. Results are often evident within hours. For this reason, small doses, if ineffective, should be increased quickly to tolerance. The maximum recommended dose is 1,000 mg. per day. The usefulness of Diamox in the treatment of epilepsy is limited by the tendency for development of tolerance. The mechanism of this resistance is unknown. Under these circumstances, resuming Diamox treatment after an interval of time may again be beneficial. Despite the tendency for development of tolerance, the prompt control of many cases of epilepsy of diverse types with few side-effects makes Diamox a valuable drug in the clinical management of epilepsy.

Is Multiple Sclerosis a Spirochetosis? Additional Factual Material. H. C. R. Simons. Deutsche med. Wchnschr. 83:1196-1200 (July 11) 1958 (In German) [Stuttgart, Germany].

Simons cites a preliminary report he published in 1957 to the effect that he in Bern, Switzerland, and G. Steiner of Detroit in 1954 had independently observed (not then published) living spirochetes in the cerebrospinal fluid after acute exacerbations of multiple sclerosis. The author had also reported the first successful visualization of Steiner's Spirochaeta myelophthora in the stained cerebrospinal fluid of a patient with tetroplegic multiple sclerosis. In this paper he presents additional factual material on the question of multiple sclerosis as a spirochetosis. He mentions Ichelson's report on obtaining Sp. myelophthora in pure culture from the cerebrospinal fluid of a high percentage (78%) of patients with neurologically proved multiple sclerosis. Ichelson recently succeeded in developing a skin reaction in which spirochetes cultured from multiple sclerosis patients served as antigen, and with the aid of L. Roach he was able to develop a complement fixation test.

Histories and autopsy reports are presented with histological studies on the central nervous system of several patients with multiple sclerosis. In the histological studies, the author gives particular attention to the use of disintegration procedures either with the thedan-blue-potassium chlorate method or with the simplified and improved thedan-blue-ammonia method. He feels that the findings presented greatly favor the role of spirochetes in the etiology of multiple sclerosis. Whenever he showed slides of the spirochetes discovered in multiple sclerosis lesions to bacteriologists, pathologists, or neuropathologists, their spirochetal nature was never questioned. He discusses factors that speak for the pathogenicity of multiple sclerosis spirochetes.

Reserpine in Advanced Psychoses. L. O. Norman. Nord. med. 59:798-802 (June 12) 1958 (In Swedish) [Stockholm].

Oral reserpine therapy was applied in 145 women patients with advanced chronic endogenous psychosis, including 136 with schizophrenia. Most of the patients had been in a hospital for many years. In 23 cases prefrontal leukotomy had previously been done, and insulin coma treatment had been given in 60 cases during acute exacerbations. In 102 patients there was more or less marked psychic improvement during the treatment. In a number of cases reserpine had only a generally tranquilizing effect with reduction of motor hyperactivity and a lessening of aggressiveness, impulsivity, and negativism, making care easier for the personnel. Often there was even a definite decrease in the schizophrenic autivism. The initial reserpine dosage was as a rule 9 mg. daily in 3 doses, usually continued for several weeks until favorable effect was noted or by-effects set in, when the dosage was decreased to 2-6 mg. daily and later possibly further. In the author's opinion a significant improvement may be looked for in ⅓ of the patients and the possibility of their being able to leave the hospital may be expected in only about 1/10 of the patients. Because of the by-effects the treatment, at least at first, should be carried out in a hospital where there is constant medical control; under such circumstances the complications which reserpine may cause seldom involve more serious risks for the patient. A favorable effect was seen more often in catatonic and paranoid schizophrenics, in patients with intact or fairly intact reactability, and in patients who had had previous remissions. Unfavorable reactions were seen in about 15% of the cases. In 52 cases the optimal effect was attained within 3 weeks after the start of treatment, in 36, after 3-6 weeks, and in 12, later. Of the 14 patients able to leave the hospital after reserpine treatment only 2 on follow-up after half a year had again required hospital care, 8 could be cared for at home, and 4 were regarded as cured.

Active Immunization Against Poliomyelitis with a Vaccine of Attenuated Virus: I. Theoretic Foundation and Selection of Strains. J. D. Verlinde. Nederl. tijdschr. geneesk. 102:1138-1143 (June 14) 1958 (In Dutch) [Amsterdam].

Sabin's vaccine is being tried in the Netherlands on small groups of patients. This vaccine, prepared from selected attenuated (non-neurotropic) types of poliomyelitis virus, is administered by mouth. The theoretic foundation of vaccination with the living virus is the expectation that after oral administration it multiplies in the alimentary canal and causes an immunizing intestinal infection. Fortunately, enterotropy and neurotropy are separated. It is of practical importance that when types 1, 2, and 3 of poliomyelitis virus are administered simultaneously, interference may result in that the dominating type 2 virus often interferes with the multiplication of type 3 virus, so that there is no immunization against type 3. Thus it may be desirable that the 3 types be administered separately. If administered at intervals of 3 weeks each type will have an opportunity to multiply.

Some partially attenuated strains may cause viremia. This characteristic must be regarded as undesirable, since it may lead to infection of the central nervous system. As regards the formation of neutralizing antibodies there is no essential difference between active immunization with Salk vaccine, treatment with living attenuated virus, and natural infection. Since the ingested virus is excreted in the stools, it is of the utmost importance, not only for the vaccinated individual but also for his environment, that the virus should be non-paralytogenic for man, and as homogeneous and stable as possible. The most reliable method of selecting suitable strains is the use of single plaque progeny as suggested by Sabin.

Active Immunization Against Poliomyelitis with Attentuated Virus: II. First Report on the Use of Sabin Vaccine in the Netherlands. J. D. Verlinde, J. B. Wilterdink, B. Hofman and A. Kret. Nederl. tijdschr. geneesk. 102:1144-1149 (June 14) 1958 (In Dutch) [Amsterdam].

The authors describe the result of vaccination experiments with Sabin's method on 40 volunteers in the Netherlands. These volunteers, including children and adults, with and without homotypic antibodies, were fed Sabin's highly attenuated strains of the 3 types of poliomyelitis virus. Single plaque progeny of each type was administered at 3-week intervals (first type 1, then type 3, and finally type 2), the dose being 0.1 ml. of a 10^{-1} dilution of tissue culture fluid in Hanks' solution in a teaspoonful of jam or milk. With only few exceptions, an asymptomatic alimentary infection and development of antibody were demonstrated in persons without pre-existing, high-avidity homotypic antibodies. In 1 person neither alimentary infection nor antibodies developed, even after repeated feeding with a double dose, presumably because of a natural resistance of the alimentary tract. The duration of the alimentary infection (virus excretion) varied from 7 to 44 days. In persons with preexisting high avidity homotypic antibody, alimentary infection was rare, and, if present, of shorter duration, while less virus was excreted per gram of stool than by nonimmune persons. Yet approximately 50% of all vaccinated persons showed a rise of antibody titer.

Thirty-nine strains (14 of type 1, 6 of type 2, and 19 of type 3), which were isolated from the stools of 21 vaccinated subjects were tested for neurotropism by intraspinal and intracerebral inoculation of Cynomolgus monkeys. None of the type 1 and type 2 strains showed any increase of neurotropism, but a slightly increased neurotropism was seen in 3 type 3 strains isolated from the stools of 2 persons. This increase was so slight that only very high doses proved to be paralytogenic on intracerebral inoculation. It is of the utmost importance that this increased neurotropism was demonstrable only in strains isolated 15, 16, and 21 days after feeding, whereas strains of the same type isolated from the same individual either earlier or later did not show any increase of neurotropism. This indicates that the alimentary tract does not selectively favor the development of neurotropic virus particles. So far there seems to be no reason to assume that this method of vaccination might lead to the circulation of virus with a high neurotropic activity.

Intracranial Venous Thrombosis in the Puerperium. G. Dalle Ore and R. Ruberti. Policlinico (sez.prat.). 65:894-903 (June 9) 1958 (In Italian) [Rome].

The author reports on 4 patients with intracranial venous thrombosis in the puerperium. One woman, a tertigravida aged 35, developed intermittent convulsive seizures followed by coma 7 days after delivery. The comatose state persisted for 2 days and was followed by gradual improvement and complete recovery in one week. A woman aged 32 complained of headache in the left frontotemporal region 2 days before the delivery. Pain gradually increased and on the 9th day after delivery difficulty in speech, convulsive seizures, hemiparesis, and right-sided hemiplegia developed successively. The following day clonic seizures involving the left side of her limbs developed. There were traces of blood in the cerebro-spinal fluid. The critical state persisted for 3 days, after which a slow improvement followed, and the patient was discharged on the 20th hospital day. Treatment consisted of administration of heparin, anticonvulsants, hypodermoclysis, and antibiotics. On discharge she was able to move the limbs on the right side and to speak slowly. The patient died suddenly of pulmonary embolism 10 days after the discharge. She was the only patient in this series who succeeded in overcoming the critical stage of the disease despite the presence of grave symptoms associated with a bilateral neurological syndrome.

The disease in 2 women, aged 23 and 33, respectively, was characterized by episodes of generalized convulsions, followed by a period of relative calmness, which may be attributed to the functioning of a collateral venous circulation. A subsequent sudden deterioration of the symptoms, marked by bilateral loss of neurological responses terminated in the death of both patients. The main differentiating feature of the intracranial venous thrombosis in the puerperium from the incidence of acute vascular disorders of arterial origin is the gradual development of the paralysis within a few hours, which under favorable circumstances subsides relatively rapidly and thoroughly. Cerebral angiography has proved to be the most useful diagnostic aid for intracranial venous thrombosis in the puerperium in this group of patients.

GYNECOLOGY & OBSTETRICS

Nystatin in the Office Treatment of Vaginal Moniliasis. L. J. Caruso. New York J. Med. 58:1688-1690 (May 15) 1958 [New York].

The author believes that in this antibiotic era leukorrhea with pruritus is more likely to be caused by monilial (Candida albicans) vaginitis than by trichomonal vaginitis. The increase in monilial infection seems to be due not to an enhanced virulence of C. albicans but rather to the fact that antibiotics often eliminate a large segment of intestinal saprophytic bacteria which appear to have a suppressive effect on the growth of Candida organisms. Furthermore, corticosteroid therapy seems to be accompanied by conditions favorable for the development of moniliasis. There may also be other, as yet unrecognized, factors related to the increase of clinical moniliasis.

This report is concerned with the use of nystatin vaginal tablets in 26 women in whom vaginal moniliasis had been demonstrated by laboratory tests. Treatment consisted solely of the insertion of 1 nystatin vaginal tablet on retiring. Clinical and mycologic cure was obtained in 24 of these 26 patients. Twenty-one of the 26 patients were cured (negative culture and asymptomatic) after the initial course of intravaginal therapy with 1 nystatin tablet each day for 14 days. The remaining 5 patients were improved but still showed positive growth on reculture. A second course of nystatin for 7 days resulted in a cure in 3 patients and the persistence of moniliasis in 2. Reinfection from the husband in these 2 patients was not ruled out, but failure to use the nystatin vaginal tablets according to instructions was felt to be the major cause of unsatisfactory results in these subjects.

PEDIATRICS

Pituitary Dwarfism: Diagnosis and Treatment. M. M. Martin and L. Wilkins J. Clin. Endocrinol. 18:679-693 (July) 1958 [Springfield, Ill.].

The authors report on 6 female and 20 male patients with pituitary infantilism who were followed past the age of puberty. Five female and 2 male patients had a neoplasm in the region of the sella turcica and 1 female and 18 male patients had idiopathic hypopituitarism. The time at which growth retardation became manifest varied but tended to be after the age of 3 years and showed itself earlier in the patients with idiopathic hypopituitarism than in those with tumor. The 26 patients showed permanent sexual infantilism and considerable stunting of growth with a mean lag in height age of 5.8 years. Function studies of target glands controlled by the pituitary indicated, apart from growth hormone and gonadotropin deficiency, impairment of thyroid and/or adrenocortical activity in 20 (75%) of the 26 patients as judged by serum cholesterol and protein-bound iodine levels, water diuresis, insulin sensitivity and 17-hydroxycorticoid excretion. It is therefore concluded that, when lack of either thyrotropin or adrenocorticotropin may be inferred from hypofunction of the target organs in a dwarfed child, the diagnosis of hypopituitarism can be strongly suspected without awaiting failure of sexual maturation. Psychological evaluation did not indicate any dependent relationship between hypopituitarism and intelligence quotient, but a dependent relationship to personality development, i. e., personality reflecting the problems concomitant with small stature.

Thirteen patients were treated with thyroid and 4 were given in addition a trial treatment with cortisone administered orally in daily doses of 25 mg. Administration of these drugs was of no benefit in the absence of conclusive evidence that these hormones were deficient. Even when the laboratory data indicated their use, the results, though subjectively encouraging, were objectively disappointing. Sex hormone substitution therapy was given to all the patients once it became obvious that spontaneous puberty was not to be expected. Most boys were given testosterone, either as long-acting testosterone cyclopentylpropionate or testosterone enanthate, once every 3 to 4 weeks in doses of 200 to 400 mg. Androgen therapy resulted in a growth spurt with gain in weight, marked broadening of the frame, and muscular development. The degree of virilization achieved in the patients was considerably below normal. The female patients were treated with androgens as well as estrogens. The administration of methyltestosterone in doses of 10 to 20 mg. daily, in addition to that of stilbestrol in doses of 1 mg. daily resulted in a near-normal growth of pubic hair and a spurt of growth without producing virilization. After 6 to 9 months of combined androgen and estrogen therapy, when development of the breasts, nipples, labia and vagina, estrinization of the vagina, and growth of the uterus had occurred, periodic therapy was instituted unless bleeding had taken place previously. With this treatment, physical maturation was more complete than in the case of the male patients. The improvement in morale and the social and psychological adjustment achieved by these female patients appeared to be better than that of their male counterparts. Early substitution therapy with sex hormones is urged, although not before the usual age of puberty, once the diagnosis of hypopituitarism has been firmly established and there is reasonable certainty that the case is not one of constitutionally delayed growth and adolescence. By relatively early treatment these children may be saved considerable psychological difficulty and may be helped greatly in their social adjustment.

Intracranial Calcification Following Tuberculous Meningitis in Children. J. Lorber. Am. Rev. Tuberc. 78:38-61 (July) 1958 [New York].

Routine serial roentgenograms of the skull were taken in 130 children who recovered from tuberculous meningitis and were followed for 2 to 10 years. Ten children died 21 months to 6 years after the onset of meningitis and 120 were alive at the time of the author's report. All of the 130 children received streptomycin by intrathecal route for various periods. Forty-two patients were treated with streptomycin as the only antimicrobic drug, 40 received aminosalicylic acid in addition, and the last 48 received isoniazid, streptomycin, and aminosalicylic acid. Fifteen children were given tuberculin intrathecally and 6 received streptokinase intrathecally as adjuvants. Pathological intracranial calcification was revealed by the roentgenograms of the skull during life in 63 children (48.4%). In 2 others who died, intracranial calcification and even ossification were observed at autopsy. In most children the calcification became detectable 2 to 3 years after the onset of the disease, but in some it was not detectable for 5 years.

The calcification occurred in 2 main sites: (1) the basal meninges and (2) within the brain substance. Calcification in the basal meninges was by far the more common and was seen in 49 patients (37%). In most patients the meningeal calcification was in the vicinity of the sella turcica, usually above the anterior or posterior clinoids or extending further back. It consisted of a single lesion in 9 patients, but in most of the other patients several smaller lesions formed clusters of calcification either as a solitary plaque, or more commonly as an irregular, broken, branching plaque. Sometimes the plaques formed a ring-like shadow just above the posterior clinoid process. Their situation closely corresponded to that of the cisterna chiasmatica. Much less commonly the exudate calcified in the meningeal spaces of the Sylvian fissure.

Thirty-three of the 130 patients were in the early stage of the disease on admission, 79 had intermediate disease, and 18 had advanced disease; meningeal calcification occurred in 7 (21%) of the 33 patients, in 32 (40%) of the 79, and in 10 (55%) of the 18 patients. Thus the incidence of meningeal calcification increased progressively in relation to the stage of the disease on admission. There was no appreciable difference in the incidence of calcification between those treated with streptomycin alone or with streptomycin combined with aminosalicylic acid, but the incidence of calcification was somewhat less in those treated with isoniazid and streptomycin. The use of adjuvants, intrathecally administered tuberculin and streptokinase, also reduced the incidence of meningeal calcification in selected groups. Intracerebral calcification was seen in 17 children (13%). The incidence was independent of the stage of the disease on admission and of the method of treatment.

The incidence of calcification was higher among children with neurological sequelae than in those who did not have such sequelae; 13 (62%) of 21 children with neurological sequelae had some form of intracranial calcification as compared with 50 (46%) of the 109 children without such sequelae, but the differences were not significant. Intracranial calcified lesions may harbor living tubercle bacilli. All 6 children with late recurrences of the disease had intracranial calcification. It is considered likely that tuberculous meningitis is becoming the most common cause of intracranial calcifications in children.

Frequency of Erythroblastosis. S. L. Leikin, J. J. Rheingold and J. G. Sites. Pediatrics 22:65-71 (July) 1958 [New York].

Blood from 1,125 sets of mothers and infants, 95% of whom were Negroes, was typed and grouped. The blood from mother and infant was found to be incompatible in 230 instances (20.4%). Twelve infants were designated as having ABO hemolytic disease, the diagnostic criteria for which is (1) an abnormal concentration of bilirubin in the cord blood and/or a marked increase in the serum in the subsequent neonatal period, and (2) an elevated reticulocyte or normoblast count and increased microcytosis, spherocytosis, and polychromasia. Jaundice was the first clinical sign appearing in 8 of the patients, and was noted as early as 5 hours and as late as 54 hours. Spleen and liver enlargement was absent in all of the infants, 2 of whom were premature. In only 2 cases were the mothers primigravida. None of the infants had signs of neurological disease during hospitalization or at follow-up study at 1 year of age. The Witebsky slide test appears to be a valuable adjunct in the diagnosis of ABO erythroblastosis.

Therapy of Hodgkin's Disease (Malignant Lymphogranulomatosis). C. Moschidis, K. Kiosoglou and F. Maouni. Ann. paediat. 190:333-341 (June) 1958 (In German) [Basel, Switzerland].

The authors report observations on 35 patients with Hodgkin's disease whom they treated during the decade 1947-1956 at the Children's Clinic of the University of Athens, Greece. The patients ranged in age between 3 and 14 years, 21 being less and 14 more than 8 years old. There were 25 boys and 10 girls. Twenty-three of the children were hospitalized once; the remaining 12 were hospitalized several times for the treatment of Hodgkin's disease. The authors give special attention to 10 patients who were treated with the nitrogen mustard (methyl-bis-β-chlorethyl-amino hydrochloride) also referred to as Dichloren. This drug was given by intravenous injection daily or on alternate days to children weighing less than 20 kg. in doses of 1 mg., and to those weighing more than 20 kg. in doses of 1.5 to 2 mg. until they had received a total dose of from 0.5 to 1 mg. per kilogram of body weight. During the subsequent maintenance therapy the children were given 1 or 2 mg. of the drug at 15-day intervals. This therapy usually induced regression of the disease process for 3 months, and occasionally a period of improvement lasted as long as 15 months. The first series of treatments always produced favorable effects, whereas the later series of injections were followed by shorter periods of improvement.

The authors feel that satisfactory results were obtained in the 10 patients. They found that the temperature generally falls and becomes normal within a week. The general condition improves, and the swelling of lymph nodes and the spleen usually subsides in the course of 15 days. The intervals between successive recurrences range from 3 to 15 months. Cortisone was found active in recurrences of 5 patients particularly when given together with antibiotics. Blood transfusions were given in the presence of severe anemia (hemoglobin level of less than 8 Gm. per 100 cc.). The nitrogen mustard (Dichloren) remained without effect during the third and fourth recurrences in 2 of the patients and in these irradiation therapy was carried out. Two other patients died during the third recurrence. The remaining 6 patients are alive and are in a good general condition. They are being kept under observation and are receiving maintenance therapy with nitrogen mustard. The development of leukopenia (leukocyte count less than 3,000 per cubic millimeter) and the development of anemia necessitates the interruption of the nitrogen mustard administration and requires blood transfusions and treatment with cortisone or antibiotics. Occasionally irradiation therapy will prove helpful in connection with chemotherapy. As regards the use of TEM (triethylene melamine) the authors feel that this drug has no advantages over the nitrogen mustard; in fact, it is less desirable because of its unfavorable secondary effects on the hematopoietic organs.

Acute Virus Infections of the Lower Respiratory Tract in Children and the Stevens-Johnson Syndrome. J. F. M. Hölscher. Nederl. tijdschr. geneesk. 102:1025-1029 (May 31) 1958 (In Dutch) [Amsterdam].

Virus pneumonia or "primary atypical pneumonia" does not have a uniform symptomatology. Virus diseases of the respiratory tract have been differentiated on the basis of serologic tests into the following subgroups: (1) primary atypical virus pneumonia with increased titer (higher than 64) for cold agglutinins; (2) atypical virus pneumonia with normal cold agglutinin titer (lower than 64) (this type includes the adenovirus group [APC-types 4 to 7]); (3) ornithosis and psittacosis, in which the Wassermann reaction may be positive, and the cold agglutinin titer is usually increased. In addition to these forms there are the forms that complicate such virus diseases as measles and influenza. The author presents observations on 14 children with virus pneumonia, in all of whom the cold agglutinin titer was higher than 64. This type of virus disease shows no complement fixation test to any of the known viruses. That it was a virus disease was proved by the fact that filtered tracheal irrigation fluid from the patients produced virus pneumonia in volunteers.

In 2 of the 14 children the virus pneumonia was complicated by the Stevens-Johnson syndrome, which is a combination of erythema exudativum multiforme with stomatitis and conjunctivitis, sometimes terminating in keratitis or panophthalmia; other authors noted in addition balantitis, vulvitis, urethritis, otitis media, laryngitis, bronchitis, and bronchopneumonia. The syndrome has been referred to as ectodermosis erosiva pluriorificialis, and it has been connected also with the names of Fiessinger-Baader, Rendu-Riessinger, and Behçet. After presenting the histories of the 2 children in whom the virus pneumonia was complicated by ectodermosis erosiva pluriorificialis the authors point out that it has been suggested that the 2 conditions have the same etiology, but in 1 of their 2 patients they gained the impression that a double infection existed, because the pneumonia rapidly responded to antibiotic therapy whereas the skin and mucosal lesions failed to react. Furthermore, it has been suggested recently that the Stevens-Johnson syndrome is caused by an adenovirus, which would suggest a double virus infection in the patients in whom virus pneumonia is complicated by this syndrome. A cough was observed in all but 1 of the 14 patients with virus pneumonia, elevation of the temperature in 11, and malaise, anorexia, and vomiting each were observed in a number of the children. Percussion revealed no abnormalities in 8 of the patients, but auscultation disclosed crepitating rhonchi in 13 patients. In 6 of the patients with physical signs of pneumonia no signs of infiltration could be detected roentgenologically. Whereas cold agglutinin titers were above normal in all 14 children, the Wassermann reaction was always negative.

Evolution of Leukemia in Children in the Course of Treatment. J. Chaptal, R. Jean, P. Izaron and others. Rev. españ. pediat. 14:161-178 (March-April) 1958 (In Spanish) [Saragossa].

The modern treatment of leukemia in children by adrenal hormones, drugs antagonistic to folic acid, and especially by 6-mercaptopurine changes the course of the disease in some patients. A total, *clinical, medullary, and hematological remission* of long duration occurs, in the course of which new lesions of lymphoblastic infiltration appear in the viscera and in the central nervous system. The visceral and neurological lesions may appear with or without relation to a recurrence of the disease. Forty children with leukemia were treated at the pediatric clinic of the Faculty of Medicine of Montpellier with cortisone and 6-mercaptopurine or aminopterine. Fresh lesions were located in the brain and meninges in 4 patients, in the testis in 3, in the mediastinum in 3, in the lungs in 3, and in the kidney in 1 patient. The cerebromeningeal lesions were the most frequent. They produced various syndromes such as: intracraneal hypertension with edema of the fundus of the eye, hypothalamic, and cerebellar symptoms, convulsions, mental disorders, and disorders of speech. The testicular lesions were bilateral in 1 case and unilateral in 2. The mediastinal lesions were unilateral in 2 patients and bilateral in 1. The pulmonary lesions were of the type of miliary tuberculosis or of a network pattern. In the patients with pulmonary lesions it was observed that the discontinuation of the treatment was followed by fever, which disappeared on the resumption of the treatment. Renal lesions occurred in only 1 patient. They were bilateral in the form of large lumbo-aortic tumors with hematuria appearing shortly before death. Mediastinal, pulmonary, and renal lesions were visualized roentgenologically. In none of these cases was an autopsy done. The authors conclude that leukemia is a disseminated disease. The lesions in the hemopoietic organs improve with the administration of antileukemic drugs. The remissions elicited by the treatment give the patient a period of survival during which the lesions in the extrahemopoietic organs, which are resistant to the treatment, follow an independent evolution. The appearance of neurological symptoms, roentgenologic signs of pulmonary or mediastinal infiltration of the testicular tumors in the course of a remission following antileukemic treatment are indications of the presence of visceral or neurological leukemia which call for antileukemic treatment in high doses of the usual drugs. The intraspinal route should be used in lesions of the nervous system.

UROLOGY

Bilateral Complete Ureteral Duplication. N. B. Powell and E. B. Powell. J. Internat. Coll. Surgeons 30:36-45 (July) 1958 [Chicago].

When complete ureteral duplication is present bilaterally there will be 4 kidneys, 4 ureters, and 4 orifices, the 2 major orifices being located in the normal position in the trigone draining the major or lower kidney. The minor ureter which emerges from the minor or superior kidney crosses the major ureter and usually enters the bladder medial and distal to the major orifice, although it may enter the posterior urethra, the ejaculatory duct of the male, and the cervix or vagina of the female. Ureteral anomalies predispose to urinary stasis, infection, and calculous disease. When anomalous ureteral and/or renal conditions are suspected an early accurate diagnosis can be made by retrograde pyelographic, cystographic, bulb ureteropyelographic investigation, and other specialized techniques available to urologists. Patients with ureteral duplication may have pain, either dull or sharp and intermittent or constant, which is located in the lower part of the abdomen, the flank, or the costovertebral area. In the event of stricture of the ureter, the ureteropyelogram will show the dilatation proximally and possibly the actual stricture. The completely duplicated ureter is usually constricted at the site of normal anatomic narrowing, while the incompletely duplicated ureter is frequently constricted at the point of juncture. Five new cases of bilateral complete ureteral duplication occurring in female patients are reported, nonobstructing stones being present in 1 case in each of the 4 intrarenal pelves.

Renal Papillary Necrosis: A Clinical Study of 34 Cases. N. Hultengren. Acta chir. scandinav. 155: 89-99 (No. 1-2) 1958 (In English) [Stockholm].

Thirty-four patients were hospitalized for renal papillary necrosis in the Urological Unit of Karolinska Sjukhuset in Stockholm, Sweden, from 1953 to 1957. All but 2 of the patients were women and only 2 (both women) had diabetes. No patient had chronic obstruction of the urinary tract. In 32 patients the renal papillary necrosis was classed as chronic. [In this connection the author points out that 129 of 211 cases of renal papillary necrosis reported before 1955 were accompanied by diabetes and 76 by urinary obstruction.] Five of the 34 patients died. Autopsy was performed in 3 cases. The diagnosis of renal papillary necrosis was made before admission to Karolinska Sjukhuset in 2 patients. The others were admitted with the diagnosis of recurrent cystopyelitis. The symptoms in most cases were the classical, pain and hematuria. Recurrent dysuria, pollakiuria, and pyrexia were also complained of. The diagnosis was made ante mortem in all patients but 1; in 27 the diagnostic method was excretion urography and in 3 pyelography. In 3 patients renal papillary necrosis was not diagnosed until after operation. The preoperative diagnoses were pyelonephritic shrunken kidney, "silent kidney," and lithiasis of the upper renal pole. In this last case renal papillary necrosis had been suspected from the roentgenograms.

Perhaps the most interesting finding was that headache or migraine was present in 29 of 31 patients for long periods before the renal symptoms appeared. Association between the headache and the renal disease appears probable. "Migraine equivalents" in the form of pain in the chest, abdomen, and extremities have been described, and it is therefore not inconceivable that changes in the renal circulation may also arise. Hypertension may be excluded as the cause of the headache, as the hypertension began late in the history of these patients and usually after the onset of the renal disease. Most of the patients had ingested large amounts of analgetics for the relief of headache before the renal disease appeared, particularly agents containing Phenacetin. However, in cases of poisoning with this drug the renal lesions were of interstitial nephritic type. Treatment was directed against urinary infection. Stones and shed papillae causing obstruction were surgically removed when this was indicated, and blood transfusions were given for the anemia which was present in almost all of the patients. These measures retarded the course of the disease, but in no case did the lesions completely heal. While heminephrectomy or nephrectomy have been recommended by some for the treatment of unilateral renal papillary necrosis, the authors issue a stern warning against nephrectomy, since contralateral lesions may develop after a very short time.

Tantalum 182 in the Treatment of Bladder Tumours. G. Jönsson, B. Månsson and L. Röhl. Acta chir. scandinav. 115:111-119 (No. 1-2) 1958 (In English) [Stockholm].

Tumors of the bladder have been treated in the Urologic Unit of the Department of Surgery of the University of Lund, Sweden, by combined surgery and radiotherapy. External irradiation, because of several drawbacks, was replaced by implantation therapy in 1940. Electroresection or partial or total cystectomy were combined with implantation of radium needles in patients with bladder tumors treated between 1940 and 1955. Since May, 1955, the authors used radioactive tantalum (Ta^{182}) instead of radium needles. Ta^{182} is produced by neutron irradiation of Ta^{181}. It has a half-life of 111 days. The beta rays of the tantalum needles are filtered off with a surface layer of platinum. The tantalum wire itself has a diameter of 0.2 mm. The thickness of the covering platinum layer is 0.1 mm., so that the total diameter of the needle is 0.4 mm. The tantalum needles, which are 12.5 cm. long, generally have an activity of 12 to 13 mc. each when delivered from the reactor, corresponding to about 1 mc. Ta^{182} per linear centimeter. The needles can be used until the activity is reduced to about 5 mc. The treatment periods ranged from 3 days with a dose of 4,620 r to 15 days with 8,300 r. As a rule treatment was given for 5 to 8 days and the dose then was 5,500 to 6,500 r. Ta^{182} was used in 63 patients with bladder tumors.

Benign, large papilloma was present in 21 and solitary carcinoma in 42 patients. Ta^{182} was implanted intravesically in all cases, usually in combination with partial cystectomy. Malignancy was ascertained by cystoscopy, urography, urethrocystography, and bimanual palpation. Preoperative biopsy was seldom performed as the procedure involves risk of implantation metastases. There were no deaths attributable to surgery. The postoperative irradiation reactions in the bladder and the subjective reactions were brief and mild in the patients with benign papilloma. No recurrence appeared during follow-up in this group. For these reasons it is considered justifiable to perform such a radical operation as partial cystectomy plus implantation of Ta^{182} even in benign, large papillomas. The 10 late deaths (all in the cancer groups) almost all occurred in patients with perivesical extension of cancer at the time of operation. Partial cystectomy with Ta^{182} implantation should therefore be reserved for tumors which have not infiltrated through the bladder wall.

Management of the Undescended Testis. J. Brunet, R. R. De Mowbray and P. M. F. Bishop. Brit. M. J. 2:1367-1371 (June 14) 1958 [London].

The authors present a follow-up study of 209 patients with undescended testes, referring in particular to the prognosis regarding fertility. Age at the time of treatment varied between 5 and 20 years. Most of the patients were treated before puberty, but 3 received treatment at the age of 14, 2 of whom are sterile. The third patient had extracanalicular testes and spermatogenesis was preserved. Another patient treated at the age of 20 is married and has a child. The cases are classified according to the position of the testis: (1) canalicular, (2) extracanalicular, (3) retractile, superficial inguinal, and (5) impalpable. Patients in whom the spermatic cords were thought to be too short to allow normal testicular descent were treated with chorionic gonadotrophin. The total dose ranged from 260 to 40,000 I. U., with an average of approximately 12,000; the dose at each injection ranged from 100 to 1,500 units and was most commonly 500 units. The duration of treatment varied from 1 to 12 months with an average of 4 months. The ideal age for treatment is thought to be 9 or 10 years. Patients were treated surgically if there was evidence of mechanical obstruction to the descent of the testis or of deviation to the superficial inguinal pouch or to another ectopic position or if endocrine therapy had failed.

Results show that spontaneous descent occurred in 35 of the 209 patients, 20 of whom had retractile testes. In 110 of 193 patients descent occurred following treatment with chorionic gonadotrophin, which acts by lengthening the spermatic cord and cannot rectify a mechanical abnormality, whereby a testis has migrated into the wrong position. Descent occurred in 111 of 120 patients who received surgical treatment. A completely satisfactory result (normal position, size, and consistency) was obtained in 65%, i. e., 78 of 120 patients, of the surgically treated patients who were followed up. In 6 of 26 patients with impalpable testes complete descent occurred under the influence of chorionic gonadotrophin, while in 7 of 15 patients with impalpable testes, the testes were placed in the scrotum at operation.

The results of treatment with regard to subsequent androgenic development are excellent. In only 3 of 209 patients was there any gross degree of testicular deficiency. The result with regard to fertility of the unilateral cases show that 93%, i. e., 27 of 29 patients exhibited normal fertility, and 17 of 24 patients with bilateral undescended testes are fertile, evidence for the remaining 4 depending solely on the fact that the patient had achieved paternity. Of the 19 fertile patients in the group of the 24 with bilateral undescended testes 14 were treated with chorionic gonadotrophin alone while 5 were subsequently operated on. The remaining 5 patients were found to have a subnormal sperm count, 2 patients had complete aspermia and 3 had sperm counts less than 20 millions per milliliter and a motility of less than 1.5. There is no evidence that chorionic gonadotrophin in moderate dosage can cause permanent damage to the seminiferous tubules. Orchiopexy is the treatment of choice when there is a mechanical defect or when chorionic gonadotrophin therapy fails.

INDUSTRIAL MEDICINE

Cardiac Rehabilitation: A Survey of Cardiologists' Opinions. B. Williams, P. D. White, P. R. Lee and H. A. Rusk. Am. Heart J. 56:107-111 (July) 1958 [St. Louis].

As part of a national survey of cardiac rehabilitation, sponsored by the National Heart Institute, a questionnaire was sent to a number of the nation's leading cardiologists and internists who have had broad experience in cardiology, asking their definition of the term, their opinions as to how rehabilitation of the patient with cardiac disease is most effectively accomplished, as well as what future course should be taken in assuring the cardiac patient of his place as an effective member of society. The opinions of 36 of these physicians are analyzed in this paper. Most definitions stressed the restoration of the patients to a useful and happy life, within the limits of their physical capacities. Almost all agreed that a careful, sympathetic, and, particularly, an unhurried discussion with the patient regarding the nature of his heart disease is the first and most valuable procedure in cardiac rehabilitation. This should begin early in the course of the illness and should be continued during all subsequent interviews. The proper medical treatment and the importance of the elimination of fear regarding heart disease were stressed. After recovery the patient should have a trial at his usual occupation with as few modifications as possible. Consultation with persons trained in related fields, such as social service or vocational counseling, was thought to be helpful, but several doctors expressed disappointment with their experiences in such consultation. Certain customs and laws with respect to disability, compensation, and decision of unemployability by various industries require correction.

The group of patients with congenital heart disease was felt to hold the most promise of cardiac rehabilitation, because so many lesions are correctible or, at least, improvable by surgery. Rehabilitation of patients with rheumatic heart disease was thought to be largely dependent on the severity of the active rheumatic fever, degree of valvular deformity, and presence or absence of accompanying congestive failure. Great help has come from surgical correction of mitral stenosis. It was felt that most patients with hypertensive cardiovascular disease could carry on active, useful lives, particularly with the aid of modern drug therapy. It was emphasized that the majority of patients do recover from myocardial infarction to a sufficient degree to return to their previous work with little or no modification in their activities. In patients with cerebral vascular disease the best results were obtained from the help afforded by special rehabilitation centers and techniques. There was much enthusiasm for the great advances in treating patients who have had "strokes." Patients with neurocirculatory asthenia were thought to be the most difficult group of all to handle. Emphasis should be put on the longevity of individuals with neurocirculatory asthenia and the fact that they often "outgrow" some of their difficulty as they adjust themselves to their problems.

Chronic Silo Filler's Disease. H. W. Schell. Connecticut M. J. 22:546-552 (July) 1958 [New Haven, Conn.].

Silo filler's disease or silage gas poisoning has been observed in agricultural workers. A 64-year-old farmer was observed who in December, 1956, complained of progressive shortness of breath of 5 months' duration. In the middle of July he began to fill his silo with green grass hay. After each load of hay was placed in the silo, sodium metabisulfite was added as a preservative. In the late summer of 1956 drought conditions prevailed and environmental temperatures were high. Small amounts of hay were put into the silo frequently. The patient entered the silo about every second day and stayed from 1 to 20 minutes at a time from the middle of July until September. He noted repeatedly a "brownish" haze immediately over the silage. He developed a dry hacking cough after exposure to the gases. The cough and feeling of suffocation increased in severity. The cough became productive of whitish sputum. The sputum became more copious and yellow in color, and cough and dyspnea continued to increase. He was seen by his private physician who administered antibiotic therapy but there was no lessening of cough or of shortness of breath.

This case is thought to represent chronic silo filler's disease, caused by repeated inhalation of nitrogen dioxide, and which differs in its clinical course from previously described acute and subacute cases. Adrenal cortical steroid therapy was used later with apparent benefit. It is suggested that toxic oxides of nitrogen are formed over hay silage, as well as over corn silage, under conditions of drought and high temperature. Previously reported cases occurred in patients who were exposed to silo gases within about 1 week of the time that the silos were filled with corn. In 3 of the 8 reported cases, the patients described a yellow to brownish gas or haze immediately above the silage and in 5 cases an acrid, ammonia-like or "bleach-like" odor was noted. Cough and dyspnea were common symptoms. Patients who were not rendered unconscious, with death ensuing in a matter of hours, seemed to recover with a remarkable relief of symptoms, only to become acutely ill once again with a recurrence and intensification of symptoms several weeks after the initial exposure.

The case presented was unique in that it followed neither an acute fatal course nor a subacute "saddle-back" course. It is suggested that the course of the illness in this instance represents the development of a progressive pulmonary granulomatous process which was eventually halted and reversed by prednisone, leaving a faint fibrotic residual visible on the x-ray film. It has been suggested that repeated exposure to toxic silage gases might be a factor in the pulmonary interstitial fibrosis seen in farmers.

Studies on the Epidemiology of Furunculosis in Miners. A. C. Ruys, H. Beeuwkes, K. R. Koopmans and J. S. Mulder. Trop. & Geog. Med. 10:142-148 (June) 1958 (In English) [Amsterdam].

Furunculosis occurs more frequently in miners than in the average population and more in underground workers than in those who work on the surface. Various factors may account for this. Mining work may involve a lowering of resistance, by which the commensal staphylococci sooner exert a pathogenic effect than they would in other persons. The daily intensive cleansing necessary to remove the coal dust may be a factor in this lowering of the resistance. Certain virulent types of staphylococci may spread as the result of close contacts in common washrooms. Furthermore, attendance at dressing stations, where antibiotics are administered, might promote dissemination of resistant, aggressive strains. Phage typing having produced a possibility of studying these problems, the authors used this method on 753 Staphylococcus strains from furuncles in miners. Phage typing revealed very few differences in the distribution of strains over various types and groups in a number of mines and subsidiary industries; nor did the distribution differ from that among other groups of people.

Resistance to penicillin was observed in 23.1% of the strains from furuncles. The resistant strains belonged mostly to phage group 1. The penicillin resistant strains were distributed over the mines in about the same proportion as the sensitive strains. The noses were inspected for the presence of staphylcocci in 131 healthy miners, in 85 miners with furuncles, and in 129 family members of the latter. The results suggest that furunculosis in miners should not be attributed to increased circulation or particular aggressiveness of the staphylococci. The question remains whether the cause lies in the lowered resistance of the skin.

THERAPEUTICS

Experiences with E-39 in the Treatment of Advanced Malignant Neoplasms. A. Brunschwig. Cancer 11:765-768 (July-Aug.) 1958 [Philadelphia].

The compound 2,5 di-propyloxy-3,6-di-ethyleniminobenzoquinone (E-39) was administered intravenously to 40 patients with various forms of advanced cancer, a large percentage of which were ovarian in origin. There were positive responses in 2 of the 5 patients with advanced cancer of the colon, and 7 positive responses among the 13 patients with ovarian cancer. While no instance of complete regression of advanced cancer with rapid restitution of the individual to normal or near normal status was observed, evidence was forthcoming to the effect that E-39 was active in causing temporary restraint of growth and regression of malignant neoplasms in 13 of the 40 patients treated. The use of this preparation is not unattended with certain risk. Depression of the circulating leukocyte and platelet levels, with purpura in a few instances and gastrointestinal hemorrhage in 1 case, was observed.

Long-Term Treatment of Arthritis with Mepacrine and Chloroquine. F. Erlendsson. Ugesk. læger 120:793-799 (June 19) 1958 (In Danish) [Copenhagen].

The antimalarial compounds mepacrine and chloroquine have an antirheumatic effect which can be advantageously utilized in the treatment of rheumatic arthritis. In most of the 14 patients with rheumatoid arthritis treatment with these agents was started over 4 years ago. In 3 cases treatment was terminated for various reasons after less than a month; 1 patient was cured in 3 weeks; and in 1 case treatment was discontinued after 62 days because of a pruriginous exanthem, and in 1 case, after 162 days because of cardialgia. The addition of vitamin A has since proved useful in the treatment of cardialgic disturbances and seems able to support the favorable antirheumatic effect of the substances named. Eight patients reacted satisfactorily to the treatment. Of these 1 patient has moved away, 1 died from bronchopneumonia at the age of 82 after 37 months' treatment, and 1, treated for 44 months, is hospitalized because of a complicated fracture of the thigh. Treatment is being continued with good effect in 5 patients, with total time of treatment of up to 4 years and 2 months. In 2 patients with strongly active rheumatoid arthritis in an advanced stage, unsuccessfully treated with cortisone, remarkable improvement followed on continuous treatment with chloroquine or mepacrine for 2 and 2¾ years respectively.

Chloroquine Treatment of 20 Patients with Active Rheumatoid Arthritis. F. Erlendsson. Ugesk. læger 120:800-804 (June 19) 1958 (In Danish) [Copenhagen].

Chloroquine exerts a favorable effect in many cases of rheumatoid arthritis. The treatment is more easily carried out than sanocrysin treatment; is not, on individualized dosage, accompanied by more side-effects than gold treatment; and is less expensive than steroid treatment, to which it has in cases proved superior. Chloroquine should be tried when treatment with cortisone and prednisone does not avail. The patients should be under regular control, preferably by the same person, during the entire period of treatment. The latent time for the antirheumatic effect of chloroquine varies greatly; the effect, possibly accompanied by unpleasant side-effects, may in some cases appear after a few days' treatment, and in others is not seen till after up to 2 months' intensive medication. Ambulant treatment with chloroquine diphosphate for up to 2 years was given to 20 patients with active rheumatoid arthritis, with satisfactory results in 16. At the conclusion of the investigation 10 patients were under continued treatment, while 6 patients with up to 170 days' observation time maintained their improvement. Three patients treated unsuccessfully, 2 with cortisone and 1 patient with prednisone, improved under treatment with chloroquine. On the other hand, in 3 patients given chloroquine change to prednisone became necessary. One patient discontinued treatment with chloroquine because of sleeplessness during the treatment. Chloroquine is recommended for the treatment of rheumatoid arthritis, but the author cautions against stiff dosage and deficient control.

Allergic Reactions to Tranquilizing Drugs. L. E. Hollister. Ann. Int. Med. 49:17-29 (July) 1958 [Lancaster, Pa.]

Three classes of tranquilizing drugs, including the phenothiazine derivatives (notably chlorpromazine), the Rauwolfia alkaloids (notably reserpine), and the substituted propanediols or butanediols (notably meprobamate) have been widely used and allergic reactions to the first and third classes of these drugs have been of great importance. Sensitivity to chlorpromazine may be manifested by agranulocytosis, jaundice, dermatitis, and other minor reactions. Strong circumstantial evidence suggests that agranulocytosis from chlorpromazine is of immunological origin, though this contention remains to be proved. Chlorpromazine jaundice has been reproduced often enough by the challenge test to implicate drug allergy as the mechanism. Some cross-sensitivity may possibly exist between chlorpromazine and promazine, but it appears that it is uncommon and contingent on previous sensitization to chlorpromazine. Neither jaundice nor agranulocytosis has thus far been reported from proclorperazine and perphenazine, despite their increasing use. On the other hand, both agranulocytosis and jaundice have been reported from promazine and mepazine, as well as other phenothiazine derivatives not widely used. It appears that chlorination of the phenothiazine ring is not the critical determining factor in producing sensitivity. At present, it does seem that the introduction of the piperazine ring into the structure of these drugs increases the potency of these drugs (proclorperazine, perphenazine) and decreases their allergenic potential.

Reserpine barely qualifies as an allergen on the basis of the comparatively rare reports of untoward reactions. It does appear to have the potential of producing immunological thrombocytopenia. Aggravation of such allergic disorders as chronic urticaria, bronchial asthma, or atopic rhinitis might be expected from the parasympathomimetic action of the drug. Two case reports are presented which indicate that purpura may be produced by the drug.

Meprobamate sensitivity is manifested by fever, skin rashes, and constitutional signs, including vascular collapse. This sensitivity is peculiar in that it commonly is produced by the initial dose of the drug. The case of a 62-year-old man with schizophrenia is reported in whom an erythematous petechial rash associated with malaise and fever was observed after 2 doses of 400 mg. of meprobamate. No reactions occurred after the administration of a propanediol preparation, lacking the carbamic acid groups. This implies that the carbamate groups of the meprobamate molecule determine this type of sensitivity.

Diffuse Bacterial Peritonitis in Childhood and Intraperitoneal Therapy with Oxytetracycline and Tetracycline. F. Soave. Minerva chir. 13:573-576 (May 31) 1958 (In Italian) [Turin, Italy].

Fifty-seven children, aged 5 to 12 years, were treated with oxytetracycline and tetracycline administered intraperitoneally postoperatively. Diffuse purulent peritonitis, a result of perforation in acute appendicitis, was present in 30 children, acute appendicitis with abscess and circumscribed peritonitis in 17, and appendicitis accompanied by serofibrinous effusion in 10. Oxytetracycline therapy was used in 32 patients and tetracycline in 25 patients. The drug was instilled into the peritoneal cavity in a dose of 1 Gm. diluted in 20 cc. of cold physiological solution before the closure of the abdomen. The mixture of the instilled solution and pus was then drained. Subsequently the 2 antibiotics were instilled intraperitoneally in a daily dose of 1 Gm. through a small rubber catheter, which was introduced into the peritoneal cavity at the time of operation and kept in position for 72 hours. In few instances it was necessary to leave the catheter in position for 7 days. Each patient received a total dose of 3 Gm. of either drug, supplemented by 1 Gm. of vitamin C a day.

Oxytetracycline brought about a prompt response in 30 patients (96%), and tetracycline did likewise in 22 (89%). General state of health improved after 36 hours of chemotherapy. Fever subsided more quickly with oxytetracycline than with tetracycline. Supplementary administration of tetracycline by mouth restored the body temperature to normal whenever the intraperitoneal administration of the drugs alone was ineffective during the first 72 hours of chemotherapy. The drugs did not produce any toxic effect on the exposed tissue. Three general and 2 local complications attributable to the chemotherapy developed.

Reactions to Benzathine Penicillin. R. B. McFarland. New England J. Med. 259:62-65 (July 10) 1958 [Boston].

The author describes the reactions to benzathine penicillin G in 12,858 male Navy recruits who received this drug in the course of a mass prophylaxis program against streptococcic infection carried out at the United States Naval Training Center at Bainbridge, Md., during the winter and spring of 1956 to 1957. Recruits suspected of being allergic to penicillin were excluded. Two dosages of penicillin, 600,000 units and 1,200,000 units, were used. Reactions ranged all the way from mild urticaria, lasting 1 or 2 days, to the full picture of serum sickness, lasting several weeks. No reaction phenomena not previously described for penicillin were observed. A reaction rate of 1.3% (175 patients) was observed in this study of the 12,858 naval recruits receiving a single injection of this drug. Twenty-one per cent of the reactions were of minor severity; 67% were not severe enough to cause loss of time from work; but 8%, i. e., 1 of 1000 men injected had a reaction serious enough to require cortisone therapy. The reactions were of the delayed type and usually occurred 8 to 15 days after injection. Over 25% of the men with more severe reactions had intermittent symptoms more than 30 days after injection. There was no correlation of the interval between injection and reaction and the length or severity of the reaction.

Treatment early in the study consisted of oral administration of antihistamines, tripelennamine or diphenhydramine, and calamine lotion applied for itching. Later a controlled study was attempted with the use of promethazine and a placebo. Light duty or bed rest was prescribed when necessary. Cortisone was added only in the patients with more severe reactions, who failed to respond to bed rest. The effects of this therapy on the reactions may be summarized as follows: cortisone was effective in masking the symptoms; relapses were frequent and occurred after placebo or antihistamine therapy as well as after cortisone treatment. However, relapses did not occur in patients with urticaria as the only manifestation of their reaction. Rapid improvement and recovery occurred frequently in the group treated with placebos just as in the group treated with promethazine. When the number of days for which the patients in the 2 groups were reported sick were compared, it became evident that there might be a slight advantage to the promethazine therapy over the placebo. Antihistamine therapy did not have any effect in preventing relapses, but it appears to have a slight effect in diminishing the length of illness caused by the allergy to benzathine penicillin.

PATHOLOGY

The Hemophilic Syndrome: A Review of 27 Cases. J. W. Thomas, D. M. Whitelaw and W. H. Perry. Canad. M. A. J. 79:100-102 (July 15) 1958 [Toronto, Canada].

The authors examined 24 patients with antihemophilic globulin defect (A. H. G.) and 3 patients with Christmas factor defect in Vancouver between 1954 and 1957 in order to evaluate and correlate the results of the thromboplastin generation test and the new methods of assaying the A. H. G. defect with the clinical picture in patients with the hemophilic syndrome. Symptoms became apparent within the first year of life in 21 patients and 8 of them showed manifestations of the disease within the first week of life. The most common manifestations were severe and easy bruising followed by hemorrhage into joints and abnormal bleeding from cuts. The thromboplastin generation test performed on specimens obtained from all patients made differentiation between the 2 deficiencies, i. e., A. H. G. and Christmas factor, in all cases possible. The percentage of thromboplastin generated varied from 3 to 38%, with the exception of 1 patient with Christmas disease who showed 70% of normal generation. Greater dilution of the serum and mixing with serum obtained from a patient known to have Christmas disease clarified the diagnosis in this patient. The antihemophilic globulin assay was performed on 19 of the 24 patients with this defect, and the level of the factor varied between 0.1% and 6% of the normal.

The authors believe that the percentage of thromboplastin generated, although it did not correlate well with the severity of the disease, is of the greatest value in the diagnosis and differentiation of hemophilic disorders; should the routine dilutions in this test fail to show a defect, greater dilutions might be used and compared with the normal control at a similar dilution. The antihemophilic globulin assay correlated well with the severity of symptoms of the patients in whom the assay revealed a level of 1.5% or greater. Some difficulty of correlation between severity of symptoms and A. H. G. assay was found in those with a level lower than 1.5%. Administration of fresh frozen plasma appears to be a satisfactory form of therapy for the uncomplicated hemorrhagic attacks of most of these patients. No complications of or refractoriness to this therapy have been noted up to the present time.

Dupuytren's Contractors with Special Reference to Pathology. R. D. Larsen and J. L. Posch. J. Bone & Joint Surg. 40A:773-792 and 832 (July) 1958 [*Boston*].

These observations are based on 99 patients with Dupuytren's contracture. There were 79 men and 20 women, a ratio of approximately 4:1. In most previously reported series the ratio has been about 8:1. In 46 of the patients both hands were involved. The authors mention some forms of nonsurgical treatment, pointing out that most of them have proved ineffective. They treated 3 patients with alpha-tocopherol but felt that while there was a temporary softening of the contracture, the progressive course of the disease was not altered. They had no experience with hydrocortisone nor with irradiation therapy. Surgical treatment was employed by the authors on 74 (89 hands) of their 99 patients. The average duration of the symptoms before surgical intervention was 4.6 years. The ages of the patients ranged from 12 to 78 years.

The authors refrained from blind or subcutaneous fasciotomy since they feared injury to the digital nerves in the palm. They performed radical or total excision of the palmar fascia on 64 of the hands; partial fasciectomy, in 20; definitive fasciotomy, in 2; and preliminary fasciotomy, in 3. In 2 patients excision of a finger nodule only was done. In 8 patients skin-grafting of the wound was necessary because the contracture had irreparably damaged the overlying skin. Contracted bands and nodules of diseased fascia in the fingers were removed through appropriate incisions. Excellent results were obtained in 52 hands, good results in 22, fair in 5, and poor in 5.

On the basis of histological studies of specimens from 61 patients, the authors conclude that Dupuytren's contracture is a fibrous-tissue proliferation arising within the palmar fascia in intimate association with thick-walled vessels together with an increase in capillary vascularity. This tissue undergoes the well-known stages of maturation of fibrous tissue until a firm, relatively avascular, contracted scar is formed. The pathological changes do not suggest that the lesion is due to trauma, inflammation, or neoplasm. Further study is needed to determine the significance of iron pigment in the early lesions. Surgery is the only form of treatment which will produce any lasting benefit in this disease.

On the Specific Pathogen of Rheumatism. G. D. Zalessky, N. N. Vorobieva, O. I. Pirogova and others. Terapevticheskiy Arkhiv 5:3-15 (No. 5) 1958 (In Russian) [Moscow].

Zalessky and his associates succeeded in isolating cytopathogenic viruses from the blood, throat washings, and verrucous formations upon the heart valves of patients with rheumatic fever, utilizing connective tissue cell cultures. All of the isolated viruses were related in their antigen structure. They do not possess hemagglutinating capacity and they do not manifest cytopathogenic effect on the cultures of human malignant cells. Antibodies were found in the blood of the patients with rheumatic fever and these antibodies had a neutralizing effect upon the isolated viruses. The titer of antibodies in the course of the rheumatic fever disease increases slowly. Infection of rabbits with the viruses produced in a course of 15 to 45 days valvular lesions of the heart in 40% of experimental animals, predominantly of the mitral valve. A focal interstitial myocarditis was found in 60% of the experimental animals. A picture of disorganization of the basal substance of the connective tissue with edema and accumulation of acid mucopolysaccharides were strikingly manifested in the focal lesions, particularly in the leaflets of the mitral valve. In 5 of the infected rabbits autopsied 65 days after the infection with virus, there was found pronounced ulcerations of the mitral valve of sclerotic character with deformation analogous in its pathological picture to that observed in rheumatic fever in man.

Papilloma of the Large Intestine: A Clinical-Pathologic Correlation. M. B. Goldgraber and J. B. Kirsner. Gastroenterology 35:36-49 (July) 1958 [Baltimore].

The authors report on 3 men and 1 woman, between the ages of 52 and 76 years, with papilloma of the large intestine associated with a copious mucous discharge from the rectum. The clinical pattern in these patients showed a wide range from that of an asymptomatic tumor detected accidentally at a routine roentgenologic examination to that of a rapidly fatal disease with death being caused by a profound electrolyte imbalance. Roentgenologic examination of the first patient revealed marked deformity of the duodenal bulb and a shallow crater at the apex. There was a filling defect, about 3 by 2 cm. in size, in the transverse colon near the hepatic flexure. Thirty centimeters of transverse colon were resected and an end-to-end anastomosis was performed. At microscopic examination of the operative specimen the small lesion was found to be an adenomatous polyp. The larger sessile lesion was a papillomatous growth with atypia. The patient recovered and continued to be well on a modified ulcer program. The high colonic site of the tumor made of the relatively small size villous papilloma rather a rarity. The association with an adenomatous polyp elsewhere in the colon was reported by other workers. In the second patient, the villous tumor was of the pedunculated variety, with a pedicle 1 cm. long. The papilloma secreted profusely and the rectal discharges were copious. Mucous secretion in villous tumors is caused by an increase of the secreting surface, with huge numbers of goblet cells. Continuous outpouring of fluid from the large villous surface may lead to inanition and subnutritional states. The patient's symptoms such as weakness, dizziness, tinnitus, and blurred vision were interpreted as expressions of psychoneurotic personality, but probably were caused by electrolyte unbalance. There was an associated adenocarcinoma 7 cm. above the villous tumor.

The third patient passed large amounts of watery stools and proctoscopy revealed a polypoid area in the rectal mucosa, 12 cm. above the anal orifice. Abdominal operation showed a right mass in the sigmoid colon. Eight inches of the tumor-bearing intestine were resected and end-to-end anastomosis was performed; a colostomy also was carried out. The mucosa was replaced by papillomatous tissue, consisting of shaggy, villous projections 1 cm. long; 2 cm. from the excision border there was an area with superficial ulceration with uprolled edges and, microscopically, some submucosal infiltration. Twelve years later the patient was readmitted with a history of 4 to 5 years' duration of watery stools, and weight loss. He had fainting spells, postural hypotension, a wrinkled skin, and rapid pulse. Quantitative measurements of sodium and chloride secretion in the urine and in the rectal discharge showed a minimal urinary output of sodium chloride, as in severe salt depletion, and a high salt loss in the rectal discharges. An abdominoperineal resection, with an end colostomy, was performed. The gross specimen contained a soft, papillary, friable mass, and at 12 cm. from the proximal end of the specimen a polypoid, stalked tumor was found. Microscopically the main tumor was found to be a mucosecretory adenocarcinoma composed of large papillary folds. The patient recovered and the resection of the secreting tumor was followed by a return of blood chemistry to normal. Electrolyte imbalance also was the major complication in the 4th patient who had signs of dehydration, with hemoconcentration, associated with a more definite hyponatremia, hypochloremia, and azotemia. There was a severe circulatory collapse on the 4th day after admission and he died on the 7th day. Autopsy revealed a villous papillomatous growth with no invasion of the submucosa. There was a latent carcinoma of the prostate which had not metastasized. The patient's death was not caused by this carcinoma, but seemed attributable to a disturbance in the serum electrolytes.

Papillomas of the large bowel, although uncommon, are not rare and may be associated with neoplastic changes. The diagnosis of papilloma of the rectum may be difficult because of the softness of the tumor and the vagueness of the symptoms. Excessive secretion from papillomas may result in serious depletion of the extracellular sodium and chloride; the electrolytic imbalance may be fatal. Careful studies of the serum, urine, and, at times, the fecal concentrations of electrolytes are indicated in patients with papillomas of the large intestine and rectum.

The Syndrome of Dextroversion of the Heart. R. P. Grant. Circulation 18:25-36 (July) 1958 [New York].

Three cases of dextroversion and an analysis of 116 additional cases collected from the literature are presented by the author. There are 3 major differences between dextroversion and mirror-image dextrocardia. 1. In dextroversion the atria have a normal position but the ventricular heart lies rightward; there is also a 90 degree counterclockwise rotation of the ventricular heart on its long axis, with the right ventricle lying superiorly to the left ventricle. In contrast with this, in mirror-image dextrocardia all cardiac structures are rightward mirror-images of the normal heart. 2. The vast majority of cases of dextroversion (90%, i.e., 62 of 69 patients studied at autopsy) have additional intracardiac malformations, usually of the conotruncal region, while in mirror-image dextrocardia additional intracardiac anomalies are probably no more frequent than in the population at large. 3. An abdominal heterotaxy is often present in dextroversion, which is different from the situs inversus that accompanies mirror-image dextrocardia: instead of inversion of abdominal organs there is a tendency for abdominal structures to be primitive and bilaterally symmetric, frequently with congenital absence of the spleen.

Dextroversion is a part of a potentially multiorgan developmental defect that takes place at a very early fetal stage. Depending on the intensity and distribution of the abnormality, a wide variety of intracardiac and extracardiac anomalies and combination of anomalies may result of which dextroversion of the heart is perhaps only one part. Transposition of the great vessels is present in over 80% (i.e., 95 of 119 cases of dextroversion) and may partly be due to the fact that in the presence of dextroversion a normal descent of the truncal septum often produces a severer functional abnormality than does transposition and these cases do not usually survive the earliest fetal stages.

Pathology of a Lower Esophageal Ring: Report of a Case, with Autopsy, Observed for Nine Years. H. E. MacMahon, R. Schatzki and J. E. Gary. New England J. Med. 259:1-7 (July 3) 1958 [Boston].

The authors describe a lesion found at autopsy at the junction of the esophagus and stomach in a patient 58 years of age. The lesion presented a classical lower esophageal ring for more than 9 years, during which time rotengenologic diagnosis was established and was repeatedly confirmed. The lesion, appearing roentgenologically as a narrow, deep, annular indentation in the lumen of a distended lower esophagus, was found at the junction of the esophageal and gastric mucosa. It appeared as a nearly symmetrical, circular, wedge-shaped shelf or diaphragm that protruded from the wall into the lumen in a plane that was almost vertical to the long axis of the esophagus. It represented little more than a mucosa fold covered above by squamous-cell mucosa and below by gastric mucosa. A delicate annular ring of smooth muscle encircled this fold immediately beneath the epithelium covering the innermost free margin. Anatomic studies showed the ring to represent the junction of esophagus and stomach, and since the ring was seen to lie 3 cm. above the diaphragm, it appears that a corresponding piece of stomach must have been herniated through the hiatus; it also appears that a ring is always associated with a hiatus hernia which causes transient narrowing of the esophagus immediately above the stomach. Although an anatomic sphincter is not demonstrable, its presence has been postulated for many years, particularly by radiologists, who frequently saw a sphincter-like transient contraction of the esophagus immediately above the herniated stomach. The physiologic sphincter differs in several respects from the ring. The sphincter extends over a greater length of the esophagus than the ring; it is less constant in a given case; and it does not show the sharply localized lack of distensibility of the ring. It acts like an active sphincter whereas the ring behaves like a passive structure. The ring may cause dysphagia and the physiologic sphincter does not. It is not known how the ring originates or what the relationship, if any, is to the physiologic sphincter. The anatomic construction of the ring, as revealed in this case, suggests that an interruption or break in its continuity, such as might be done by bouginage or by the use of the Mosher bag, would lead to an appreciable dilatation, and one might expect bleeding from such a simple procedure to be minimal.

Nasal Carriage of Staphylococcus Aureus by Nurses. M. E. M. Thompson and W. A. Gillespie. J. Path. & Bact. 75:351-355 (April) 1958 [Edinburgh].

Many nurses become nasal carriers of antibiotic-resistant staphylococci. The authors made studies to compare the rates of acquisition of staphylococci by nurses on medical and surgical wards, to investigate the effect of wearing masks, and to determine whether different strains of staphylococci varied in their ability to persist in the noses of these attendants. Studies were made on 4 groups of student nurses. Nose swabs, moistened with sterile saline solution, were taken when the nurses arrived from the preliminary training school, and subsequently every week for 12 weeks. A few nurses were found on arrival to be nasal carriers of penicillin-resistant staphylococci and were excluded from the experiments. Most of them had worked previously in other hospitals. Some nurses dropped out because of illness, leaving 92 who stayed in the experiment. It was found that nurses who wore masks continuously on the wards acquired nasal staphylococci more slowly than those who did not wear masks. Nurses acquired nasal staphylococci almost as quickly on medical as on surgical wards. Staphylococci, phage group 3, predominated on the wards and in the nasal swabs of nurses who worked there, but group-1 strains, although less numerous, persisted longer than group-3 strains in the noses of those who acquired them and more often caused persistent nasal carriage.

Atherosclerosis in Rhesus Monkeys: I. Hypercholesteremia Induced by Dietary Fat and Cholesterol. G. E. Cox, C. B. Taylor, L. G. Cox and M. A. Counts. A. M. A. Arch. Path. 66:32-52 (July) 1958 [Chicago].

The authors present data on blood lipids obtained from 30 adult rhesus monkeys which were subjected to various fat-containing diets for periods of several months to 3 years. It was found to be difficult, but essential, to present the fat diet in a form palatable to monkeys. An effective diet was developed, with use of a commercial ground monkey food (stock diet no. 2) as the basic ration, to which were added supplements of butter and cholesterol. A 1-food-1-meal-per-day technique was found useful. The experimental fat-containing diet was prepared to contain all nutritional requirements, and almost no other food was given to the experimental animals. This helped to insure ingestion of the fat and prevented the animals from subsisting solely on fruit rations. With use of this feeding technique the development of significant hypercholesteremia in most monkeys became relatively easy. Total serum cholesterol levels of 300 to 600 mg.% developed in 1 to 3 months in the majority of animals that were adequately tested.

The hypercholesteremic responses varied, some animals showing a "low" susceptibility to diet-induced hypercholesteremia and a moderate number showing either "moderate" or "high" susceptibility. These variations in response to dietary fat are comparable to the variations clinically observable in human subjects. The hypercholesteremia is interpreted as due chiefly to the excess of dietary cholesterol, rather than to the excess of dietary neutral fat. The authors favor this interpretation because (*a*) the serum neutral fat was usually normal or slightly subnormal, even in animals with marked hypercholesteremia, and (*b*) in preliminary studies, dietary fat alone, without cholesterol, produced no significant hypercholesteremia. Grossly and microscopically visible atherosclerosis developed in most animals subjected to moderate (300 to 500 mg.%) or high (over 500 mg.%) hypercholesteremia for a period of several months or longer. In the same or similar animals, intimal lipid deposition was accelerated by subjecting segments of the vessel wall to transient freezing injury. In an addendum to this paper the authors present evidence supporting the direct relationship of dietary cholesterol to serum cholesterol, an excess of the former inducing an excess of the latter, with only a secondary role assigned to dietary neutral fat or fatty acids.

The Effects of Hormones upon Hepatic Glycogenesis. J. H. Fodden. A. M. A. Arch. Path. 66:10-22 (July) 1958 [Chicago].

The adrenal cortical glycosteroids participate in hepatic glycogenesis. The 11-oxycorticosteroids have even been referred to as the "glycogenic hormone." This property of the steroids assumed importance during the examination of the effect of glycogenolytic agents upon carbohydrate "turnover" rates in tissue slices from animals prepared to saturation with these hormones. The relationship of insulin to this steroid function was investigated on Sprague-Dawley strain male rats made diabetic by the subcutaneous injection of alloxan. Those with a high glycosuria and polyuria of several weeks' duration were starved for 30 hours. A large group of normal and diabetic rats was fed Purina Chow ad libitum throughout the period of observation. A duplicate normal and diabetic group was maintained by force-feeding a high-carbohydrate diet. Cortisone acetate was given to approximately half the number of animals, normal and diabetic, in both groups. Other diabetic rats, chosen from the free-feeding group, received daily injections of protamine zinc insulin, either alone or concomitantly with injections of cortisone acetate. A third series of normal and diabetic animals was maintained under starving conditions for 48 hours. Hydrocortisone was given by intramuscular injection to all but the control animals throughout this period. Finally, a smaller colony of partially depancreatized rats was force-fed the high carbohydrate diet during both a control and a lengthy cortisone-administration period. Multiple liver samples were obtained from all animals after decapitation. Similar studies were made on mongrel dogs.

Augmentation of glycogenesis by the administered corticosteroids was obtained only in the presence of insulin, of either endogenous or exogenous origin. The insulin-inadequate animal was incapable of this response. Only with this qualification can the glucosteroids be considered as hepatoglycogenic. A prominent degree of glycogenesis was possible under circumstances in which insulin supply or its functional efficiency was reduced.

Glycogenic needs are satisfied in the presence of manifestations of "somatic" insulin inadequacy. With absolute insulin inadequacy, liver glycogen values, with 1 exception, are below the normal for the particular circumstance; they cannot be elevated by either food or glycogenic stimuli to a degree resembling that of the insulin-adequate organism. Starvation introduces the exceptional feature, when it may appear that the diabetic has glycogen values equal to and exceeding some of the values of a normal organism during dietetic insufficiency. This must be an additional expression of the diabetic's ability to retain a "basal" value of glycogen throughout extremes of feeding or starving; it is the normal organism whose glycogen values are responsive to changes. One wonders whether these latter have been considered in the estimation of normal human hepatic glycogen. Although there is resistance to exogenous insulin in steroid diabetes, it is not known whether the islets themselves are secreting subnormal, normal, or supernormal quantities. Nevertheless, diabetes of this origin can presumably be regarded as a relative insulin inadequacy, either quantitative or functional. The latter concept implies a poorly understood chemical inhibition or antagonism, and the former, an exhausted secretory capacity of normal islet tissues under intense steroid overactivity or their actual numerical reduction. Clinical evidence suggests that where the "functional reserve" of the insulin-producing mechanism is depleted, a more intense form of diabetes is elicited in the presence of an excess of adrenal glucosteroids.

Study of Clinico-Instrumental Techniques and of Serum Analysis of a Large Group of Presenile and Senile Patients with Cardio-Aortic Atherosclerosis. M. Rosselli, A. Lordi and P. L. Malfanti. Sett. med. 46:139-145 (April 15) 1958 (In Italian) [Florence, Italy].

Pathological patterns recorded by instrumental techniques and by serum analysis were studied in a group of 210 patients with cardio-aortic disease, 148 of whom were men and 62 women. The patients were selected on the basis of their age and on absence of hypertensive, rheumatic, or congenital disorder. There were 136 patients in the presenile group and 78 patients in the senile group, with the age of 60 being the dividing line. Aortic fluoroscopy revealed pathological changes in 63 patients of the presenile group (63%) and in 74 patients of the senile group (95%); there was no significant difference in incidence of the disorders between men and women. Electrocardiograms showed approximately the same incidence of pathological changes in the presenile as in the senile group (mean average 40%) and no wide difference between the 2 sexes. Elevated serum cholesterol level was more frequent among the patients of the presenile group (mean average 67%) than among the patients of the senile group (mean average 34%). There was no significant difference in the incidence of this disorder between the 2 sexes. A higher incidence of pathological changes in the serum lipoprotein was observed in the presenile group (mean average 80%) than in the senile group (41%); it was more frequent among men in the presenile group and among women in the senile group than in the respective counterparts. The incidence of serum phospholipids level was alike in the 2 age groups and in the 2 sexes. The incidence of serum heparin level was alike among women of the 2 age groups; but it was higher among men in the presenile than in men of the senile group.

Fluoroscopy and serum analyses applied in this series of patients were more sensitive methods than electrocardiograms for recording pathological changes of cardio-aortic atherosclerotic nature. Serum analyses were more sensitive procedures in recording the same pathological changes than instrumental techniques. This observation can be partly explained by the fact that pathological changes in the serum of patients with cardio-aortic atherosclerosis start at the age of 45, extending until the age of 65, and then suddenly start to decrease in frequency. Fluoroscopic changes of the aorta, however, begin to appear at the age of 55 and then gradually increase with the advancing age of the patient.

Histologic Studies of Kidney Biopsy Specimens from Patients with Hypertension. S. C. Sommers, A. S. Relman and R. H. Smithwick. Am. J. Path. 34:685-716 (July-Aug.) 1958 [Ann Arbor, Mich.].

The authors studied 1,766 renal biopsy specimens obtained from 1,350 patients with hypertension who underwent sympathectomy at the Massachusetts Memorial Hospitals between 1946 and 1955. Single specimens had been removed in 940 patients, and renal biopsy had been bilateral in 410. The earliest parenchymal alterations observed were cloudy swelling, dilatation and atrophy of some convoluted tubules, and accompanying spasm of afferent arterioles. Significant arteriosclerotic lesions characterized the specimens of more than 66% of the patients. Subsequent to spastic arteriolar contraction, intramural edema and muscular hypertrophy were thought to occur. These, in time, were followed by arteriolar elastic tissue degeneration with pooling of its ground substance and, eventually, irregular collagen deposition and hyalinization in the afferent arterioles. Scars, lymphocytic aggregates in interstitial tissue, and slight or obvious glomerular alterations commonly accompanied the more advanced grades of arteriosclerosis. Fibrinoid necrosis was observed in arterioles in all grades of arteriosclerosis. These findings suggest that renal ischemia probably precedes detectable vascular abnormalities in patients with essential hypertension. When structural alterations have developed in the arteriolar walls, secondary renal changes may serve to maintain or accelerate the hypertensive process.

RADIOLOGY

Azygos Vein Dilatation Simulating Mediastinal Tumor. W. H. Shuford and H. S. Weens. Am. J. Roentgenol. 80:225-230 (Aug.) 1958 [Springfield, Ill.].

Normally the arch of the azygos vein casts a rounded ovoid or almond-shaped density, which rests in the angle between the trachea and right main bronchus. The shadow of the azygos vein becomes more prominent when in the course of cardiac decompensation a slight or moderate dilatation of this blood vessel takes place. Very pronounced enlargement of the azygos vein is rare. The authors describe a case in which acquired dilatation of the azygos vein reached such proportions that it simulated a mediastinal tumor. The patient was a 49-year-old man, who 12 years before had experienced sudden onset of right leg pain followed by rapid development of varicose veins and swelling of the legs as well as venous distention of the lower abdomen. Several years later hypertension developed. Since 1951 he had had persistent albuminuria and elevated blood urea nitrogen level. Retrograde and intravenous pyelograms in 1953 demonstrated a hypoplastic nonfunctioning right kidney. It was thought that 12 years before he had had a thrombosis of the right femoral vein with extension into the inferior vena cava and right renal vein with resulting atrophy of the right kidney and secondary hypertension. In 1955 and again in 1956 he was hospitalized for mild congestive failure, which responded to treatment. At his last hospitalization in 1956 roentgenologic examination of the chest disclosed a round, well circumscribed mass 3 cm. in diameter in the right superior mediastinum in the anatomic region of the azygos vein. This density had not been present on a chest roentgenogram made 5 months before.

Roentgenograms of the chest 10 days after admission of the patient revealed a very pronounced decrease in the diameter of the observed density. In order to confirm the impression of marked dilatation of the azygos vein, intraosseous venography was performed. Contrast medium (15 cc. of 70% Urokon) was injected into the spinous process of the 11th thoracic vertebra, leading to extensive filling of the vertebral venous plexus and opacification of the dilated azygos arch. Roentgenograms taken in the upright position approximately 4 weeks after admission failed to demonstrate the dilated azygos vein. The roentgenologic features of the azygos vein in normal and pathological conditions are discussed, and its role as a collateral channel in superior and inferior vena cava obstruction is emphasized. A study of 6 patients in whom inferior vena cava ligation had been performed 1 to 10 years previously revealed no visible increase in the size of the azygos shadow. It appears likely that cardiac decompensation was a major factor contributing to the huge dilatation of the azygos vein in the described case.

Observations on Massive Osteolysis: A Review of the Literature and Report of a Case. P. M. Johnson and J. G. McClure. Radiology 71:28-42 (July) 1958 [Syracuse, N.Y.].

The authors collected from the literature the cases of 31 patients with "massive osteolysis," a term recently introduced to identify a rare and specific type of bone dissolution, associated with a benign, noncystic osseous angiomatosis and characterized by a progressive localized resorption of bone with resultant deformity. The study of these cases revealed that the disease which was histologically confirmed in 11 of the 32 patients possesses distinctive clinical, pathological, and roentgenologic features. Histologically benign, the disease destroys bone locally and is not confined by bony margins. After a variable period of localized activity within a skeletal region, the disease underwent spontaneous arrest in 29 patients, but it resulted in death after unremitting progression in 2 patients. There are no associated endocrine or metabolic disturbances. The mechanism of bone destruction and resorption is unknown.

In its early stages the disease cannot be distinguished roentgenologically from localized, nonsclerosing osteolysis due to other causes. The roentgenologic appearance becomes diagnostic of massive osteolysis when in the course of the disease unilateral partial or total disappearance of contiguous bones, tapering of bony remnants, and absence of a sclerosing or osteoblastic reaction are observed in a child or young adult. Confirmation of the diagnosis before biopsy may be obtained by methods which opacify the angioma, either directly or indirectly. A certain amount of therapeutic success followed irradiation therapy in a few patients, although in none did complete healing occur. While the effectiveness of irradiation therapy in massive osteolysis cannot yet be critically evaluated, this method deserves thorough therapeutic trial in future cases of this disease. It is doubtful that extirpative surgery is applicable to patients with massive osteolysis although reconstructive surgery may be valuable in selected patients.

An additional case of massive osteolysis in a 29-year-old colored woman is reported. The patient, complaining of a limp and pain in the left hip, was admitted to the Memorial Hospital of the University of North Carolina. Roentgenologic examination revealed a pathological fracture of the acetabulum. After a course of external irradiation therapy with a midline tissue dose of 1,420 r delivered to the left hemipelvis and lower lumbar spine through 2 opposing ports in 18 days, calcified callus appeared, but bony union did not occur. There was a concomitant transient rise of the alkaline phosphatase level in the serum. After a second course of irradiation therapy with a midline dose of 1,900 r delivered to the left hemipelvis in 16 days, crutch walking, with no weight-bearing on the left lower extremity, was begun. Two and one-half years after the onset of the disease the patient remained able to walk on crutches, but could not bear weight on the left lower extremity which was 1 in. shorter than the right. There had been slight further resorption of the left trochanteric tip. Osseous angiography was carried out with the aid of local analgesia. Frontal and oblique roentgenograms were obtained with a serialographic camera. There was opacification of the left ilium and spread of the contrast medium into the left gluteus medius and minimus muscle adjacent to the left femoral greater trochanter. A total dose of 80 cc. of diatrizoate (Hypaque) sodium was used. About 35 cc. was recovered by intraosseous aspiration at the end of the procedure. A course of irradiation therapy to the left trochanteric region is contemplated.

Occlusion of the Abdominal Aorta. S. Chiappa. Am. J. Roentgenol. 80:297-305 (Aug.) 1958 [Springfield, Ill.].

Since the introduction of aortography, occlusion of the abdominal aorta, which hitherto had nearly always been a postmortem finding, is being recognized in living patients and is being successfully operated on. The author is concerned chiefly with 5 of 104 patients in whom abdominal aortography was performed at the Radiologic Department, Söder Hospital, Stockholm, Sweden, and at the Institute of Radiology of the University of Pavia, Italy. Aortography was performed by direct puncture of the abdominal aorta just above the level of the renal arteries. The 5 patients whose histories are presented had complete high occlusion of the abdominal aorta, accompanied by the formation of collateral circulations, which enabled the patients to survive the otherwise fatal obstruction of the abdominal aorta. The author describes the roentgenologic aspects of the collateral pathways supplying the abdominal viscera as well as the lower extremities.

The first of the 5 patients had a collateral circulation in which the superior mesenteric artery through its right side branches, i. e., middle colic artery, right colic artery, and ileocolic artery, supplies the inferior mesenteric artery by way of the long arterial arch of Riolan, which is a pre-existing anastomosis between the ascending branch of the middle colic artery and the corresponding branch of the left colic artery, the latter being a collateral branch of the inferior mesenteric artery. In another patient findings were similar, but they were less evident, owing to the greater extension of the occlusion. The blood supply to the inferior mesenteric artery and its left colic branch was made possible through Riolan's arch, which was not completely visible on the aortogram. A Smithwick operation had been combined with the removal of a thrombus from the femoral artery, thus allowing the introduction of a catheter into the right external iliac artery. In this manner, a retrograde injection had been obtained of the common iliac artery and of the terminal aorta. One could see now some of the right lumbar branches of the aorta and the terminal middle sacral branch, with its segmental anastomosis with the lateral sacral artery of the opposite side. Through these collaterals, a filling of some of the left gluteal vessels became possible. Part of the contrast medium, flowing back along the catheter, reached the internal iliac artery whose vesical and internal pudendal branches were also opacified. Finally, there was a filling of the urogenital network and of the obturator arteries, which serve as collaterals of the deep femoral artery through their anastomoses with the circumflex femoral vessels. The same situation was observed in a third patient. In all 3 of these patients a new blood supply to the distal portion of the colon was established by the collateral pathways.

In a 4th patient the restoration of the visceral circulation was more complex. It may be inferred that blood which had been able to flow from the lumbar network of the inferior mesenteric artery could retrogress through the anastomoses between the vessels of the large and small intestine as far as the branches of the superior mesenteric artery. As regards the collateral pathways to the lower extremities, the femoral network was reached through the anastomoses between the gluteal branches, the iliac circumflex and the femoral circumflex branches. In a 5th patient a high occlusion of the aorta below the renal arteries was present, owing to a partially free thrombus, which reached the superior mesenteric artery, causing it to be only partly filled. One of its right branches was connected with the left colic artery through a long anastomotic arch, thus allowing a collateral circulation to the inferior mesenteric artery, the terminal branches of which take part in the formation of the hemorrhoidal network, which is connected on one side with the sacral and on the opposite side with the urovesical network.

Roentgen Diagnosis of Acute and Chronic Traumatic Aneurysm of the Thoracic Aorta. I. Steinberg and J. A. Evans. Am. J. Roentgenol. 80:237-247 (Aug.) 1958 [Springfield, Ill.].

Aneurysms of the thoracic aorta occur more frequently, particularly in the course of traffic accidents, than is suspected. Multiple fractures and internal injuries associated with profound shock overshadow the thoracic injuries. Rupture of the thoracic aorta due to blunt trauma occurs most frequently at the top of the aorta. This is explained by the physical forces which are concerned with deceleration acting with undue stress on the aorta, producing a tear just beyond the point of fixation by the brachiocephalic arteries and the insertion of the ligamentum arteriosum. Repeated roentgenography of the chest for many weeks following injury permits recognition of mediastinal hematomas, hemothorax, and the development of a localized bulge (aneurysm) in the region of the aortic knob. Unless chest roentgenograms are made after thoracic injury, many years may elapse before chronic traumatic aneurysms of the thoracic aorta are diagnosed. Often, a mediastinal mass found in a routine chest roentgenogram in asymptomatic patients may be the first inkling of the aneurysm. In others, chest pain, cough, hoarseness, or hemoptysis may lead to roentgenologic study of the thorax and discovery of a mediastinal mass and aneurysm.

Roentgenographic examination, especially roentgenoscopy and esophagraphy, are valuable for demonstrating a mass at the top of the aorta. There is a high incidence of calcification in the aneurysmal wall in chronic cases. Angiocardiography is invaluable for diagnosis of aneurysms and readily differentiates them from mediastinal tumors. Finally, the characteristic location of traumatic aneurysms at the top of the aorta, the absence of a positive serologic test for syphilis, and the history of trauma establish the diagnosis. Operative repair of an acute traumatic aneurysm of the thoracic aorta has not, as yet, been reported. The critical condition of the patient, often in shock and with multiple fractures and internal injuries, makes surgery hazardous and formidable. Excision of chronic traumatic aneurysms of the thoracic aorta and replacements by grafts have been successfully accomplished. However, operation should be limited to those patients who show evidence of enlargement of the aneurysm and/or develop symptoms.

Splenoportography: Some Advantages and Disadvantages. M. M. Figley. Am. J. Roentgenol. 80: 313-323 (Aug.) 1958 [Springfield, Ill.].

This report is based on the author's experience with 125 attempts at percutaneous splenoportography and a review of several large series of cases, which have been reprinted since the method was first described by Abeatici and Campi in 1951. Splenoportography is usually successfully accomplished with very simple techniques. It fails in from 10 to 16% of attempts due to failure to puncture the spleen or to inject into it properly. The present techniques, while desirably simple, need modification in order to insure a more exact prepuncture estimation of the splenic position, size, and thickness. This is particularly true if the spleen is not enlarged. In such patients the "controlled" puncture technique supplemented by test injections is probably preferable to the "blind" technique. Splenoportography is relatively free from major hazards. There is some bleeding in many cases as evidenced by the fact that explorations immediately following the procedure have disclosed 50 to 200 cc. of free blood. Two of the 125 patients were still bleeding at laparotomy 30 to 60 minutes later and another had accumulated 300-400 cc. of blood near the spleen. To date none of the author's patients had had laparotomy because of bleeding, although 1 patient with unsuspected hypersplenism and thrombocytopenia required a transfusion of 1,500 cc. of blood for control of hemorrhage. Other investigators have had about the same experience with postpuncture bleeding.

Two general types of visualization are obtained. One type shows only the splenic vein fed by 1 or more hilar tributaries and the portal vein and its branches. The author feels that such images indicate no portal obstruction or portal hypertension although this does not exclude the possibility of disseminated hepatic disease. The other type shows sustained hepatofugal flow in portal and splenic tributaries. These images are considered as suggestive of some portal (or splenic) obstruction. There is evidence that portal hemodynamics are not altered by splenic injection of contrast material. Splenoportography is most rewarding in the study of portal hypertension, especially for the differentiation of intrahepatic and extrahepatic block relative to its surgical treatment. The uncommon pitfall of total diversion of the contrast material from a patent portal vein does not invalidate this indication. Other occasionally valuable applications include the positive demonstration of portal hypertension in cases of unexplained gastrointestinal hemorrhage, evaluation of patency or portacaval shunts, and the recognition of cirrhosis. As regards the detection of hepatic and pancreatic neoplasms, the method has not been consistently successful.

ANESTHESIA

The Anaesthetist and the Emphysematous Patient. J. F. Nunn. Brit. J. Anaesth. 30:134-141 (March) 1958 [Altrincham, England].

Patients with emphysema frequently require operations, but emphysema presents such a widespread disturbance of pulmonary function that anesthesia may be complicated by a number of different factors. Associated bronchitis causes the tracheobronchial tree to be hypersensitive and anesthesia may be complicated by coughing, breath holding, or bronchospasm. Postoperative exacerbation of infection may have serious consequences. Induction by inhalational anesthesia is complicated by the delayed uptake of gases due to defective mixing. Respiration in emphysematous patients is particularly sensitive to depressant drugs and, in addition, they have a diminished ventilatory response to a raised arterial carbon dioxide tension. Furthermore, reliance of these patients on the "anoxic drive" reduces the alveolar ventilation when the inspired oxygen concentration is raised unduly. These factors may precipitate a vicious circle of carbon dioxide retention leading to narcosis. After a long period of artificial ventilation, there may be some difficulty in restoring the blood gas tensions to levels which are compatible with spontaneous respiration.

Expiratory obstruction may complicate artificial ventilation and lead to hyperinflation with both respiratory and circulatory embarrassment. Cautious use of a reduced airway pressure during expiration may be of value. Neither spontaneous respiration nor artificial ventilation is free from difficulties in patients with emphysema and many anesthetists prefer to use local or regional analgesia when such techniques are practicable. After thoracotomy there is danger of postoperative hypoventilation, particularly if much functioning lung has been removed. Artificial ventilation may be the only effective treatment. Mention is made of certain operations to improve pulmonary function in emphysematous patients, such as resection of the parasympathetic nerve supply to the tracheobronchial tree, or the removal of air cysts, particularly the valvular variety causing progressive distention. The spontaneous pneumothorax, particularly the recurrent form that can be associated with emphysema, may require chemical pleurodesis or sealing of the leak. Some patients with severe emphysema pass into carbon dioxide narcosis which may be resistant to chemical stimulation. A tracheostomy alone may be sufficient to restore adequate alveolar ventilation but occasionally it is necessary to resort to artificial ventilation.

Iatrogenic Disease and Anesthesia. J. W. Dundee. Brit. M. J. 2:1433-1438 (June 21) 1958 [London].

It has recently become apparent that many forms of routine medical treatment may affect the response to anesthesia. In 1951 Davison warned anesthetists to be wary of patients who were being treated with either pentamethonium or hexamethonium, as the hypotensive effect of the methonium compound is more marked in the anesthetized than the conscious patient. A severe fall in blood pressure occurred in 2 patients during the induction of anesthesia, and sudden death followed induction of anesthesia with thiopentone and a muscle relaxant in 1 patient. In none of the 3 cases was the anesthetist aware of the methonium therapy. Based on recent work by Payne in cats and its possible application to man, patients receiving mecamylamine are liable to the same changes in blood pressure as patients on hexamethonium regimen. Rauwolfia although not a ganglion-blocking agent, does potentiate their action, causes hypotension, and may also potentiate the action of the narcotics and produce nasal congestion and excess salivation. The action of the Veratrum alkaloids on the cardiovascular system is in the form of a reflex fall in blood pressure and a reflex fall in pulse rate known as the von Bezold effect. All of the drugs currently employed in the management of hypertension are capable of affecting the course of anesthesia.

In adrenocortical insufficiency patients react to the stress of anesthesia and surgery by hypotension out of proportion to the blood loss, respiratory depression, and delayed recovery. These catastrophes from drug-induced adrenocortical failure are entirely preventable by increasing the dosage in those patients who are receiving cortisone or corticotropin prior to operation. Long-term use of chlorpromazine which is continued up to the time of induction of anesthesia prolongs the duration of action of both narcotics and relaxants. More important than its action in potentiating narcotics and relaxants are the cardiovascular effects of chlorpromazine, which include the menthonium-like potentiating hypotensive action of thiopentone. The long-term use of sedatives and analgesics leads to tolerance to their therapeutic effects which in turn causes cross-tolerance to the drugs used in anesthesia. Caramiphen and other preparations used in the treatment of Parkinsonism are reported as capable of potentiating the action of the barbiturates. Of the 589 fatalities reported by Edwards and others in 1956 the largest single cause of death was regurgitation and vomiting (110 of 589) followed by aspiration. Mention is made of 6 deaths due to fluid aspiration among diabetics to whom glucose had been given orally preoperatively. The potential hazard of x-ray therapy in anesthesia is depicted in the case of an individual who after having been subjected to deep x-ray therapy for 5 months prior to operation for a carcinoma of the mouth exhibited extreme sensitivity to cyclopropane. Lesser and Eason reported a death from the use of pitocin during emergence from light cyclopropane anesthesia. Failure of a child to breathe following delivery may be attributed to the anesthetic, especially if thiopentone is given, without any reference to previous analgesics. In very few cases was the anesthetist aware of the use of the various drugs prior to operation, associated hypotension, or prolonged unconsciousness with any form of routine medical treatment.

PHYSIOLOGY

Effect of Atherosclerosis and Age upon the Serum Mucoprotein and Hexosamine Levels in Man. C. J. Schwartz and H. R. Gilmore. Circulation 18:191-195 (Aug.) 1958 [New York].

Serum hexosamine levels were determined by the method of West and Clarke and serum mucoprotein levels were determined according to the method of Winzler and co-workers in 24 normal male medical students, between the ages of 19 and 35 years; in 23 men between the ages of 40 and 72 years, with atherosclerosis, most of them having anginal pain of effort, and 3 with previous myocardial infarction; and in 16 normotensive men, between the ages of 37 and 71 years, without clinical or electrocardiographic evidence of myocardial ischemia, and judged to be free from atherosclerosis on clinical assessment. Single venous blood samples were collected from the median cubital vein, and the serums were obtained after centrifugation at 3,000 rotations per minute for 10 minutes. The biochemical determinations were performed without knowledge of the source of the samples. Highly significant elevations of both the serum mucoprotein and hexosamine levels were observed in the patients with atherosclerosis; these elevations were above those observed in the men with comparable age and without atherosclerosis. There was also a trend for an increase in both these fractions as the result of aging. These findings are interpreted as reflecting an increased depolymerization of connective tissue-ground-substance mucopolysaccharides. It is suggested that breakdown of connective tissue ground-substance plays a role in the pathogenesis of atherosclerosis, possibly as a precursor to fibrogenesis.

The Position of the Corticoid in the Pathogenesis of the Congestive Decompensation. T. Di Perri and R. Guideri. Riforma med. 72:689-692 (June 21) 1958 (In Italian) [Naples].

The authors studied the correlation between hyperaldosteronism and cardiovascular congestive decompensation in patients who had both disorders at the same time. They observed that rest and dehydration diet instituted in patients who had right cardiac decompensation associated with edema resulted in the tendency of hyperaldosteronism in the urine to return to normal limits. Edema subsided through increased diuresis. Patients in whom cardiac disease was associated with hyperaldosteronuria had a lower excretion of aldosterone in the urine at night when they were in reclining position than at daytime when they were in orthostatic position. It is probable that this phenomenon is related to the circulatory factors, because there was no difference in the titers of aldosterone in the urine of patients who were in reclining position during all 24 hours. Another element supports this hypothesis: There was no difference in the titers of aldosterone in the urine between the 2-day periods if the daytime orthostatic position of the patient was combined with a course of intermittent administration of oxygen. This study also brought out that high venous blood sodium level determines increased titers of aldosteronuria in patients with cardiac disease and decreased titers of aldosteronuria in normal persons.

PUBLIC HEALTH

Epidemic Shellfish Poisoning in New Brunswick, 1957. R. M. Bond and J. C. Medcof. Canad. M. A. J. 79:19-24 (July 1) 1958 [Toronto, Canada].

Two epidemics of paralytic shellfish poisoning occurred in Canada in 1957, 1 in New Brunswick in June, the other in British Columbia in October. It has been known for many years that bivalve molluscs such as clams and mussels, in various sections of both coasts, occasionally become poisonous and are sometimes poisonous enough to produce illness and even death of consumers. In June and July, 1957, soft-shell clams (Mya arenaria) and bar clams (Spisula solidissima) from a 20-mile reach of the Bay of Fundy shore in New Brunswick caused 33 poisonings, mostly among picnickers; 14 were severe, the others mild. Four patients were hospitalized but there were no deaths. Compilation of case histories and assays of poison content of shellfish (highest—17,800 mouse units per 100 Gm. of raw meat) permitted calculations of poison dosages. Some people were tolerant to massive doses and others not. The most sensitive reacted to small doses. Loosening of teeth, incipient respiratory failure, and a recurrence of all symptoms after partial recovery were observed in the most severe case. There is evidence that the poison may be absorbed through the oral mucosa. This may explain the orderly appearance of the various symptoms of poisoning. An epidemic similar in character occurred in 1945, when 26 persons were poisoned by shellfish in the Fundy region of New Brunswick and Nova Scotia.

Since 1943, Fundy shellfish stocks have been regularly checked by the Department of Fisheries and the Department of National Health and Welfare. Based on this sampling, an exacting control has been established regulating harvesting of shellfish for market. Mussel fishing has been prohibited the year round and, during the critical seasons, dangerous clam areas have been quarantined to commercial digging. Besides this, notices have been posted, warning the general public of the risk of taking shellfish. This was done as usual in 1957. Lepreau Basin, for instance, was posted on Saturday morning, June 22; but 23 persons were poisoned by clams dug there in the next 48 hours. In interviews on the following Tuesday, several persons admitted having seen and read the warning signs. Some more convincing form of public information is required. After June 23, newspaper coverage was excellent and the authors credit it with discouraging other picnickers from eating clams. Nevertheless, on June 30 and on July 17, some shore residents ate clams and were poisoned. Signs and newspaper warnings were not enough. Public education is most important.

BIOCHEMISTRY

Effects of Dietary Proteins, Methionine and Vitamins on Plasma Lipids and Atherogenesis in Cholesterol-fed Cockerels. J. Stamler, R. Pick and L. N. Katz. Circulation Res. 6:442-446 (July) 1958 [New York].

The authors suggest that dietary imbalance with excess of some nutrients, e. g., total calories, total fats, saturated fats, refined carbohydrates, and inadequacy (absolute or relative) of others such as proteins, vitamins, minerals, and essential fatty acids, may be particularly pernicious in inducing hypercholesteremia and atherosclerosis. Four series of experiments were performed utilizing a total of 180 cockerels. The reduced protein diet was associated with a lower feed intake and weight gain. Plasma lipid levels were essentially similar in the reduced protein and control groups, although a higher incidence of thoracic aorta lesions was observed in the reduced protein group in spite of the fact that atherogenesis was otherwise essentially similar in the 2 groups. The low methionine group exhibited a level of feed intake and weight gain comparable to that of the control group, however cholesteremia, cholesterol/phospholipid (C/P) ratio, incidence of thoracic and coronary lesions, and the serverity of coronary lesions were all increased. The borderline adequate methionine group was not significantly different from its matched control. Feed intake and weight gain tended to be less in the high protein-high vitamin groups (supplementation of a purified ration) compared with controls. In 2 of the 3 series hypercholesteremia was less marked in the high protein-high vitamin groups, and with the exception of 1 bird with a minimal lesion thoracic aorta atherogenesis was absent in all high protein-high vitamin chicks. Feed intake and weight gain were greater with 35% soy protein than with the same level of casein-gelatin, although hypercholesteremia and aorta and coronary atherogenesis tended to be less marked with the soy than with the casein-gelatin protein. Feed intake and weight gain were likewise slightly less in the high protein-high vitamin group (supplementation of a commercial mash) and hypercholesteremia and aorta and coronary atherogenesis were also less marked. Separate supplementation with the high vitamin alone resulted in coronary atherogenesis as marked as the control. In the group supplemented with high protein alone the incidence of coronary atherogenesis was markedly lower than in the controls and was similar to that of the high protein-high vitamin group. In all series cholesterol supplementation at the same or twofold greater levels in the purified as compared with the commercial mash group yielded less marked hypercholesteremia and atherogenesis. The findings of these experiments indicated that high protein-high vitamin supplements suppressed hypercholesteremia and atherogenesis in cholesterol-oil-fed cockerels with both purified and commercial mash diets and that inadequacy of methionine intake aggravated the hypercholesteremic and atherogenic effects of cholesterol-oil ingestion.

Effects of Dietary Protein and Carbohydrate Level on Cholesterolemia and Atherogenesis in Cockerels on a High-Fat, High-Cholesterol Mash. J. Stamler, R. Pick and L. N. Katz. Circulation Res. 6:447-451 (July) 1958 [New York].

The reduction of protein intake in the diet of cockerels resulted in markedly intensified hypercholesteremia and atherogenesis in both the aorta and the coronary vessels. Restoration of the protein intake by the addition of soy protein with continued inclusion of 45 to 20% sucrose in the mash prevented this. These findings substantiate those of the previous report where a reduction in the dietary protein level caused significant effects on the hypercholesteremia and atherogenesis in chicks on high-fat, high-cholesterol ration. The results of the present experiment indicate that the deleterious effects observed were the result of the consequent reduction in protein intake, and not the incorporation in the diet of sucrose per se.

BOOK REVIEWS

Alcoholism. By Arnold Z. Pfeffer, M.D. Medical monographs in industrial medicine 2. Editor-in-chief: Anthony J. Lanza, M.D. Consulting editor: Richard H. Orr, M.D. Cloth. $4.50. Pp. 98. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

The author of this concise and well written volume has had a wide experience in treating patients suffering from alcoholism, particularly in the setting of a special clinic maintained by and for industrial personnel. The book covers the general approach to the problem and includes definitions, etiology, diagnosis, treatment, and prognosis. Descriptions of the medical and neuropsychiatric complications are adequate, and their management is clearly described. There is a good description of the Consolidated Edison–New York University–Bellevue Medical Center Plan, the clinic in which the author works. There are some interesting observations on the analytic and psychiatric approach to this problem that should be of value to the reader. The medical treatment is well outlined, and details of treatment are given. Various industrial programs for alcoholism are mentioned, and additional facilities are listed. This book should be of special value to those who have had some experience with alcoholic patients. It offers a good reference for general physicians interested in the care and treatment of alcoholics and for physicians connected with industrial medical departments.

The Physiology and Pathology of the Cerebellum. By Robert Stone Dow, M.D., Ph.D., Associate Clinical Professor of Medicine (Neurology), University of Oregon Medical School, Portland, and Giuseppe Moruzzi, M.D., Professor and Head, Institute of Physiology, University of Pisa, Pisa, Italy. Published with aid of Dean J. B. Johnston Memorial Fund. Cloth. $12.50. Pp. 675, with 185 illustrations. University of Minnesota Press, Minneapolis 14; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England; Thomas Allen, Ltd., 266 King St., W., Toronto, Canada, 1958.

At a time when most books on the newer aspects of the medical sciences are symposiums in which each author reports on a special problem and frequently disregards its relation to the whole, the attempt of these two authors to give a survey of a large area of research is most welcome. The authors, well known for their extensive work in neuroanatomy and, particularly, neurophysiology of the cerebellum, combined their efforts in writing the section on the physiology of the cerebellum, whereas Dow is responsible for the shorter clinical part. They first review the literature on the effects of cerebellar ablation and on the stimulation of the cerebellar cortex and nuclei. These chapters are followed by one concerned with the extensive electrophysiological work of the past two decades and a section on the relations between the cerebellum and the spinal cord, the cerebral cortex, and the labyrinth. In addition, the influence of the cerebellum on the autonomic nervous system is discussed. There are also short chapters on the history of cerebellar research and on developmental physiology of the cerebellum. Although a supplementary volume on comparative anatomy of the cerebellum is in preparation, the authors do not neglect the anatomic relationships. There is a thorough discussion of the world literature on every conceivable aspect of cerebellar physiology which makes this book indispensable to the neurophysiologist. The careful and critical evaluation of the experimental findings is admirable. The book shows the great erudition of the authors. It is clearly written (although too complex for the general medical reader), is abundantly illustrated, and contains an extensive bibliography. The classic theories of cerebellar function of Luciani and Holmes are critically discussed, but no new theory is presented covering such important new findings as the exteroceptive and visceral cerebellar projections, the modification of autonomic reflexes through the cerebellum, and the complex relations existing between the cerebellum, the brain stem, and the intrafusal system innervating the muscle spindles. The authors believe that the time is not yet ripe for any attempt to formulate a new concept of cerebellar functions. The second part of the book discusses the symptoms and lesions of the cerebellar disorders. The description is succinct but well documented. Each chapter is provided with a clear summary. The whole work is an outstanding contribution to the medical literature.

Diseases of the Esophagus. By J. Terracol, Professor of Faculty of Medicine of Montpellier, France, and Richard H. Sweet, Associate Clinical Professor of Surgery, Harvard Medical School, Boston. [Based on second edition of "Les maladies de l'esophage," 1951.] Cloth. $20. Pp. 682, with 408 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1958.

To those familiar with Terracol's original comprehensive book on the esophagus, this English translation is most timely and welcome. The esophagus, long neglected by clinicians other than a few enthusiastic endoscopists, has recently become a subject of numerous monographs and textbooks. The thorough manner in which Terracol has covered the subject has, fortunately, been retained by Sweet, who has added much to the book, includ-

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

ing his own and other surgical contributions that have so changed the management of diseases of the esophagus in the past 15 years. Unfortunately, the chapters on physiology and endoscopy have not received a similar critical revision. This is most apparent in the use of obsolete illustrations that detract from the appearance of the book. Terracol's section on gastroscopy has not been included in the translated version, since the book concerns the esophagus alone. The voluminous bibliography stresses the European and, particularly, the French contributions. This book should be of interest to gastroenterologists, radiologists, endoscopists, and thoracic surgeons. It has been made much more practical through rearrangement and condensation in translation.

Fractures and Other Injuries. By members of fracture clinic of Massachusetts General Hospital and of faculty of Harvard Medical School. Edited by Edwin F. Cave, M.D. Editorial Board: Joseph S. Barr, M.D., and others. Cloth. $28. Pp. 863, with 612 illustrations, drawings by Muriel McLatchie Miller, photography by Donald Withee. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1958.

The organization of a fracture clinic and fracture service in the Massachusetts General Hospital was begun by C. L. Scudder in 1917. From 1917 until 1947 the clinic was directed by a general surgeon with one or more orthopedic associates. Edwin Cave was the chief of this clinic from 1947 to 1957. In the preparation of this volume he has been ably assisted by an editorial board, consisting of Joseph S. Barr, Bradford Cannon, Claude E. Welch, and James C. White. Each chapter in this impressive book was written by one or more of 39 distinguished contributors. In addition to a thorough and excellent presentation of the methods and techniques of dealing with fractures, this book discusses such basic problems as the organization of a fracture service, metabolic response to trauma, metabolic bone disease with consideration of the susceptibility to trauma of bones so affected, the use and abuse of x-rays in fractures, traumatic shock, and anesthesia for the injured. There are, also, chapters on cranial-cerebral injuries, injuries to the spinal cord and cauda equina, injuries of peripheral nerves, chest injuries, soft tissue repairs, the management of abdominal injuries, injuries to the genitourinary tract, and blood vessel injuries. The word "rehabilitation" is often heard, but most physicians are not adequately informed of the significance of the process and the techniques of physical medicine and rehabilitation. The chapter on this subject should be valuable to all physicians who read it. This is a remarkable book. Never before have so many specialists combined their abilities and experiences in the preparation of a single book dealing with fractures and other injuries. In an era when there is danger of mass casualties occurring in any thickly populated area, it is important that every physician, regardless of his special interest, be informed about the techniques of dealing with acute injuries to any part of the body. This book should be available in every hospital or medical school library and should be in the office library of every physician who may be called on to treat fractures or other injuries.

Social Class and Mental Illness: A Community Study. By August B. Hollingshead, Ph.D., Professor of Sociology, Graduate School, Yale University, New Haven, Conn., and Fredrick C. Redlich, M.D., Professor and Chairman, Department of Psychiatry, School of Medicine, Yale University. Cloth. $7.50. Pp. 442, with illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, England, 1958.

This volume is the first part of a five-year research project by a team of social scientists and psychiatrists who have investigated the influence of social stratification on mental illness in a community of 250,000. The research was focused on two questions: Is mental illness related to social class? Does a mentally ill patient's social level affect the treatment for his illness? To answer these questions the authors carried out a series of studies on the social structure of the community. In their report they describe the characteristics of typical families in five different social levels. They conducted similar studies of psychiatrists in private practice and in public and private hospitals. They likewise surveyed all patients in psychiatric treatment and the institutions in which they were being treated. As a result they made some startling discoveries regarding the care of mentally ill persons in New Haven, Conn., which practicing physicians and all those interested in medical research should find worth reading. This carefully conducted project raises many questions for additional studies of the medical care of the mentally sick. It is hoped that similar studies will be undertaken in other communities and that similar surveys will be made of patients in general medical and surgical hospitals in the same community in which this report was developed or in other communities of similar size.

Modern Trends in Pediatrics (Second Series). Edited by A. Holzel, M.D., D.C.H., and J. P. M. Tizard, M.A., B.M., M.R.C.P. With foreword by Wilfrid Gaisford, M.D., M.Sc., F.R.C.P. Cloth. $14. Pp. 372; 13, with 46 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1958.

The authors of this book selected a large group of specialists to discuss recent and future trends in their respective subjects. These include geneticists, virologists, physiologists, neurosurgeons, statisticians, psychiatrists, and physicists. There is some fine information in this volume to stimulate both pediatricians and general practitioners. The book, while not all inclusive, deals with the most important problems of pediatricians today. It is well written and is highly recommended to those interested in this field.

QUESTIONS AND ANSWERS

PROPHYLAXIS FOR POISON IVY

To the Editor:—*Please give information about the most recent prophylactic management against poison ivy and poison oak.*

Gerald L. Downie, M.D., Kankakee, Ill.

Answer.—Obviously, the best prophylaxis against poison ivy or poison oak dermatitis is avoidance of exposure to the plants. This is not always possible. Most exposure is accidental, seldom anticipated, and often inescapable. The use of protective creams, lotions, and ointments applied prior to exposure has proved only partially successful. Those that contain zirconium, when used before or very soon after exposure, are more effective because they inactivate urushiol, the active principle of the plant, which produces the dermatitis. Desensitization in one form or another has been employed with varied success for many years. Eating leaves of the offending plant was reported among the American Indians more than 150 years ago; even today farmers are said to chew a leaf occasionally as a prophylactic desensitizing measure. Oral administrations have always been preferred to the parenteral method. Several commercial prophylactic preparations in tablet and liquid form for oral administration have been available for a long time. Each has its proponents, and each, no doubt, has had some measure of success. For the most part, these products are alcoholic solutions of the plant's oleoresin or pulverized dried leaves or seeds. The saturated analogue of the active principle of the poison ivy plant, 3-pentadecylcatechol, has been used experimentally with good results but seems to be too toxic for general use. At the present time, the most promising product is an alum-precipitated pyridine extract. This does not appear to have toxic qualities. Until recently, desensitization with this extract had to be performed parenterally. It is now available in tablet form, and its efficacy was reported by Langs and Strauss (in a paper read before the Section on Dermatology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958).

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

GENERALIZED VACCINIA

To the Editor:—*A 23-month-old child was vaccinated for smallpox. After receiving the vaccine, he remained completely afebrile and asymptomatic for seven days, except for the appearance of a pearly gray vesicle at the site of inoculation. On the eighth day, he began to have a low-grade fever and symptoms of generalized malaise. On the ninth day, the temperature spiked to 102 F (38.9 C); 24 hours after the initial temperature elevation, the patient broke out in a fine, flat, macular, erythematous eruption, with the lesions measuring 3 by 3 mm. in diameter. These lesions first appeared on the chest and extended from the clavicles to the symphysis pubis. Within three hours they had extended to the back, beginning at the hair line and extending down to the buttocks. The vesicle at this time became desiccated and was surrounded by a 6-cm. area of erythema. Findings on physical examination were otherwise essentially negative. No medicaments were given at this time. Physical examination on the 10th day revealed the pharynx to be injected, and in view of this finding the patient was given 300,000 units of procaine penicillin. Chlorpheniramine was given under the assumption that this rash was an allergic response to the vaccine. The rash began to fade four days after the initial eruption; however, the remaining lesions began to have a purpuric appearance. The area around the vesicle also became purpuric and resembled the color of the maculopapular rash on the patient's trunk. Ten days after the first appearance of the rash, the lesions had completely subsided and the patient was afebrile and asymptomatic. His history is essentially negative, with no previous record of allergy. If this was an allergic phenomenon, would it be safe to revaccinate the child in five years, or should he be vaccinated at a shorter or longer interval than the prescribed five years? Should any precautions be taken at time of revaccination?*

Ronald G. Aucoin, M.D., New Orleans.

Answer.—The clinical picture presented by this patient appears to be compatible with generalized vaccinia. The possibility of eczema vaccinatum could be discarded on the grounds of lack of previous existence of eczematous lesions. Generalized vaccinia is a rare condition; its frequency has been estimated by Jubb, from a study of the records of the Ministry of Health in London (Report of the Committee on Vaccination, Ministry of Health, London, His Majesty's Stationery Office, 1928), to be of the order of 1 in 100,000 vaccinations. It occurs between the 9th and the 14th day as a widespread papular rash which later vesiculates. This condition is fatal on occasions and might lead to vaccinia gangrenosa—apparently due to inability of the patient to develop antibodies against the vaccinia virus—which almost invariably ends in death. The reasons for the spreading of the virus in generalized vaccinia are unknown but seem to depend on a personal idiosyncrasy of the patient (Scott, Viral Infections, in Nelson, Textbook of Pediatrics, Philadelphia, W. B. Saunders Company, 1954).

Concerning the queries, under normal circumstances it appears that this child should not be revaccinated, since there is evidence of his sensitivity to the vaccine. Weighing the risks of having a serious complication, which might be fatal, against the practically nonexistent chances of acquiring smallpox in the United States, abstention appears to be a sound procedure. An interesting problem would occur if, in the years to come, this child were to come in contact with a patient with smallpox. At that moment the situation should be reevaluated on its own merits, and either vaccination or the administration of specially prepared gamma globulin from a pool of recently vaccinated adults could be considered.

SERUM CHOLESTEROL LEVEL AND INFERTILITY

To the Editor:—*What is the significance of slight elevation (up to 300 mg.%) of the serum cholesterol level in otherwise healthy males, aged 25 to 35 years, seeking treatment for infertility? These elevations are present without any change in the protein-bound iodine levels. What can be used to decrease the cholesterol level?*

Murray Russell, M.D., Garden Grove, Calif.

Answer.—Nothing is known of a relationship between a slight elevation of the serum cholesterol level and infertility. The condition may, however, reflect a subclinical thyroid insufficiency, which should be looked for and, if present, corrected. Laboratory studies indicate that the serum cholesterol level can be reduced either by lowering the total intake of food calories or by increasing the relative proportion of unsaturated to saturated fats in the diet. Such dietary treatment, however, is scarcely indicated in the cases cited.

Answer.—Increased cholesterol level is indicative of defective fat metabolism in the liver or elsewhere or poor fat uptake by the thyroid. The protein-bound iodine test relates to iodine metabolism by the thyroid. Fat metabolism may be deranged even though protein-bound iodine values are normal. While thyroid function is vital in fertility, there is no evidence that defects in cholesterol metabolism are incompatible with fertility. It may be possible to reduce the cholesterol level by giving thyroid extract, starting with small doses, ¼ to ½ grain (15 to 30 mg.) daily, and increasing the dosage carefully as required and as tolerance permits.

TREATMENT OF SNAKE BITE

To the Editor:—*Last summer an 8-year-old girl, on vacation, was bitten by a rattlesnake. Prompt incision of the wound with a razor blade and mouth suction to remove the venom was done immediately by her father. Antisnakebite serum was administered by a tourist physician, a package of serum having been left some years previously by a tourist at the general store near by. The child was then taken to a hospital, where an additional injection of serum was given. She suffered no ill effects from the snake bite, but she did suffer severely from serum-sickness and was rehospitalized as a result. Will there be any residual immunity from the serum she has taken, in the event she should again be bitten by a rattlesnake? If not, should another injection of the antivenom be given? It appears that her reaction is to the horse serum. Are there any preparations manufactured that do not use horse serum? If it is necessary to reinject one of the standard antivenom preparations, what is the best treatment for the serum sickness if it occurs?*

Walter H. Sisson, M.D., Portsmouth, Ohio.

Answer.—The treatment of venous snake bites continues to be a controversial subject. The injection of antivenin produces only a passive immunity during which the venom is neutralized. The benefits of the antivenin are transient, since the serum is destroyed in the body within a relatively short period of time. If a person is bitten again, it is necessary to repeat antivenin therapy. However, it is important to determine if envenomation has taken place. This can best be judged by the development of local and general symptoms. A bite from a rattlesnake does not necessarily indicate that antivenin therapy should be given. There is only one antivenin produced in the United States and it is made from horse serum. It is said to be effective against rattlesnake, water moccasin, or cottonmouth bites. There is no antivenin available in this country against the coral snake. Copperhead bites are seldom serious enough to justify antivenin therapy.

The following recommendations have been gleaned from a large number of clinical reports by expert venomologists, and they represent a conservative and effective approach to the treatment of venomous snake bites.

1. Upon being bitten the victim should remain as inactive as possible. Exercise increases the circulation and facilitates distribution of the poison throughout the body.

2. A tourniquet should immediately be applied about 2 in. proximal to the bite. It should be sufficiently loose to permit a finger beneath it, and one should be able to palpate the pulse beneath. If the affected part turns cyanotic, the tourniquet is too tight and should be loosened for about 20 seconds every 15 minutes.

3. Antivenin should be administered as soon as possible if there is symptomatic evidence of envenomation. Give full dosage; do not give divided doses over a period of time. If the person has been severely intoxicated, the antivenin should be given intravenously. If envenomation is only moderate, antivenin should be given subcutaneously. Directions provided by the manufacturer of the antivenin should be carefully followed.

4. The administration of cortisone either prior to or concurrently with the antivenin is said to be useful in reducing the effects of serum sickness. Immediate control can generally be accomplished with the use of epinephrine, which should be available at the time the antivenin is administered. Snake bites are generally contamined wounds. Tetanus antitoxin and antibiotics are indicated.

Some workers claim to have obtained excellent results with cryotherapy by immersing the affected part in iced water for extended periods of time, which may vary from several hours to several days, depending upon the severity of the bite. Freezing of the tissues must be avoided. The trend is definitely away from incision and suction.

LACTIC ACID BACILLI IN COW'S MILK

To the Editor:—*What is the source of the lactic acid bacilli in cow's milk? Are they present within the udder or do they gain access in the process of milking and later handling? Is it theoretically possible to obtain sterile cow's milk by careful avoidance of contamination?*

M.D., California.

Answer.—Apparently, lactic acid bacteria are present in the milk as it comes from the cow. They do not generally gain access in the milking and later handling. Early in the history of bacteriology it was thought that milk was sterile when it came from the udder. However, there have been many studies since then showing that in aseptically drawn samples of milk there is an average of 25,000 bacteria per milliliter (Thaunton and Strynadka, Annual Report of the International Association of Dairy and Milk Inspection, 1934).

URGE TO INHALE GASOLINE FUMES

To the Editor:—*A 5-year-old boy has an uncontrollable urge to inhale gasoline fumes. If unnoticed, he will inhale these fumes until he falls unconscious on the ground, and, when brought into the house, he will sleep as long as two hours. When he awakens he is hungry and appears to be no worse for the experience. If he is detected inhaling the fumes he will run and hide. Corporal punishment has done no good. This patient is well developed in every way except for a moderate speech defect. What harm, if any, can result from inhaling gasoline fumes? Would psychiatric consultation be advised?*

A. C. Scott, M.D., Evansville, Ill.

Answer.—This child's urge to inhale gasoline fumes would seem to have the same general significance as that of the adult (or child) who subjects himself, compulsively, to intoxication with alcohol, ether, or certain other narcotic or anesthetic substances. The repetitive experience may become an addiction. Psychiatric consultation is certainly indicated if wise parental guidance or discipline fail. An episode of sublethal intoxication from a present-day gasoline, while usually without important sequelae, cannot be counted on to be harmless. Certainly, recurrent bouts of intoxication should be avoided, especially in view of the occurrence of appreciable quantities of aromatic hydrocarbons in many commercial gasolines. These compounds, which are generally more toxic than straight or branched chain hydrocarbons, derive largely from modern technological processes in the petroleum industry, and, while a number of the aromatic components of gasoline in pure form, e. g., toluene, ethylbenzene, and cumene, have little or no specific effect on the blood forming tissues, benzene (C_6H_6), which may comprise as much as 6 or 7% of the volume of the gasoline, may conceivably occur in vaporized gasoline in sufficient concentration to exert its injurious effects. The risk associated with mild gasoline intoxication in the case of this child may well be moderate, but the difference between concentrations of gasoline that are capable of inducing unconsciousness, on the one hand, and fatal narcosis, on the other, is not so great as to be evident either to the child or to other observers. This situation, therefore, is one which may have a tragic outcome.

Answer.—This consultant cannot comment on the physical effects of inhalation of gasoline fumes; it is definitely a psychiatric symptom and may be considered a perverse activity. The child obviously receives gratification, and the activity is of an impulsive and compulsive nature. The pleasure is anal-erotic. To a degree this is found in all children and adults, but for an emotional reason it has become exaggerated in this case. A full psychiatric evaluation would, no doubt, elicit other additional psychiatric symptoms.

VESICULAR AND BULLOUS DISEASE

To the Editor:—*Please suggest effective management for a case of porphyria cutanea tarda. A middle-aged woman is in her first acute episode; she has had countless large and small blisters on the exposed areas of her neck and upper extremities. A moderate dose of cortisone had the surprising effect of clearing the areas involved with small vesicles, but apparently it did not affect the development of large bullae. Therapy with all incidental medicaments which might have influenced the onset has been discontinued.*

Leonard Nelken, M.D., Clinton, Iowa.

Answer.—It would have been of immeasurable value to have had a more complete history and a statement of the methods used in arriving at this diagnosis. Have each of the vesicular and bulbous-producing diseases, such as pemphigus and dermatitis herpetiformis, been eliminated? Is there a history of taking chloroquine phosphate, sulfanilamide, or any of the oral antidiabetic preparations? Is there a history of alcohol consumption? The laboratory findings would also be of value. Clinically, is there any evidence of melanosis, hypertrichosis, anemia, abdominal nervous symptoms, and a purplish hue of facies? The patient with photosensitive and chronic disease must be protected from strong sunlight by both chemical and chemicomechanical means. Total abstinence from use of alcohol, barbiturates, and arsenic is also necessary. Such drugs as chlorpromazine hydrochloride, other phenothiazine derivatives, and promethazine hydrochloride, which are photosensitizers, must be prohibited.

ALLERGY TO HARD-SHELLED CLAMS

To the Editor:—*Whenever a patient eats hard-shelled clams (quahogs) he develops cramps within two hours after ingestion. The cramps are severe, constant, limited to the epigastrium, and can be relieved only by induced vomiting. The patient can eat other fish and shellfish, such as soft-shelled clams, lobsters, oysters, and scallops, without ill-effect. What is the ingredient present in quahogs, and not in the other types of shellfish, which gives this reaction? Ingestion of little necks (the baby quahogs), or of a single clam will produce the symptoms.*

Edward Damarjian, M.D., Providence, R. I.

Answer.—Quahogs (Venus mercenaria), soft shelled clams (Mya arenaria), and scallops (of the suborder Pectinacea) all belong to the large biological class of Lamellibranchia, of which there are 7,000 species and more than 100 families. The smallest is one millimeter in size, and the largest, Tridacna gigas, itself weighs 20 lb. and possesses a shell weighing over 500 lb. All three belong to different suborders, as does the oyster.

There are three problems involved. First, is this a form of allergy? Although skin tests are routinely negative unless other organs participate with the gastrointestinal tract in the symptoms, nevertheless, the syndrome described with or without diarrhea is so clearly defined and so often seen that no other term is applicable.

In some patients the problem, of course, is that the cause may not be the quahog alone. It is sometimes eaten raw with a spiced tomato sauce, horseradish, and other allergenic foods or spices which may be gastric irritants, although there are cases when this does not hold, as in quahog chowder (the clam chowder of commerce), but here again other ingredients may be responsible for the gastrointestinal symptoms.

The third aspect of the problem is the most puzzling and one to which there is no present answer. Sensitivity can be specific or else quite general. Examples are seen of sensitivity to one type of fowl, as chicken but not turkey or pheasant, although some patients can tolerate no avian meat. Analgous is the patient sensitive to one fur-bearing animal as compared to others sensitive clinically to all animal danders. Similarly, sensitivity may exist to one sulfonamide and not to others or to all derivatives of sulfanilic acid. This is also true of tetracyclines. It would be best for the patient to avoid quahogs, especially since he can enjoy so many other types of shellfish.

CONSTANT TWITCHING OF EYE

To the Editor:—*A woman has had a constant twitching of her right eye and the entire side of her face, including brow and cheek. She states this is relieved when she removes her glasses and retires at night but recurs when she arises in the morning. An ophthalmologist could not find any relationship between her glasses and the twitching. Therapy with tincture of gelsemium was given after other antispasmodics were tried, but as much as 24 drops has produced no drooping or relief. In March, 1958, a facial nerve was injected with procaine hydrochloride, and Solu-Zyme was given intravenously, but to no avail. Is there any other medication that might relieve this twitching?*

Kenneth A. Ohme, M.D., Mitchell, Neb.

Answer.—The data supplied by the questioner are inadequate to make a definitive diagnosis as to the cause of this patient's facial twitching. So-called essential facial spasm may be responsible for her symptoms. In this condition irritative processes, as a result of old inflammation in the facial nerve as it passes through the facial canal, may be responsible and may be relieved partially and temporarily by operative decompression of the nerve. Recurrences after such operations are common (Williams and others, Ann. *Otol. Rhin. & Laryng.* 61:850, 1952). On the other hand, it is notorious that such symptoms may occur in the form of a hysterical tic, and careful and prolonged clinical observation of the patient may be necessary to distinguish between these two conditions. If the disturbance is indeed hysterical, psychotherapy is, of course, the treatment of choice, but such tics are uniformly resistant to psychotherapy. Drug therapy in that case is apt to be of no avail, but one might try reserpine in moderate doses or chlorpromazine, 50 mg. three times a day.

MYXEDEMA

To the Editor:—*In 1950, a 45-year-old man had exophthalmos, loss of weight, tachycardia, and palpitations. The diagnosis then was hyperthyroidism of diencephalohypophysial origin with edematous exophthalmos. In 1951, radiotherapy (4,000 r) of the hypophysial regions was done. In 1952, a fixation test with radioactive iodine (I^{131}) showed hyperfixation of I^{131} and hyperfunction of the thyroid up to maximal limits. In 1953, a single oral dose of I^{131} was given. Since 1955, the patient has complained of fatigue, headache, and vertigo. His basal metabolic rate has been —38%, and the cholesterol level has been 240 mg. per 100 cc. Thyroid treatment could not be given, since even a small dose produces palpitations and makes the condition worse. What therapeutic measures and further investigations should be done?*

Emile Quiring, M.D., Luxembourg, Belgium.

Answer.—It would seem from the data presented that the patient almost surely has myxedema. Confirmation of the diagnosis should be made by careful determination of the physical signs, by further studies of the basal metabolic rate, and by determination of the protein-bound iodine level of the blood. If the diagnosis of myxedema is confirmed, desiccated thyroid or thyroxin should be administered in a dose adequate to raise and hold the basal metabolic rate between —10% and zero. Untoward symptoms occurring during the early stages of treatment often subside after treatment has been carried out for a few weeks. Small doses of desiccated thyroid or thyroxin gradually increased may minimize untoward symptoms, and, in some instances of incomplete myxedema after treatment for toxic diffuse goiter (Graves' disease), the concomitant administration of iodine and desiccated thyroid appears to have been of help in this regard.

HYPERTRICHOSIS AND ACNE

To the Editor:—*Three different girls, in their late teens, have had excessive hairiness and acne of the face and trunk. These girls have had androgen excretion rates ranging from the upper limits of normal to 15 and 20 mg. per 24 hours. The 11-oxysteroids values have been normal (at the median of the upper and lower limits of normal). These girls have menstruated normally and regularly. Hypertrophied clitoris is not present, and libido has not been excessive. Histories and results of physical examinations were normal. Findings on all the usual laboratory examinations, such as blood cell count, blood sugar determination, glucose tolerance test, and blood cholesterol determination, have been negative. However, blood uric acid levels have been, interestingly enough, at the upper limits of normal, namely 5.5-6 mg. %. One patient said that her mother and sister have had excessive hairiness. Particular attention has been paid to other evidence of endocrine dysfunction; however, nothing of significance has been noted. What effective therapy could be given?* *M.D., Washington.*

Answer.—There is no reasonably effective treatment for the hypertrichosis in such patients. Some instances are familial, others are not. Facial hair can be removed by electrolysis. However, the acne should be brought under control first; otherwise, the electrolysis "wounds" might become secondarily infected. The acne can be treated best by a dermatologist with x-ray therapy, local remedies, and dietary control. Treatment with estrogens has been disappointing in the experience of this consultant in patients with acne with or without hypertrichosis. As far as is known, the blood uric acid findings are not significant in the etiology or treatment of the hypertrichosis and/or the acne.

REACTION TO DIETHYLSTILBESTROL

To the Editor:—*A patient has proved carcinoma, grade 2, of the prostate. He receives a pill containing 100 mg. of diethylstilbestrol, 667 mg. of ascorbic acid, and 10 mg. of riboflavin three times a day. Could this treatment produce night sweats and dizziness?*

A. L. Henrichsen, M.D., Van Nuys, Calif.

Answer.—A dosage of 100 mg. of diethylstilbestrol is unnecessarily large for therapy for carcinoma of the prostate. It is open to question whether large attention to a possibility of increasing social security taxes to finance purchase of health insurance at the time of retirement. The study is under way.

THREE NEW MAJOR APPOINTMENTS IN HEALTH FIELDS

Three major health appointments in the federal government have been made in recent days.

Major Gen. Oliver K. Niess takes over as surgeon general of the Air Force Dec. 1, succeeding Major Gen. Dan C. Ogle, who is retiring after nearly 30 years of service. General Niess is now command surgeon of the Pacific Air Forces in Hawaii; in this post he was instrumental in establishing medical care for U. S. nationals throughout Southeast Asia. Under General Ogle, the Air Force set up the Aeromedical Research Center at Brooks Air Force Base and constructed 170 new medical facilities worldwide.

Dr. W. Palmer Dearing has been named director of health services for the newly merged Office of Civil and Defense Mobilization. Prior to the reorganization he had been assistant director for health in the Office of Defense Mobilization, which Congress last session merged with the Federal Civil Defense Administration. Dr. Dearing's office will be the focal point for health activities remaining in the new agency; many will be shifted to Public Health Service.

Dr. H. Van Zile Hyde has been named assistant to the surgeon general of the Public Health Service for international health and will serve as chief advisor to the surgeon general on all international health affairs. His duties will include liaison with the State Department and other agencies concerned with international health, and he will continue to represent the U. S. on the executive board of the World Health Organization. Dr. Hyde has been chief of the division of international health for the last five years.

That post has been filled by Dr. Horace DeLien, who has directed the health program of the International Cooperation Administration in the Philippines for seven years.

NEW URANIUM ISOTOPE STANDARDS DRAWN

National Bureau of Standards in cooperation with Atomic Energy Commission has prepared the first in a series of uranium isotopic standards for use by educational and research institutions and industry in the U. S. and abroad. Ten standard uranium isotopic samples became available Oct. 1 from the bureau, and 5 more uranium standards are in preparation to make a series of 15.

"Standards for other atomic energy materials such as plutonium and thorium will be made available under a continuing program designed to provide materials of known certified composition which will be universally acceptable as analytical standards," a joint statement declared.

In a separate announcement, AEC told for issuance of a regulation effective Nov. 3 is designed to assure suitable precautions in shipment of special nuclear material. AEC there would be no bomb-like explosion in accidents; there could be cases of spread of ra active material.

CIGARETTE CLAIMS BARRED BY FTC

A five-year-old case between the Federal T Commission and Liggett & Myers Tobacco Co. advertising claims of Chesterfield cigarettes been concluded. FTC's final order forbids that the cigarettes are "milder," that they have adverse effect upon the nose, throat, or acces organs," and that they are "soothing and relax

A FTC hearing examiner a year ago had rec mended that the claims of milder, soothing relaxing be allowed. The commission, on the hand, cited unanimous testimony of experts various fields of medicine that cigarette smoke "an irritant capable of affecting adversely to extent" nose, throat, or accessory organs.

On the claim of soothing and relaxing, FTC this effect depended on the smoker. For habi smokers, it said, a cigarette may afford "some te porary palliation of tension" but that this was so for all smokers of cigarettes. The said the term milder was meant to convey in its physiological connection rather than in nection with such sensory feelings as taste or sme

PAN AMERICAN HEALTH PLANS FOR 19

Latin American public health programs for 19 will total 10,600,000 dollars plus any additio donations to the malaria eradication fund. Th budget was approved at the recent Pan Americ Sanitary Conference held in Puerto Rico. D were announced by the Pan American Sanita Bureau in Washington.

The conference actually adopted a budget of 3,600,000 dollars. Added to this will be about 7 mil lion dollars of World Health Organization an United Nations Technical Assistance funds. In a there are about 125 health programs underway or planned. Other conference developments:

The policy-making Pan American Sanitary Or ganization voted to change its name to Pan Ame can Health Organization on the theory that it "mor accurately describes the character of the organiza tion and its functions in the broad field of publ health." The name of the operating agency, Pa American Sanitary Bureau, remains unchanged.

An encouraging report on progress made in the last four years in malaria eradication was presente by Dr. Carlos A. Alvarado, PASB's malaria erad cation chief. As of July 31, all but two countries programs are underway. Eradication had bee achieved in the U. S., Chile, Puerto Rico, and the West Indian islands of Barbados and Martinique

ADMINISTRATION SHOWS NEW INTEREST IN AID TO MEDICAL SCHOOLS

The administration is making new moves in the field of aid to medical schools. Secretary Flemming of the Department of Health, Education, and Welfare has approved the formation of an advisory committee to the Public Health Service on medical education. National leaders in medicine, education, and public affairs are being invited to serve. PHS Surgeon General Leroy Burney explains it this way:

"I do not anticipate just 'another study.' Instead I would expect the group to appraise the existing data, plans, and proposals concerned with our medical schools and the nation's needs for physicians; to sift out the areas of agreement and the areas that require further study; and to recommend the action which all groups must take to achieve reasonable and acceptable goals in the next decade."

Dr. Burney said he would like especially to have the advice of such a group as to the proper role of the PHS and the next steps the agency should take. He disclosed plans for the committee in the 13th Martin Memorial Lecture to the American College of Surgeons.

Claiming a financial crisis for medical schools goes back to the end of World War II, Dr. Burney declared: "The central imperative of these observations is that the nation must plan and act as a nation in the development of health manpower. In the complex society of today, in a period of world crisis, health and educational services can be no more be left to chance or exclusively to local initiative than can the development of heavy industry, consumer goods, transportation, public utilities, and national defense."

Dr. Burney drew heavily on the Bayne-Jones report submitted by a group of consultants to HEW last summer. In it, the consultants call for a doubling of government and private spending in medical research by 1970 and the construction of 14 to 20 new medical schools and 24 new dental schools, together with expansion of existing facilities.

"I do not predict that the goals established by the consultants will be fully achieved in the time specified, but I do see an urgent need for the same kind of bold and imaginative planning for medical education. If only a portion of the medical research goal is achieved in the next decade, the needs for health manpower will increase," Dr. Burney said. He argued that the present and predicted output of American medical schools cannot supply physicians to keep pace with the big expected population growth. Schools are producing about 7,000 graduates a year, and about 750 foreign-trained doctors are being licensed to practice in the U. S. each year.

"At predicted rates of production, therefore, we will have approximately 273,000 physicians in 1970. This number represents an increase of only 19% in physician supply over the present figure, as contrasted with predicted population increases of between 26 and 34%. Obviously, the present physician-population ratio will have dropped—and that in a period of predictable increase in demand for medical services," he added.

AFL-CIO PAMPHLET LISTS FORAND BILL AS OBJECTIVE FOR NEXT SESSION

"Labor Looks at the 85th Congress," a pamphlet just issued by the AFL-CIO, lists the Forand Bill for hospitalization under social security as among the foremost objectives in the session opening next January.

Complete overhaul of the Taft-Hartley Act "to restore both justice and equity to both labor and management" is the first of the 17 objectives listed. Points two and three are for "positive steps to safeguard union from racketeers and improper activities in both labor and management" and extension of the fair labor standards act and an increase in the minimum wage to $1.25 per hour.

Then the pamphlet plugs for the Forand Bill in these words:

"Through the social security system, provision for hospital, nursing home and surgical care for those receiving benefits."

The booklet was prepared by the AFL-CIO legislative department, under Andrew J. Biemiller.

Last session the Forand Bill was among social security changes on which hearings were held by the House Ways and Means Committee. The bill was not reported out, but the committee instructed the Department of Health, Education, and Welfare to make a comprehensive study of the problems financing medical care for the aged, with parti doses of this drug are more effective than limited doses, and the usual amount prescribed is 5 mg. three times a day. A patient's reaction to diethylstilbestrol is variable. While in most cases there is little or no reaction, it may cause such symptoms as anorexia, nausea, dizziness, and even night sweats. Whether or not diethylstilbestrol is causing the symptoms described could be proved by withholding the drug for a week or two. It would be of interest to have roentgenograms made of the patient's spine and pelvic bones to see whether metastasis is present.

EXAMINATIONS FOR SCHOOL CHILDREN

To the Editor:—*Concerning the Question and Answer on examinations for school children, which appeared in* The Journal *for Aug. 2, 1958, page 1802, I would like to mention that in about 13,000 school children tested with intermediate strength tuberculin, a reactor rate of 1.7% occurred. The consultant did not specify the use of the patch test, but as long as one is going to go to the trouble of testing one might as well do a good job of it and use intermediate strength tuberculin.*

Garold L. Faber, M.D.
315 Wall St.
Chico, Calif.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*Assuming that the 13,000 tuberculin tests were applied to children of grade school age, from 6 to 14 years, a reactor rate of 1.7% is smaller than has usually been reported in cities. It compares more favorably with testing in rural communities where there has been a good sanatorium system, control of tuberculosis among cattle, and an educational program in effect for several decades. In some such areas, testing now reveals no reactors among grade school children. Even with this low percentage of reactors, over 200 were found who have been in contact with persons with contagious disease and who themselves have lesions containing living tubercle bacilli. Each of these children has a potential for clinical tuberculosis at some subsequent time. Therefore, the effort in testing has paid good dividends and will continue to do so if an attempt is made to find the adult associates who infected the children and also if the children are examined periodically to detect clinical lesions which may evolve while they are small, noncontagious, and easily treated. The percutaneous method of administration of tuberculin, now known as the patch test, has been in use since 1908. The comparative study of Lovett* (Am. J. Dis. Child. 37:918, 1929) *showed that it is equal to or better than the epidermal method of Pirquet. The percutaneous method became popular after Vollmer and Goldberger developed a technique for its easy and fast administration; they named it the patch test. Since then, numerous comparative studies have been made which have resulted in a general belief that the patch test is equal to the usual first dose of old tuberculin or the purified protein derivative of tuberculin. Recent converters to tuberculin usually present a high degree of allergy, and, therefore, it is detected by these first test doses. This applies to both children and adults. However, when infections are of long standing and there has been no reinfection to maintain allergy at a high degree, it may wane to such a low level that it is missed by the usual first dose and the patch test. A preponderance of physicians administering the tuberculin test prefer the intracutaneous method. However, there are circumstances and situations under which it is more feasible to administer the patch test. This seems far better than to omit the tuberculin test. A number of workers have advocated doses of tuberculin intermediate between the usual first and second, such as 0.1 cc. of a dilution of 1:500 of old tuberculin. A large study initiated and promoted by Dr. C. E. Palmer and co-workers of the U. S. Public Health Service on an intermediate dose of purified protein derivative of tuberculin, consisting of 0.0001 mg. expressed as 5 international tuberculin units (TU), should produce information as to whether this is a dose that can be recommended as standard for tuberculin testing everywhere.*

FIRE HAZARDS OF VAPORIZED ALCOHOL

To the Editor:—*A Question and Answer on fire hazards of vaporized alcohol appeared in the Aug. 23, 1958, issue of* The Journal, *page 2154. The statement that no explosions are known to have occurred due to ignition of the alcohol-oxygen vapor prompts me to call attention to another explosion hazard. Several years ago I treated a patient with pulmonary edema by bubbling oxygen through rubbing alcohol (70% ethyl alcohol), administering this by tent. A rather violent explosion occurred, showering glass around the room, the hall, and into a patient's room across the hall. No one was injured. The reason for it apparently was that the rubbing alcohol contained material which solidified in the outlet of the hydrating bottle, and, when this had been blocked, the pressure in the glass bottle increased to approach that in the oxygen tank.*

ECTOPIC PREGNANCY—ANALYSIS OF THREE HUNDRED TWENTY-TWO CONSECUTIVE CASES, 1935-1954

George D. Malkasian Jr., M.D., James S. Hunter Jr., M.D.
and
William H. ReMine, M.D., Rochester, Minn.

Factors determining the incidence and course of ectopic pregnancy were studied by comparing 161 cases encountered during the 10-year period 1935-1944 with 161 encountered during the period 1945-1954. The initial complaint was abdominal pain in 38.5% and vaginal bleeding in 36.4% of the entire group; in 24% the initial complaint was simultaneous abdominal pain and vaginal bleeding. False-positive and false-negative diagnoses were frequent. Negative results from pregnancy tests were of no value in eliminating the possibility of ectopic pregnancy, and positive results did little to confirm it. Dilatation and curettage, had this procedure been performed for diagnostic purposes in all patients suspected of ectopic pregnancy, would have interrupted 18 intrauterine pregnancies that later reached term. Comparing the experience of the first with the second 10-year period showed that during the latter the surgery was in general more conservative, that blood transfusions were used more liberally, and that more women had subsequent pregnancies. No maternal deaths occurred in the last 12 years of the study.

IN THIS day of adequate blood transfusions, antibiotics, and good preoperative and postoperative care, ectopic pregnancy continues to be a cause of maternal mortality in the United States. In a recent study of maternal mortality in Minnesota, it was accounted responsible in 2.2% of the obstetrically caused maternal deaths.[1] In view of this fact, continual review of experience with ectopic pregnancy is warranted.

For this reason we have studied the experience with ectopic pregnancies at the Mayo Clinic for the 20-year period 1935 through 1954. The information presented has been obtained from study of the case records of patients given the diagnosis of ectopic pregnancy, made on clinical or pathological grounds or on both. The data have been compiled in two groups representing 10-year periods, the first 1935 through 1944 and the second 1945 through 1954. This was done so that we might (1) survey the pattern of the ectopic pregnancies in the two periods and (2) evaluate our therapeutic measures before and after antibiotics and blood transfusions became readily available.

The first 10-year period included 161 pathologically proved ectopic pregnancies, and the second 10-year period likewise included 161 pathologically proved cases. Sixteen women had two ectopic pregnancies treated at the clinic during the period of this study; therefore the total of 322 pathologically proved ectopic pregnancies occurred in 306 women.

From the Section of Obstetrics and Gynecology (Drs. Malkasian and Hunter), and the Section of Surgery (Dr. ReMine), Mayo Clinic and Mayo Foundation. The Mayo Foundation is a part of the Graduate School of the University of Minnesota. Dr. Malkasian is a Fellow in Obstetrics and Gynecology, Mayo Foundation.

Read before the Section on Obstetrics and Gynecology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

The incidence of ectopic pregnancy per total number of deliveries at the Charity Hospital in New Orleans[2] has been stated as 0.6 to 0.9%. During the first 10-year period of our study there was a total of 6,373 deliveries and 161 ectopic pregnancies for an incidence of 2.5%. In the second 10-year period there was a total of 14,224 deliveries and 161 ectopic pregnancies for an incidence of 1.1%. The high incidence of ectopic pregnancy may be accounted for by the large number of referred cases.

TABLE 1.—*Age of Patients with Ectopic Pregnancy*

	1935-1944		1945-1954	
Age, Yr.	No.	%	No.	%
20 or less	4	2	3	2
21-30	82	51	75	47
31-40	67	42	78	48
41 or more	8	5	5	3
Total	161	100	161	100
Average age	30.7		30.6	

The ages of the patients in the earlier group ranged from 17 through 47 years and in the later group from 17 through 42 years. The distribution of ages in the two groups of patients is shown in table 1. The average ages for the two groups are practically identical.

The parity of the patients at the time of the ectopic pregnancies is shown in table 2. In both groups the largest percentage were nulliparous women; they and primiparas were a majority in each group. The averages of parity in the two groups are practically the same.

Of the 161 patients in the earlier group, 39 stated that they had had one or more abortions. Of these, 28 reported one abortion, 9 reported two, and 2 reported five abortions each. Of the 161 patients in the second period, 45 stated that they had had one or more abortions. Of these patients, 30 had aborted once, 11 had aborted twice, 3 had aborted three times, and 1 had aborted four times. Thus the percentage of patients who had abortions in the two groups was, respectively, 24.2 and 27.9. Randall and co-workers[3] reported a 5.5% incidence of abortion in the group they studied but stated that other authors have expressed the opinion that 20% of all pregnancies terminate before the child is viable.

Diagnostic Factors and Decisions

Initial Complaints.—In our series, as in others, the most frequent initial complaint was abdominal pain. In the entire group 38.5% had abdominal pain alone as the initial complaint, 36.4% complained of vaginal bleeding initially, and 24.2% listed simultaneous vaginal bleeding and abdominal pain as their initial complaint. Only 0.6% (two patients) had no symptoms—that is, the ectopic pregnancy was found incidentally at the time of operation for some other condition—and one patient went into shock without any symptom prior to that.

A symptom frequently mentioned as present in ectopic pregnancy, although not initially, is shoulder pain. In our series it was present among 15.2% of the patients by the time of operation.

Diagnostic Procedures.—For this discussion, diagnostic procedures may be divided into two types: laboratory and surgical. Laboratory procedures performed routinely were urinalysis and studies of blood components (hemoglobin level, leukocyte count, differential leukocyte count, and blood group). Occasionally sedimentation rates were checked and pregnancy tests were done. In the period of awareness of the Rh factor, Rh-positive blood was not given to any of these patients before a test for presence of the factor.

We would like to emphasize at this point the necessity of testing for the Rh factor in such patients before any blood is given. It cannot be stressed too often because we still are seeing Rh-negative patients who have received Rh-positive blood without previous test for this factor. Those who have become sensitized thus have had their obstetric future jeopardized.

Twenty-four tests for pregnancy were made in the earlier group, with positive results in 70.8%, and 29 tests in the later group, with positive results in 41.4%. In all the cases in which results from the pregnancy tests were positive, the ectopic pregnancy had been suspected clinically before the test was made. We believe it can be said fairly that a negative result from a pregnancy test is of no value in ruling out an ectopic pregnancy and, furthermore, that a positive result from a pregnancy test does little to confirm the diagnosis. The latter is true because the positive test merely confirms the presence of living chorionic villi able to produce chorionic gonadotropin which has entered the maternal blood stream. The test is of no aid in differentiating an ectopic from an early intrauterine pregnancy.

TABLE 2.—*Parity at Time of Ectopic Pregnancy*

	1935-1944		1945-1954	
Para	No.	%	No.	%
0	64	39.8	57	35.4
1	46	28.6	45	27.9
2	24	14.9	28	17.4
3	13	8.1	15	9.3
4	2	1.2	5	3.1
5	1	0.6	3	1.9
6	2	1.2	3	1.9
7	3	1.9	1	0.6
10	...	...	1	0.6
Not stated	6	3.7	3	1.9
Total	161	100.0	161	100.0
Average parity	1.14		1.36	

In the first group 26 patients and in the second group 33 patients had hemoglobin levels of less than 10 Gm. per 100 ml. of blood. Of each group, 19% were admitted in shock; and all of these who had had hemoglobin tests made before transfusions fell into the group with levels less than 10 Gm.

Other diagnostic aids used—dilatation and curettage, peritoneoscopy, and colpotomy—were of a surgical nature. Opinions expressed in the literature varied concerning the value of dilatation and curettage. Beacham and associates [2] did not recommend endometrial biopsy and dilatation and curettage in the diagnosis of ectopic pregnancy, whereas Campbell [4] said that dilatation and curettage often is of aid in establishing the correct diagnosis. It must be admitted that if decidual reaction is seen in the endometrium at the time of preliminary dilatation and curettage, the procedure is of use in confirming the diagnosis. Findings from the preliminary dilatation and currettage employed in our series are indicated in table 3. The diagnosis of ectopic pregnancy had been made in all these cases before the dilatation and curettage was performed. In the earlier group, 3 (13.6%) of the 22 instances of endometrial curettage produced evidence of decidual reaction. In the later group, 7 (22.6%) of 31 instances of dilatation and curettage disclosed decidual reaction in the endometrium. This gives an over-all figure of 10 of 53 cases for an incidence of 18.9%. It indicates that dilatation and curettage gives diagnostic help in one of five cases.

TABLE 3.—*Findings at Preliminary Dilatation and Curettage*

	1935-1944	1945-1954
Decidual reaction	3	7
Early proliferative phase	1	9
Late proliferative phase	3	
Early secretory phase	8	3
Late secretory phase	1	5
Atrophic endometrium	1	
Hypertrophic endometrium	3	
Endometritis	1	
Not stated	1	7
Total	22	31

As can be seen from table 3, the two other common findings were early secretory phase and early proliferative phase of the endometrium, but the products of curettage ran the gamut of possibilities. In favor of the group who do not recommend dilatation and curettage were two cases (0.6% of the total series) in which simultaneous intrauterine and extrauterine pregnancies occurred. If dilatation and curettage had been employed, the intrauterine pregnancies would have been terminated; but, as it was, both of the patients were later delivered of normal full-term infants. Operations for the ectopic pregnancy had been performed at 8 weeks in one case and 12 weeks in the other without disturbance of the intrauterine fetuses.

In the earlier group, peritoneoscopy was performed as a diagnostic procedure in five cases, but, due to the difficulties involved, the procedure was abandoned. Posterior colpotomy then was adopted as a diagnostic aid, and at the same time it provided a means of approach to definitive treatment in a few patients. It was used as a primary approach for total salpingectomy in one patient in the early group and in nine in the later group; for partial salpingectomy in four in the later group; for bilateral salpingectomy in one in the early group; and as a diagnostic aid before laparotomy in one patient in the early and five in the later group. In each group, among the cases in which posterior colpotomy was employed, it was possible to accomplish the definitive procedure from that approach in two-thirds of the instances.

TABLE 4.—*Clinical Diagnosis of Ectopic Pregnancy*

Clinical Diagnosis	1935-1944	1945-1954
Ectopic pregnancy		
Proved to be such	123	122
Proved not to be such	69	32
Subtotal	192	154
Other diagnoses proved to be ectopic pregnancies	38	39
Total	230	193

Incidence of Diagnosis.—The summary of clinical diagnoses as compared with pathological diagnoses is shown in table 4. In the first decade the diagnosis was correct in a total of 123 of 230 cases, and in the second decade it was correct in 122 of 193 cases. Diagnostic accuracies up to 94% have been reported in the literature.[5] The high index of suspicion necessary to diagnose early ectopic pregnancy, with its often vague clinical picture, has contributed to the false-positive diagnoses shown. The 53% decrease in false-positive diagnosis in the later group has been brought about in part by the clinicians' willingness to observe patients for a longer period now that blood is readily available should it be needed.

The disposition of cases with final diagnoses other than the clinically suspected ectopic pregnancies is shown in table 5. In the earlier group nine patients were observed medically and in the later group six. The five full-term pregnancies, which in their early stages gave typical pictures of ectopic pregnancy, emphasize the importance of careful medical observation of patients who are suspected of having ectopic pregnancy and are in good condition. Surgical procedures were performed in 60 of the 69 cases difficult to diagnose in the first decade, and in 26 of the 32 such cases in the second.

TABLE 5.—*Disposition of Cases with Final Diagnoses Other Than Clinically Suspected Ectopic Pregnancy*

	1935-1944	1945-1954
Medical observation		
Spontaneous abortion later	6	4
Normal intrauterine pregnancy, delivery later	3	2
Surgical procedures		
Laparotomy	59	23
Colpotomy	1	3
Total	69	32

The pathological diagnoses in the 86 cases in which surgical treatment was used are shown in table 6. The main point of interest is that in the earlier and later groups 43.3% and 42.3%, respectively, had pathological conditions in the tubes. The intrauterine pregnancies shown in table 6 are additional to the 15 mentioned in the paragraph above as having been observed medically. The number of explorations with negative findings was small.

After this brief survey of the cases clinically suspected of being ectopic pregnancy but pathologically proved to represent other conditions, by a reversal of viewpoint table 7 shows the 322 cases pathologically proved to be ectopic pregnancies with their previous clinical diagnoses. In the two decades, 76.4 and 75.8% of the ultimately proved cases had been suspected clinically. In each of the two groups, the second commonest diagnosis was pelvic tumor, and in each of these cases it was an adnexal mass that was described by the clinician.

Treatment

The treatment of ectopic pregnancies, it is universally agreed, is to prevent or stop hemorrhage. This means surgical intervention once the diagnosis has been made. A period of close observation must be urged, however, if the diagnosis is uncertain and the patient's condition is good.

Transfusions.—Interestingly, in light of the primary aim of preventing or arresting hemorrhage, 26 patients of each group were in shock when admitted. All of these patients were treated preoperatively with blood or plasma expanders or both. Besides this use in treatment of shock, transfusions were given as supportive measures. In the first 10-year period 43 patients (26.7% of the group) received some sort of treatment aimed at increasing the volume of circulating blood. They received from 1 to 4 units, the average being 1.47 units. In the second 10-year period 62 patients (38.5% of the group) received transfusions. The amounts ranged from 1 to 8 units, the average being 2.3 units for each patient so treated.

Surgical Measures.—The operations performed in the 322 cases of ectopic pregnancy are represented in table 8. It can be seen that 78.2% of the earlier group and 86.9% of the later group had conservative operations which did not interfere with reproductive abilities. Incision of the tubes as described by Tompkins [6] and salpingotomy as described by Stromme [7] were not employed among these. The lower half of the table shows the operations that left the patients unable to reproduce—21.8% of the earlier group and 13.1% of the later group. A brief survey is warranted of the case material concerning these patients and the reasons for the operations leading to their sterilization.

Conditions of Bilateral Salpingectomy.—In the earlier group 23 patients underwent bilateral salpingectomy. Their average age was 32 years. Among the 23, 9 patients at an average age of 33 years had no living children at the time of their operations. In the tube not involved in the ectopic pregnancy, however, 14 of the 23 patients had severe inflammatory disease, 4 had hematosalpinx, 2 had obstructing adhesions, and 1 had adenomyosis. In two cases no reason was listed for the removal of the second tube.

In the later group nine patients at an average age of 33 years underwent bilateral salpingectomy. One patient had no children at the time of operation. She was 28 years old and had had three previous prolonged hospitalizations for pelvic inflammatory disease. Of the nine patients just mentioned, six had inflammatory disease of the second tube, one had hematosalpinx, and one had obstructing adhesions of the second tube. The second tube was removed from one patient because it was adherent to an ovarian dermoid.

Intrauterine death	...	1
Not stated	2	...
Total	161	161

Conditions of Hysterectomy.—In the earlier group the average age of the 12 patients who were treated by some form of hysterectomy was 31 years. Four patients with an average age of 34 years had no living children at the time of operation. In two, hysterectomy was performed because the ectopic pregnancy necessitated the loss of the second tube, the first having been removed previously. Three patients had multiple fibroids with menometrorrhagia. Two patients had chronic infection of the second tube. Hysterectomy was employed for the following reasons in one case each: extensive endometriosis involving both tubes, bilateral hydrosalpinx, massive pelvic abscess, obstruction of both tubes by adhesions from old peritonitis, and a large interstitial pregnancy in a 42-year-old patient, gravida 9, para 7.

In the later group the average age of the 12 patients having hysterectomy was 34 years. Five of them had no living children at the time, and their average age also was 34 years. For five patients this ectopic pregnancy necessitated the loss of the second tube, the first having been lost by three because of previous ectopic pregnancies and by two for unknown previous tubal disease. Three patients had extensive endometriosis and three had menometrorrhagia of such a degree that hysterectomy was thought warranted in all. One patient underwent total hysterectomy for epidermoid (squamous cell) carcinoma in situ of the cervix, and the ectopic pregnancy was an incidental finding at operation.

Associated Measures and Findings

Operations.—The most commonly associated surgical procedure was appendectomy. Of the patients who had their appendixes at the time of operation for ectopic pregnancy, 44.1% of the earlier group and 38.7% of the later group underwent appendectomy then. In light of the frequently heard statement that the appendix should not be removed electively when there is free blood in the peritoneal cavity, it is interesting to note that in 47.1% and 68.8% of the cases in which appendectomy was performed in our earlier and later groups a moderate or greater amount of blood was present in the abdomen and that morbidity in these patients was not increased. Abdominal myomectomy was performed in a few of the nulliparous women desirous of having children. None of these has become pregnant subsequently.

TABLE 9.—*Sites of Ectopic Pregnancy*

Inner third (isthmic)	6	12
Interstitial and cornual	3	8
Unstated	110	77
Ovary	1	1
Abdomen	1	...
Total	161	161

Site.—The pregnancy was on the right side in 73 cases (45.6%) of the earlier group and in 99 cases of the later group (61.5%). No correlation appeared between previous appendectomy or other previous abdominal operations and the side involved.

The site of implantation of the ectopic pregnancy in cases in which it could be determined at operation is shown in table 9. The commonest site in both earlier and later groups was the ampulla. Of the patients for whom the site was not stated, 25.4% of the earlier group and 42.7% of the later group had tubes that were described as being enlarged through their entire or nearly entire length, or tubes so far destroyed that it was impossible to determine the original site of implantation of the pregnancy. In the earlier group, 79 patients (49.1%) suffered rupture of tissue in their ectopic pregnancy, and in the later group 95 patients (59.0%) were thus affected.

One true ovarian pregnancy was found in each series, and one primary abdominal pregnancy in the early group. There were three secondary abdominal pregnancies (primary tubal pregnancies), two in the earlier group and one in the later. The latter patient was delivered of a child weighing 1,940 Gm. (4.25 lb.) that survived, the only fetal survival in the series. (This case has been previously reported.[8])

In the entire series, among patients given conservative surgical treatment, the associated pathological findings could be implicated only six times as a possible causative factor for the ectopic pregnancy. All of these six patients had some form of endometriosis of the tube.

Results

Mortality.—The one maternal death, which occurred in the early group, made the over-all maternal mortality 0.3%. The patient died on the sixth postoperative day of pneumonia which had developed as a complication of anesthesia. No maternal death occurred in the last 12 years under study.

Obstetric Outlook.—When a woman has once had an ectopic pregnancy treated by the most appropriate surgical method, what can be said for her obstetric future? The outcome in this series is shown in table 10.

Follow-up data were obtained on 101 patients in the earlier group. Of these, 37 had a total of 70 subsequent pregnancies. Among the 37 patients, 4 had one subsequent pregnancy each which ended in abortion; and 1 other patient had a single subsequent pregnancy which terminated as an hydatidiform mole. Of the 70 subsequent pregnancies, 13 were ectopic. Among the cases followed, 36.6% of the patients subsequently became pregnant. Of the subsequent pregnancies, only 74.2% were carried to term.

2	12	14
3	3	4
4	2	...
5	1	2
6	1	...
Total patients having subsequent pregnancies	37	47
Total subsequent pregnancies	70	77
(included ectopic pregnancies)	(13)	(6)

Among the later group a follow-up was obtained on 97 patients. Of these, 47 had a total of 77 subsequent pregnancies. Among the 47 patients were 5 who had only abortions after their ectopic pregnancies. There were six subsequent ectopic pregnancies in the group. If one considers only the group for which follow-up information was obtained, then 48.5% had at least one subsequent pregnancy. Of the total subsequent pregnancies in this group, 85.7% were carried to term.

The chances of a second ectopic pregnancy are of interest also. It has been stated that 3 to 4% of the patients who have had an ectopic pregnancy will have a second one.[9] During the 20-year period that we studied, 16 women had two ectopic pregnancies treated at the clinic. In addition, two other patients had their second ectopic pregnancies during the period of study, the first having been treated at the clinic previously. One other patient had her second ectopic pregnancy treated at the clinic after the termination of the study. This then makes 19 of the 306 patients who had two ectopic pregnancies treated at the clinic. Also, 15 patients in the group gave a history of an ectopic pregnancy treated previously elsewhere, thus making a total of 34 patients among 306, or an incidence of 11.1%. The period between ectopic pregnancies ranged from 8 months to 11 years, with an average of 3 years 5 months. Of the 19 patients treated at the clinic for both ectopic pregnancies, only five had full-term pregnancies between the two.

Summary

During the 20-year period 1935 through 1954, 322 ectopic pregnancies in 306 women were encountered at the Mayo Clinic. In comparing the experience in the first 10-year group with that in the second, we found the following factors essentially the same in the two groups: age, parity, initial complaints, incidence of abortion, the correctness of diagnosis in the pathologically proved cases of ectopic pregnancy, and the pathological diagnoses when findings were other than the clinically suspected ectopic pregnancy.

A tendency toward increasingly conservative surgery and more liberal use of blood transfusion was noted in the later group. Also noted in the later group was an increased number of women having subsequent pregnancies. The maternal mortality was 0.3%; no maternal deaths occurred in the last 12 years under study. The study suggests that the morbidity of appendectomy with surgical operations for ectopic pregnancy is no greater than with abdominal hysterectomy. If dilatation and curettage had been performed on all patients suspected of having ectopic pregnancy in our series, 18 intrauterine pregnancies that later reached term would have been interrupted.

SURGICAL MANAGEMENT OF THE TUBAL FACTOR IN INFERTILITY

Roy W. Cauwet, M.D., Menlo Park, Calif.

Sixty-nine patients with infertility due to tubal occlusion were treated by salpingolysis, salpingostomy at the fimbria, resection of the occluded part with reanastomosis, and reimplantation of the tube (when blocked near the cornu uteri) into the uterus. In all procedures, other than salpingolysis, the use of polyethylene tubing as a splint, to be left in place as long as three months, was an important part of the technique. Eighteen pregnancies (26%) have occurred after operation in the 69 women of this series. The use of polyethylene tubing has resulted in a greater frequency of tubal patency. However, in spite of patency, pregnancy does not occur often if the tubal wall has been badly damaged. Pregnancy will occur most often when damage is limited to peritubal adhesions. Diagnosis of peritubal adhesions may fail unless culdoscopy is utilized in women whose infertility is unexplained after the completion of the usual studies. Culdoscopy was necessary for diagnosis in 17 of the 35 women in this series with peritubal adhesions due to pelvic inflammatory disease or endometriosis. Forty per cent of the 35 women treated by salpingolysis have become pregnant.

Disturbances of tubal function have been reported in from 10 to over 50% of infertile women. Rubin,[1] in a collected series of 86,000 cases, found an incidence of 40%. Nonsurgical treatment has included repeated uterotubal insufflation, hysterosalpingography, and a combination of pelvic diathermy and cortisone therapy. Greenhill's survey of 1937[2] discouraged surgical treatment, as it showed that 818 plastic operations resulted in 54 pregnancies, or a 6.6% pregnancy rate. In 1950, using monkeys, Castallo[3] reported on tubal healing after resection when various substances were used as splints. Regeneration of the mucosa and muscularis occurred only when polyethylene was used, while other substances led to the formation of scar tissue. The advent of a suitable splint, in addition to general advances in surgery, resulted in a renewed interest. In 1951, Perl,[4] Wexler and coworkers,[5] and Hellman[6] described procedures utilizing polyethylene splints. Since then may others[7] have reported their techniques and results.

In the operations to be reported here, many of the technical variations already reported have been used. Sharp dissection, careful hemostasis, and gentle handling of tissues are essential. Proper instruments, such as curved iris scissors, Bishop-Harmon eye forceps, probes less than 1 mm. in diameter with one end threaded for transport of the polyethylene tubing, and mosquito forceps must be available. Bleeding is minimized by use of a tourniquet around the cervix and rubber shod clamps on the infundibulopelvic ligaments.

Sixty-nine patients with occluded tubes were operated on at Stanford University Hospitals during the five years ending June, 1957. Although many had contributory causes, only those patients were included in whom interference with tubal function was thought to be the primary cause of infertility. There were 38 private and 31 clinic patients. Their ages ranged from 20 to 38 years, with an average age of 30. Only one had been infertile for less than 2 years, the others from 2 to 15 years. The mean duration of infertility was seven years.

Previous infertility studies, age, and the duration of infertility contributed to the determination of the time interval and sequence of the various tubal patency tests. In general, tubal insufflation was used for screening. If negative, the test was repeated the following month. Salpinograms were obtained if tubal insufflation was persistently negative or if no apparent cause of infertility was found. Culdoscopy was done if there was doubt about blockage shown by salpingograms, if there was suspicion of endometriosis or pelvic inflammatory disease, or if infertility was still unexplained. Tubal patency was assessed during culdoscopy by injecting methylene blue solution into the uterus and observing it emerge from the fimbria. This was primarily useful in confirming the presence of interstitial or isthmic blockage when no other indication for laparotomy was found during culdoscopy. Location of the blockage site during laparotomy was aided by injection of dye in the same manner.

Treatment of Various Lesions

In general, four standard operative procedures were used to correct the various pathological lesions encountered. Briefly, these were salpingolysis, salpingostomy at the fimbria, resection of blockade and anastomosis, and intrauterine tubal implantation.

Instructor, Obstetrics and Gynecology, Stanford University School of Medicine, San Francisco.

Read before the Section on Obstetrics and Gynecology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

Peritubal Adhesions.—Thirty-five women had peritubal adhesions resulting from either endometriosis or inflammation extensive enough to envelope the fimbria and thus prevent the ovum from entering the tube.

Endometriosis: Endometriosis was found in 13 private patients. Two were Orientals, the others white. The diagnosis was suggested by complaints of dysmenorrhea, pelvic pain, and dyspareunia. Persistent retroversion, tenderness, adnexal masses, and nodules along the uterosacral ligaments were sought during bimanual examination. However, in 9 of the 13 the diagnosis was uncertain or unexpected to the extent that culdoscopy was performed. This failed in two cases due to dense adhesions which were found at laparotomy. In addition to salpingolysis, the procedures shown in table 1 were done as indicated. All endometriotic implants were excised by sharp dissection. Wedge resection was performed if the ovaries appeared cystic. Unilateral oophorectomy was done once because the tube on the same side was absent as a result of an operation for an ectopic pregnancy. Salpingo-oophorectomy was done in another instance because the tube was rudimentary. The uterus was suspended if there had been a persistent retroversion or if it appeared that the adnexa would then be held away from the site of previous adhesions. Pregnancy followed in 7 of the 13 women in this group. There were no ectopic pregnancies, two aborted, and the remaining five women delivered living infants.

TABLE 1.—*Additional Operative Procedures Done at Time of Tuboplasty*

Myomectomy	...	6	2	4

Pelvic Inflammatory Disease: Peritubal adhesions were due to chronic pelvic inflammatory disease in 22 women. Fourteen gave no history of postabortal, puerperal, appendiceal, or gonococcic infection. Four of 14 had positive salpingograms. In addition to salpingolysis, the procedures shown in table 1 were performed when indicated, as previously mentioned.

After all adhesions were freed, tubal patency was tested by injecting methylene blue solution into the uterus and observing its course through the tubes. Bilateral tubal patency was present in 7 patients and unilateral patency in 15 patients. Seven of the 22 became pregnant. Three of the seven with bilateral patency became pregnant. One had two ectopic pregnancies and the other two had term pregnancies. Four of the 15 with unilateral patency became pregnant, and all delivered living infants.

The obstructed tube was treated as shown in table 2. It does not appear that this additional effort produced any more pregnancies. Rather, if one tube is patent, it may be better to remove the obstructed tube and adjacent ovary so that ovulation will always occur on the side of the patent tube.

Fimbrial Closure.—Fourteen women had bilateral hydrosalpinges (10 private and 4 clinic patients). Salpingograms accurately demonstrated the sites of blockage, thus interstitial patency was evident in all. The tubes were repaired by excising the closed ends. The mucosa was everted to form a cuff which was sutured in place with 0000 absorbable chromic surgical (catgut) sutures. A splint of polyethylene tubing, 1.52 mm. in diameter, was threaded through the new ostium and brought out through the wall of the ampulla. The ends of the tubing were brought through the abdominal wall by threading them through 14-gauge needles. The splints were left in place from six days to three months. Currently, they are allowed to remain four weeks.

In 2 of the 14 cases the polyethylene tubing was brought out through the cervix. To accomplish this an anterior fundal incision was made in the uterus and a probe was passed through the fallopian tube by way of the uterine ostium. The polyethylene tubing was attached to the probe and pulled through the salpinx. Polyethylene tubing with an outside diameter of 0.965 mm. was used because normally the interstitial and isthmic portions of the tube are seldom greater than 1 mm. in diameter. Additional procedures were done as shown in table 1. Although nine patients achieved patency of one or both tubes, no pregnancy occurred.

Dilatation of blockage site and splinting	1	...
No further surgery	3	1
Total	11	4

* Unilateral blockade shown by dye injection.

Midportion Blockage.—Four patients had blockage of the midportion of the tubes, three resulting from tubal ligation for sterilization. In these an anterior fundal incision was made and probes were passed through the uterine and abdominal ostia of the tube to the obstruction site. After the blockade was excised, the probe through the uterine ostium was passed through the rest of the tube and out the fimbrial opening. Polyethylene tubing, 0.965 mm. in diameter, was threaded on the proximal end of the probe and pulled after it. The other end of the splint was passed out through the cervix. If any difficulty occurred at this point, the splint was attached to a ureteral catheter which was passed with ease. Later, the splints were fastened to the cervix by stainless steel wire and left in place for about four weeks. The serosal surface of the two segments of fallopian tube were approximated with several 0000 absorbable chromic surgical (catgut) sutures. Patency resulted in three of the four women and all three became pregnant. One aborted, one had an ectopic pregnancy, and the other was delivered near term by cesarean section.

Isthmic and Interstitial Blockage.—In 16 patients blockage was in the isthmic and interstitial parts of the tube. In two of these it followed previous cornual resection for sterilization after cesarean section. In six the cornual blockage was excised and the patent portion of the tube was bisected for a short distance and implanted in the uterus. Small polyethylene splints were brought out through the cervix and left in place as long as three months. Patency resulted in four women. The only pregnancy went to term and the infant was delivered spontaneously.

In the remaining 10 an attempt was made to preserve tubal length, and the patent end of the tube was not implanted. Rather, it was attached to the uterine wall in continuity with a fistulous tract created by passing a probe through the uterine ostium of the tube and the uterine wall. A polyethylene splint was passed through the tube, the fistulous opening, and the cervix and was left in place up to three months. The serosa of the tube was attached to the uterus with 0000 absorbable chromic surgical sutures. Patency occurred in two instances, but there were no pregnancies.

Comment

The incidence of tubal obstruction will vary according to the frequency and kinds of tubal function tests utilized. Ostry[8] reported that, of 44 patients who had tubal obstruction by repeated tubal insufflation and hysterosalpingograms, 31 showed patency by insufflation with the patient under anesthesia. Jeffcoate[9] found that 43 of 116 insufflation tests and 13 of 86 salpingograms were erroneous. In 32 cases, blockage demonstrated by both insufflation and salpingograms proved misleading in five instances. Stallworthy[10] stated that the true incidence of tubal occlusion is about 10% and that higher figures quoted by others are due to functional occlusion. This may be why Buxton and Southam[11] reported that, of 67 patients with the diagnosis of tubal obstruction, pregnancy occurred in 5, or 7.5%. Extreme care must be taken not to operate on women whose tubes are actually patent.

The patients who were helped most frequently were those with peritubal adhesions. Of the 35 women treated by salpingolysis, 14, or 40%, subsequently became pregnant. The presence of peritubal adhesions was suggested by delayed shoulder pain after tubal insufflation and atypical distribution of the opaque medium in the peritoneal cavity. However, these signs were inconstant and culdoscopy was often necessary for diagnosis. Kelly and Rock[12] reported that tubo-ovarian adhesions were present in 34% of 417 infertile women in whom culdoscopy was successful. In 246 women with unexplained infertility subjected to culdoscopy, pathological lesions to account for infertility were discovered in 84, or 34%.

Peritubal adhesions were due to endometriosis in 13 of the 35 women in this group. The facts that all 13 were Oriental or white and private patients were consistent with the low incidence of endometriosis reported by large charity hospitals, particularly those with a high percentage of Negro patients.

Although endometriosis is found in only 4% of infertile women, it is a prominent factor in the group with infertility that is left unexplained after completion of the usual diagnostic studies. Recognition of the presence of endometriosis is particularly important because more than 50% of women with this disease will become pregnant after conservative surgical treatment. Even with the extensive involvement in the 13 patients with endometriosis in this series, 7 have become pregnant since surgery.

Hydrosalpinx produces the most extensive tubal damage. Fimbria become unrecognizable, and pressure flattens the mucosa and thins the muscularis. Even so, Siegler and Hellman[13] reported a 20.3% pregnancy rate in 891 collected cases. Rock and co-workers[7d] had a 24% pregnancy rate in such patients when they protected the newly formed ostium with a polyethylene hood that was removed at a second operation. In our series, the establishment of tubal patency in 9 of the 14 women was noteworthy, but no pregnancies resulted.

Animal studies[14] have indicated that normal implantation does not occur unless the endometrium corresponds closely in maturation to that of the implanting blastocyst. As others have suggested, it would seem that shortening of the tube, with early presentation of the blastocyst to the endometrium, might be the cause of the discrepancy between the patency and pregnancy rates. On the basis of Castallo's[3] experimental work that showed the tubal wall would bridge a gap, preservation of tubal length by utilization of a uterine fistula was attempted. The results in 10 cases (2 patent, none pregnant) do not compare favorably with the reported results of tubal implantation.

In 1956, Siegler and Hellman[13] reported the results of a survey of 2,285 tubal plastic procedures. Only operations done by surgeons who had performed at least 10 of these procedures were included. The over-all results of their study are shown in table 3 and are compared to the results of the Stanford series. The total pregnancy rate of 26%, 18 of 69 women, in the Stanford series is similar to the 22% rate in the Siegler and Hellman study. Both series show an increased frequency of ectopic pregnancy.

Siegler and Hellman stated that if pregnancy does not follow within a year of surgery, the operation should be considered a failure. Fourteen of the 18 pregnancies in the Stanford series did result within a year: 7 within 3 months, 2 within 6 months, and 5 within 12 months. However, two did not occur until after one year, and two others until after two years. Thus, even after a year, if the tubes are patent, the patient may be advised that pregnancy is still possible.

TABLE 3.—*Outcome of Tubal Operations in Stanford Series Compared with World-wide Survey Series*

Procedure	Operations, No.	Pregnancies Achieved: Ectopic	Abortion	Live Births	Total Pregnancies
Salpingolysis	35	1	2	11	14(40%)
Salpingostomy	14	0	0	0	0
Resection and anastomosis	4	1	1	1	3
Tubal implantation	16	0	0	1	1
Total	69	2	3	13	18(26%)
Siegler & Hellman Survey[13]	2,285	47	79	378	513(22%)

Five of the 69 patients had had tubal ligation for sterilization. Three were sterilized after cesarean section at 25 years of age or less. When this procedure is done in young women, there is a greater risk that it may be regretted in later years. This risk should be considered whenever tubal ligation is contemplated.

Summary

Sixty-nine women in whom the tubal factor was considered to be the primary cause of infertility were subjected to various types of tuboplasty, and 18 (26%) became pregnant. Of 35 treated by salpingolysis, 14 became pregnant. Fourteen were treated by salpingostomy at the fimbria and by polyethylene splints. Tubal patency resulted in nine, but none became pregnant. Twenty were treated by resection of the blocked area and polyethylene splints or tubal implantation and splints. Nine of these have patent tubes, and four became pregnant.

Proper tubal function requires a normal muscularis and mucosa as well as a patent lumen. Polyethylene tubing has resulted in a greater frequency of tubal patency. However, pregnancy does not occur often in spite of patency when the tubal wall has been badly damaged by disease. Pregnancy will result most frequently after surgery when damage is limited to peritubal adhesions. Culdoscopy may be necessary for the diagnosis of these adhesions.

CHRONIC VESICULOPROSTATITIS—A REORIENTATION

Abel J. Leader, M.D., Houston, Texas

The term vesiculoprostatostasis is suggested for a complex of symptoms and findings occurring in many men and is believed to constitute a definite clinical entity. Probably more than 35% of all men over the age of 35 years have this condition. It consists of a variety of disturbances of urinary, sexual, and psychic functions; alterations in the size, shape, and consistency of the prostate and seminal vesicles; and the inconstant and quantitatively variable finding of pus in the secretions expressed from these structures. The finding of pus cells in the absence of recognizable pathogenic organisms justifies neither the diagnosis of infection nor the term prostatitis, which implies a bacterial cause. Anti-infective drugs in the uncomplicated case are useless. The primary cause of vesiculoprostatostasis is repeated sexual excitation without physiological discharge of secretions. Local treatment aims at decongestion of the seminal vesicles and prostate by periodic vesiculoprostatic massage. Relief of symptoms follows in a high percentage of patients. Cure is possible, however, only insofar as causes can be eliminated. Since the most common cause is marital sexual maladjustment, the cure may be relatively simple in some cases; in others the problem may be so deep-seated and complex as to lie in the sphere of the psychiatrist.

Chronic vesiculoprostatitis is regarded as a distinct clinical entity of exceedingly common occurrence. It is classically defined as a pyogenic infection of the prostate and seminal vesicles. Recently, certain of the traditionally accepted concepts relative to the nature, etiology, and pathogenesis have been questioned. It is the purpose of this paper to suggest that the condition is more logically to be considered a functional derangement of the prostate and seminal vesicles resulting from the stasis of retained secretions. It is also suggested that pyogenic infection, when actually present in either the acute or chronic form, is a complication of a preexisting state of congestion in these structures.

Although the infection has been thought to be primary in the prostate, it has also been thought that the seminal vesicles are almost always involved because of their proximity and common lymphatic drainage. The term vesiculoprostatitis has been therefore considered more accurately descriptive of the process as a single entity. The incidence of chronic vesiculoprostatitis is high, and it is estimated that more than 35% of all men over the age of 35 years can be shown to have the disease.[1] The diagnosis is usually made on the basis of a rather characteristic symptom complex, alterations in the size, shape, and consistency of the prostate and seminal vesicles, and the pus content of the secretions expressed from these structures.

Although it is generally believed that the disease is due to infection, it has long been known that only occasionally is the clinical diagnosis supported by laboratory evidence. In most instances, cultures of the prostatic and vesicular secretions show no growth; in others, the bacterial flora identified may consist of two or more organisms of doubtful pathogenicity. In a recent study, O'Shaughnessy, Parrino, and White[2] were able to obtain positive cultures from prostatic fluid obtained endoscopically from only 3 of 68 men thought to have the disease. In only one of these was a known pathogen identified. Based on a study of the prostatic secretions from 760 men, the same authors concluded that the finding of pus cells in the prostatic fluid is not sufficient to substantiate the diagnosis of prostatitis or to explain the symptoms of which patients thought to have such disease complain.

Similarly, efforts to correlate the alleged high clinical incidence of chronic vesiculoprostatitis with histopathological changes in the prostate and seminal vesicles have not been successful. Calams,[3] studying the vesicles from 161 routine autopsies for evidence of inflammation, concluded that histopathological evidence of such disease is only rarely observed. When seen, it was usually associated with prostatic carcinoma and prostatic and periprostatic abscesses. Our studies of seminal vesicles removed at autopsy and at operation have similarly disclosed singularly few instances of inflammatory change.

Also, it has been pointed out, particularly by Robbins,[4] that the histopathological criteria for inflammatory changes due to infection which have been employed by many pathologists are inaccurate. When more stringent criteria are used, the incidence of "chronic prostatitis" is found to be much less than is frequently supposed. He points out that in the normal senile changes in the prostate aggregations of lymphocytes are prone to appear in the fibromuscular stroma. All too often, he says,

---

Read before the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

such nonspecific aggregates are diagnosed as "chronic prostatitis" even though the pathognomonic inflammatory cells (i. e., the macrophages and the neutrophils) are not present. The term "chronic prostatitis" should be restricted, he believes, to those cases in which there is clear-cut evidence of persistent smoldering infection in the form of neutrophilic infiltration, along with other mononuclear cells, as well as evidence of destruction and fibroblastic proliferation.

Even where such evidence is present, the immediate relationship to infection has not been clearly demonstrated. Most often, Gram-stained tissue sections fail to show the presence of bacteria. While it is common to think only of bacteria or other living agents as the cause of inflammation, it is important to remember that many nonliving agents, such as heat, cold, radiant energy, electrical or chemical stimuli, or simple mechanical trauma such as pressure, may also act as destructive influences and evoke inflammatory responses. Further, when such agents are sufficiently violent to cause the death of tissue cells, the necrotic substances released from the dead cells also serve as injurious agents and add to the inflammatory response.

When they were first employed, much was expected of the antibiotics and the sulfonamides in the treatment of patients with chronic vesiculoprostatitis. Their failure to alter the course of the disease materially or to modify the symptoms and findings was soon apparent. Had the process been truly a pyogenic infection, at least a reasonable degree of success might have been realized from this form of treatment, but this did not prove to be the case. Conversely, when the disease is treated by local massage to promote drainage of the retained secretions from the involved vesicles and prostate, relief of symptoms follows in a high percentage of patients.

From the foregoing, it appears reasonable to believe that what is basically involved is a functional inability of the prostate and seminal vesicles to empty themselves of their secretions. The back-pressure produced by the accumulating retained secretions gives rise to congestive inflammatory changes and is responsible for both the symptoms and the physical findings considered characteristic of the disease. After these congestive changes are established, the vesicles and the prostate are vulnerable to invasion by pyogenic organisms with the production of true suppurative disease. I am of the opinion that acute and chronic pyogenic disease of the prostate most often occurs as a complication of preexisting congestive changes.

This condition of stasis-congestion as a clinical entity has been previously recognize by Barnes.[5] He referred to the disease as "toxic hyperplasia of the prostate" and defined the condition a morbid state in which there is distention of the and with an excessive amount of prostatic fluid w[illegible] has specific toxic properties. He believed, too, that the seminal vesicles are similarly involved to a greater or lesser degree. Barnes indicates that, while other authors [6] had suggested the existence of a chronic noninfective congestion of the prostate which predisposed to infection in that organ, none had previously attributed the general systemic and localized symptoms to the toxic effects produced by the absorption of this excessive secretion.

If stasis and congestion are to be regarded as basic mechanisms in this condition, the term vesiculoprostatitis seems unsuitable since through use it has come to mean inflammatory disease of pathogenic bacterial etiology. In its place, the term vesiculoprostatostasis is suggested for clinical use, since it more nearly describes the true state of affairs.

Etiology

In speaking of the functional disturbances of micturition in women, Smith has referred to the bladder as the mirror of woman's soul.[7] Similarly, the state of a man's prostate and vesicles may well reflect his sexual activity. Thus it may be said quite seriously that vesiculoprostatostasis represents the difference between a man's sexual life and what he consciously or subconsciously would like it to be. The enormous influence of the psyche on man's outlook, his attitudes, and his physical well-being is well known. One has only to remember the storms and stresses of adolescence to appreciate that sexual frustration can be productive of distressing symptoms. The "stone-ache" of high school and college days that commonly followed upon sexual excitation without gratification and the manner in which it was relieved remains vivid in the memory of many men. In later life, this symptom of pain in the testis has sometimes been referred to as "testicular neuralgia" and may be of such character and duration as to suggest epididymitis as the cause. In both instances, the symptom is a reflex manifestation of overdistention of the seminal vesicle. In the adult, the pain or discomfort may be referred for a variable distance along the cord structures, although it may not extend to the testis itself. Very often, stripping the seminal vesicle of its retained secretions provides prompt relief of symptoms. It appears that the seminal vesicle, reacting to the stimulus of anticipated sexual activity, and ready to perform its function according to Nature's plan, but having no brains and no morals, accepts disappointment with poor grace. The immediate cause and effect relationship demonstrable here appears to deny the contention of the psychiatrist that "guilt feelings" alone are responsible for such symptoms. Alleged to be prominent among these is the feeling of guilt over masturbation. Although the psychiatrist is willing to admit that the urologist is very frequently successful in the treatment of such patients, he contends that the relief obtained is in effect produced by the patient's subconscious belief that he is expiating his earlier "sex offense" through the actual physical suffering which he must endure during the course of his treatment. To the conscientious urologist who includes the majority of such patients among his therapeutic successes, such a devious explanation is quite unacceptable.

The term "faulty sexual hygiene" is commonly employed to cover a number of irregularities in the sex life of the individual. It seems to imply that the continued or repeated unphysiological sexual practices producing chronic congestive changes in the prostate and vesicles can be modified or eliminated solely as a matter of discipline by the individual involved. This is probably true of "coitus interruptus" in which the penis is withdrawn from the vagina immediately prior to ejaculation in order to prevent impregnation. In such event, the evacuation of the prostate and vesicles remains incomplete, and it is generally acknowledged that when the practice is continued, congestive changes are a common consequence. Excessive sexual excitement without physiological gratification, as in "necking" or "petting," excessive masturbation, and a morbid interest in pornography are also considered responsible for such congestive changes.

Clinical experience seems to indicate that the principal cause of vesiculoprostatostasis is none of the foregoing; it is marital sexual maladjustment. This may be confirmed through tactful questioning by the sympathetic physician. In such event, the circumstances that lead to the development of congestive changes are not necessarily of the patient's own making, nor can he modify or eliminate them by himself. Sexual discord in the married couple has many causes, but the moral code of a monogamous society interdicts extramarital relationships; the great majority of men will not violate it but will instead make the best of what they regard as bad bargains. If it is true that many women, if not actually the majority as stated by Kroger and Freed,[8] are either frigid or indifferent to the need for sexual expression, the problems imposed by the thwarted sex drives of the men married to these women seem destined sooner or later to become manifested clinically in the syndrome of vesiculoprostatostasis.

Symptomatology

Ostensibly, the primary presenting complaint of the patient with vesiculoprostatostasis is pain. As the physician takes the history, he is soon aware that the patient is equally or more concerned with his failing sexual powers, although he may not associate the two complaints. Backache is most common; this is manifested as a dull, continuous sensation of pressure in the sacroiliac area which is not modified by position, motion, orthopedic devices, or muscle relaxants. A "tired feeling" in the lower part of the back, for which the patient seeks relief by a characteristic hyperextension of the spine, is a frequent complaint. Pain in the groins or suprapubic area, possibly radiating to the testis, is a common symptom implicating many an innocent varicocele and dilated inguinal ring. This pain is dull, continuous, and is sometimes described as mildly nauseating. On questioning, the patient frequently remembers that the pain closely resembles that of the "stone-ache" of his adolescence. A sense of perineal fulness, or of a "fluttering" in the rectum is sometimes described. The stripping of the vesicles and the prostate so frequently improves these symptoms that when such relief is not soon obtained the validity of the diagnosis is open to question.

Sexual complaints range from premature ejaculation to complete impotence. Loss of libido in varying degree is common. In this connection, it is surprising how many men in the late 40's accept their diminishing sexual powers as a natural consequence of aging. Occasionally, the patient complains of a mucoid urethral discharge, particularly noticeable in the morning, and especially after a bowel movement. Such a discharge does not originate in the urethra, but is thought to represent an overflow from the distended vesicles and prostate of the same order as the paradoxical incontinence associated with a chronically distended urinary bladder. Referred to as "gleet" or prostatorrhea, the discharge is disturbing to the patient and the physician alike because it may be mistakenly considered to be of venereal origin.

Urinary symptoms are not prominent, although the patient may complain of mild degrees of frequency, urgency, burning, and a diminution in the force of his urinary stream. Peculiar itching sensations in the urethra are sometimes experienced. Most often, the patient is unaware of any alteration in his voiding habits, even when subsequent urethroscopy discloses a significant degree of bladder neck contracture or granular changes in the posterior urethral mucosa.

General complaints include those of weakness in the thighs and legs, easy fatigability, lethargy, blunting of interest and mental facility, excessive anxieties, tensions, and tension headaches, and nervousness. Such symptoms have been attributed by Barnes[5] to the toxic effect of the reabsorbed prostatic and vesicular secretions. He was able to show that normal human prostatic fluid as obtained by prostatic massage has a definite, constant, and marked pharmacological action which is not identical with any other substance now known. Another explanation is that such systemic symptoms represent the combined effect of the functional disorder and the feelings of frustration and rejection engendered by the sexual problem.

Diagnosis

The diagnosis of vesiculoprostatostasis is based on the typical history, the symptoms, the findings, and the therapeutic response to decongestion by prostatovesicular massage. The expressed secretions may contain no abnormal elements, but, even if pus cells are found, the diagnosis remains valid. Many urologists examine the expressed secretions after each treatment for the purpose of grading the pus content; such quantitative estimations have no appreciable value either in diagnosis or as a measure of therapeutic response.[2]

The rectal findings are helpful in establishing the diagnosis but are not always characteristic. The prostate may be moderately enlarged and have what is described as a "boggy" or a "mushy" consistency, differing in this respect from the normal prostate which feels firm, or the hypertrophied prostate which is uniformly elastic. More often, the seminal vesicles are enlarged, cystic, and may be moderately tender. Not uncommonly, they are so enlarged that they obscure the outlines of the underlying prostate. The expression of copious quantities of secretion from the prostate and vesicles is almost pathognomonic of the condition.

Treatment

The treatment of vesiculoprostatostasis is largely symptomatic. The treatment of causes and the problems of prevention are enormous in magnitude and are largely outside of the province of the urologist. Although the physician may make suggestions that aim at eliminating causes, when these involve the failure of the husband and wife to effect a mutually satisfying sexual relationship, the prospects for permanent cure are reduced. In such event, the help of a psychiatrist may be required to resolve the basic causes of the conflict. With his special techniques, he may be able to rid the wife of her phobias and fears concerning sexual expression, and may provide her with the insight she needs to bring her to the acceptance of her responsibilities as a sexual partner. Other factors may also work against a happy solution. These include deep-seated psychiatric disturbances on the part of either husband or wife, organic diseases, aberrant religious convictions, and the like.

In the treatment of the male patient, sympathy and understanding on the part of the urologist, a carefully taken history, and a logical easily understandable explanation of the nature of the process responsible for the symptoms are indispensable to success. The very nature of the questions asked by the physician, to the majority of which the patient finds himself giving affirmative answers, serves to inspire confidence. The reassurance that he is suffering from no serious organic disease is important to the patient, for with understanding he can at least learn to live with his problem.

Patients with vesiculoprostatostasis are frequently dismissed from serious consideration as neurotics, but the sympathetic physician appreciates that neurosis frequently results from overtaming of the instinctual impulses and that frustration is frequently responsible for organic malfunction. In this sense, at least, the urologist has a dual role, and psychotherapy is an important component of the treatment. The physician who tells the patient with vesiculoprostatostasis that there is nothing wrong with him denies to him both the relief of symptoms and the peace of mind that comes with understanding.

Local treatment aims at the decongestion of the seminal vesicles and the prostate by periodic vesiculoprostatic massage. The details of such treatment are available in any standard urology textbook and will not be repeated here. Initially, it may be necessary to strip the prostate and vesicles of their retained secretions at four to seven day intervals for two weeks or longer. Thereafter, the treatment is repeated at weekly intervals until the patient is free of symptoms. The periods between treatments are then increased, and the patient is seen at intervals of one to three months depending on the continued freedom from symptoms, the consistency of the prostate and vesicles, and the quantity of fluid expressed. After several treatments at such intervals, the patient is dismissed and told to return if symptoms recur. In such event, one or more massages may again make the patient asymptomatic. The patient is frankly told that the prospects for permanent cure are small, but, if the true nature of the process has been explained to him, there is usually no difficulty in securing his complete cooperation for any regimen of treatment.

Endoscopic investigation and urethral instrumentation are employed only if there are concomitant urinary complaints that clearly indicate the need for such efforts. Estrogen therapy has been employed to reduce prostatovesicular congestion, but it seems advisable to restrict this therapy to the management of the patient acutely uncomfortable as a result of sexual gluttony.

Comment

The conventional approach to some of the common disorders of prostate gland and seminal vesicles as manifestations of infection results in many inconsistencies that cannot be explained satisfactorily. It has not been possible to reconcile the exceedingly common incidence of an entity thought to be due primarily to bacterial invasion with the relative rarity of demonstrable histopathological evidence of such involvement. Furthermore, bacterial cultures of the secretions of the glands thought to be involved by infection have proved disappointing, as has the use of the antibiotics and the sulfonamides in treatment.

If it is recalled that inflammatory changes may be due to other than living agents such as bacteria, it is then possible to explain the symptom complex previously referred to as chronic vesiculoprostatitis as a functional derangement of the prostate and seminal vesicles. This results from a failure of the glands to empty themselves of their secretions, and the resultant stasis of the secretions and the back pressure they produce are responsible for the symptoms and findings. The term vesiculoprostatostasis therefore seems more appropriate for purposes of clinical discription than does the term vesiculoprostatitis, since the latter has come to denote a bacterial causation.

The primary cause of vesiculoprostatostasis is repeated sexual excitation without physiological gratification. This is most common as a result of marital sexual maladjustment. Factors such as "coitus interruptus," sexual excesses, alcoholism, unrewarded "necking" and "petting," and a morbid interest in pornography contribute also in varying degree to the development of the congestive state.

The principal aim of treatment of the urologist is the relief of symptoms caused by the congestion. Cure is possible only insofar as the elimination of the causes can be effected. When the problems of marital sexual maladjustment leading to the development of congestive disorders of the prostate and vesicles in the husband are relatively simple, the superficial psychotherapy given in association with urologic treatment may be most helpful. When the causes are more complex and deep-seated the problem lies in the psychiatrist's sphere of interest.

The congestive changes in vesiculoprostatostasis are thought to predispose the prostate and seminal vesicles to invasion by pathogenic bacteria with the development of true suppurative inflammatory disease.

POSTOPERATIVE INTRA-ABDOMINAL BLEEDING.—The common elements associated with massive postoperative bleeding . . . are (1) major surgery in a debiliated patient (with malignancy), (2) evidence of impaired wound healing, (3) intra-abdominal infection, (4) a biliary or pancreatic fistula, (5) severance and ligation of a major branch of the hepatic artery or other component of the celiac axis, and (6) hemorrhage, usually occurring late in the postoperative period. One can envision several technical failures as contributing to the catastrophe described: (1) fine suture material, which was tied too tightly; (2) injury of the vessel wall in an attempt to leave only a short stump of the arterial branch being ligated; (3) injury to the arterial wall during the placement of a suture ligature. In the reported cases, all of the ligatures were single or double ties of 000 silk. That there was not direct involvement of a single surgeon in more than one case seems to obviate the importance of a personal factor. . . . The most important elements were . . . a failure of healing as a result of malnutrition and the presence of infection or bile or pancreatic juice at the site of arterial ligation. . . . Secondary hemorrhage was commonest in infected wounds and . . . as in the cases reported in this paper, [it] generally occurred as two separate episodes, the first a small initial hemorrhage two or three days later. The treatment of choice was described as ligation of the vessel; however, recent advances in vascular surgery might modify this opinion. Hemorrhage from the carotid arteries associated with complications of radical neck dissection is well known to head and neck surgeons. In general, this misfortune does not occur unless the wound flaps have remained unhealed, a fistula has developed below the wound flap, or an abscess has developed immediately adjacent to the artery.—G. E. Moore, M.D., Ph.D., and M. J. Payne, M.D., Intra-Abdominal Hemorrhage following Abdominal Surgery, *A. M. A. Archives of Surgery,* August, 1958.

PHYSICIAN RELATIONSHIPS

PROBLEMS RELATED TO PUBLIC HEALTH, CLINICAL PRACTICE, AGING, AND LONG-TERM ILLNESS

Bruce Underwood, M.D., Washington, D. C.

Physicians working as health officers in state and local governments should be full partners with other physicians, including those in private practice and in organizations that concern themselves with the care of the sick and prevention of disease. A closer relationship between public health practice and clinical practice is desirable. Public health, occupational medicine, and preventive medicine are closely allied. The need for cooperation between the public health physician and the private physician is especially evident in the field of old age and chronic illness. A civilized community is marked by the extent to which time and money are voluntarily committed to the proper care of the very young, the very old, and the infirm. Individuals can do a great deal, but organized effort is called for as well.

Let us think about the relationship of physicians in private practice to those who are not in private practice, the relationship of physicians in public health practice to physicians in clinical practice, and some relationships with other professional workers in the field of aging and long-term illness.

Public Health and Clinical Practice

There are such questions as: Is the American Medical Association more interested in physicians in private practice than it is in those who are not in private practice? What is the real status, in the American Medical Association, of physicians teaching in our medical schools, physicians in industry, physicians in the armed services, physicians in the field of insurance, physicians in research, physicians in government service of all kinds, and all other non-fee-for-service physicians? There are many physicians in all kinds of medical administration and health administration activities today. Are they full partners with other physicians? Are they adequately represented in the House of Delegates of the A. M. A.? What about physicians in the field of public health? Are they welcome at medical society meetings? Are they accepted and respected as physicians?

I was a member of the House of Delegates from 1950 to 1955. In 1950 several members of the House of Delegates were state and local health officers. In 1955 I was the only public health physician left in the House, and I was there by virtue of my position as Secretary and General Manager of the Kentucky State Medical Association. How many "working" health officers of the United States are members of the House of Delegates today?

I have been concerned for some time with the question of whether or not the American Medical Association truly serves the interests of all physicians or whether it places undue emphasis on the interest of physicians in private practice. It was with these thoughts in mind that I suggested to the Board of Trustees of the American Medical Association that the Association study the current relationship of doctors of medicine who are not in private practice to those who are in private practice. It was my thought that the scope and extent of the problems involved in working and organizational relationships be determined. I further suggested that such action as may be needed and desired be taken to strengthen the American Medical Association as an organization for all doctors of medicine. Such a study is currently being made.

Although the problems that relate to the various groups of physicians who are not in private practice should be studied, let us consider the subject for a little while from the standpoint of the public health physician and the Section on Preventive Medicine. Should there be a separate section on "public health"? Many public health physicians think there should be. However, in discussions with the Council on Scientific Assembly, the question arose as to how many public health physicians would attend its sessions. The primary consideration is whether or not one section can adequately serve the interests of physicians in public health practice and physicians in such branches of clinical medicine as occupational medicine, aviation medicine, and preventive medicine.

Perhaps the name of the Section will throw some light on the subject. In 1859 the American Medical Association authorized a "Section on Medical Jurisprudence and Hygiene." Over the years the name of this Section has been changed as follows: 1859, Section on Medical Jurisprudence and Hygiene; 1865, Section on Medical Jurisprudence, Physiology, and Hygiene; 1872, Section on State Medicine; 1873, Section on State Medicine and Public Hy-

---

Chairman's address, read before the Section on Preventive Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

giene; 1879, Section on Medical Jurisprudence, Chemistry, Psychology, State Medicine, and Public Hygiene; 1880, Section on State Medicine; 1900, Section on Hygiene and Sanitary Science; 1908, Section on Sanitary Medicine; 1909, Section on Preventive Medicine and Public Health; 1922, Section on Preventive and Industrial Medicine and Public Health; and 1955, Section on Preventive Medicine.

The development of the American Board of Preventive Medicine and the American College of Preventive Medicine must be considered and also the development of the American Association of Public Health Physicians. This latter organization represents the "working" health officers of the country as its primary interest.

A closer relationship between public health practice and clinical practice seems indicated. Perhaps physicians in clinical practice need a better understanding of and interest in the problems of public health practice. Most physicians in public health practice consider themselves to be physicians first—physicians specializing in public health practice. We consider the community as our patient. We diagnose and treat communities. We try to help restore communities to health and to maintain them in a healthy condition. The practice of public health is different from the practice of clinical medicine because our patients are different. They have different needs and require different skills and techniques to meet their needs.

For over seven years I served as state commissioner of health and secretary and general manager of the State Medical Association in Kentucky. It was my experience that physicians in the clinical practice of medicine usually did not fully understand what was involved in the modern practice of public health. On the other hand, I have never known a physician in the clinical practice of medicine who did not become an enthusiastic supporter of physicians in public health practice if he had an adequate opportunity to know and participate in the solution of community health problems.

It is my hope that the physicians in clinical practice will, to an ever-increasing degree, come to understand and, along with public health physicians, provide the leadership in the field of community health that the public so much desires and expects.

As a result of these beliefs and hopes, I requested that the Board of Trustees of the American Medical Association also give special study to the problem of providing leadership in the extension and strengthening of community health services throughout the nation. Inherent in such a study are the problems of developing a mutually acceptable definition of public health practice, providing leadership for all governmental health and medical activities, and a consideration of the many public health activities of various nongovernmental health agencies and groups. This study, too, is currently being made. I hope that it results, among other things, in the formation of a council on public health practice in the American Medical Association.

Aging and Long-Term Illness

The foregoing discussion concerns problems involved in the relationship of physicians in private practice to those who are not in private practice, especially the relationship of public health practice to clinical practice. Now let us consider some relationships involved in the field of aging and long-term illness. Nothing more clearly illustrates the need for and the opportunity for cooperation between the public health physician and the private physician.

Health-related problems arise in such areas as recreation, counseling, adequate housing, and the development of facilities for long-term care. Organized home care programs are being developed, as are such community services as "meals on wheels" and homemaker services, to enable our older citizens and the chronically ill to live at home as long as possible and to maintain a state of "self-help" as much as possible. The whole field of medical rehabilitation for the aged and chronically ill is also rapidly developing, and, as it does, we are increasingly aware that no single discipline can solve all the problems of aging. Medical social service is coming into its own in this field, as in others. Medicine is doing a marvelous job of physical rehabilitation. But all too often, after an excellent job of physical rehabilitation, we find the individual cannot find a job or has no adequate home to which to return.

An 83-year-old man had a cerebrovascular accident. After several weeks in the Institute of Physical Medicine and Rehabilitation, the man was restored to a sufficient degree of self-help to enable him to go home. That is, he was physically able to go home. However, he had no home. The medical social service department had been working on the problem, but at the last minute the couple with whom the man had been staying changed their minds and said, "No! we don't want him back. The medical social service department then had to try some other arrangement. They called the man's son in Chicago. The son said, "Let me think about it." A few days later the son, without even visiting his father or finding out what his physical condition was, said, "No, I can't keep him."

Are we as physicians doing all we can to help improve the care of individuals in nursing homes and homes for the aged? There are many complaints to the effect that "we can't get our physicians to help us—they just are not interested." On the other hand, there certainly is a growing awareness of and interest in this problem on the part of the physicians of the country. The Joint Council to Improve the Health Care of the Aged has recently been formed.

This council was formed by the American Medical Association, the American Dental Association, the American Hospital Association, and the American Nursing Home Association.

The problems of the chronically ill and aged in institutions are great. A survey[1] of the proprietary nursing homes of the country in 1954 revealed that there were 25,000 nursing homes in the United States with 450,000 beds. Of these homes 91% were proprietary, 6% were voluntary, and 3% were publicly owned. A survey[2] of 13 states revealed that of the patients in proprietary nursing homes (1) the average age was 80 years, (2) less than one-half could walk alone or with the aid of a crutch or cane, (3) over half were mentally disoriented at least part of the time, (4) one-third were incontinent; and (5) one-third of the homes had neither a registered professional nurse nor a licensed practical nurse on the staff.

Are we concerned about these problems? Are we doing all we can? Are we as physicians providing the leadership that is needed? As physicians we cannot solve all the problems by ourselves, but we can do a great deal in cooperation with others. The administrators of the homes and others interested in the improvement of the care of individuals in nursing homes and homes for the aged are eager for our assistance. In addition, we have obligations that go beyond the field of public health and clinical practice. I am thinking of such biblical quotations as "Inasmuch as you have done it unto the least of my brethren, you have done it unto me." "Do unto others as you would have others do unto you." "You shall love your neighbor as yourself." "Am I my brother's keeper?" "If you do not love your brother whom you have seen, how can you love God whom you have not seen?"

I am also reminded of a statement by Dr. A. L. Chapman, chief, division of special health services, Public Health Service, who said: "Why bother about nursing homes and homes for the aged? Oldsters, most of them existing on meager incomes, have little bargaining power." The question then is bound to arise, "Why spend so much time and money caring for them?" Dr. Chapman said, "The answer, if you believe in it, is a simple one: The hallmark of civilization is a voluntary commitment of time and money to make sure that oldsters, youngsters, and the infirm are not denied whatever benefits and privileges a humane society can endow them with."

I recommend that the Section on Preventive Medicine give special consideration to these problems. The Section should have one or more special committees to participate in the study that is being made by the American Medical Association. At the very least, the Section in some way should communicate its views to the Committee that is considering these problems. We, as individuals, can do a great deal, but some action by the Section as a whole is indicated.

SALICYLATE INTOXICATION.—Until . . . 1955 . . . the treatment of salicylate poisoning was largely symptomatic. Gastric lavage should be performed in the hope of recovering some of the ingested salicylate. In the alkalotic stage fluids should be administered in the form of glucose in water. Small doses of sodium bicarbonate are recommended by some authors because bicarbonate increases the renal excretion of salicylates and also prevents too great a lowering of the bicarbonate reserve. The danger of large doses would be the aggravation of the alkalotic state, and some authors recommend that no bicarbonate be given until a state of acidosis exists. Once the patient has become acidotic, intravenous injection of sodium lactate is the preferred form of therapy. This was first introduced by Williams and Panting in 1937 and since that time has been standard treatment for salicylate poisoning. . . . Schreiner and co-workers reported a case of acetylsalicylic acid poisoning treated by dialysis with the artificial kidney. The initial salicylate level was 90 mg. per 100 cc. and was reduced by 57 mg. per 100 cc. by dialysis for six hours. If the artificial kidney is available, this certainly constitutes the procedure of choice for severe salicylate poisoning; it may be lifesaving in many such cases.—D. C. Schadt, M.D., Salicylate Intoxication in an Adult, *A. M. A. Archives of Internal Medicine*, August, 1958.

SOLITARY PLEURAL EFFUSION DUE TO MYXEDEMA

Samuel J. Schneierson, M.D.
and
Melvin Katz, M.D., Bronx, N. Y.

A patient who had complained of a mild, nonproductive nocturnal cough developed slight swelling of both legs and was then found on fluoroscopy to have a right-sided pleural effusion. Part of the fluid was removed by thoracentesis; the rest disappeared gradually after a diagnosis of myxedema was made and treatment with thyroid substance (in dosages up to 0.06 Gm. per day) was begun. The patient's appearance improved remarkably, and his cough stopped. The diagnosis was confirmed at autopsy when the patient died, half a year later, after a cerebral hemorrhage. This experience illustrates the fact, already known, that serous effusions sometimes occur in myxedema even in the absence of cardiovascular, renal, or other causes of water retention; but the case was impressive because in this patient the unilateral pleural effusion was the sole presenting effusion in the course of the myxedema.

Serous effusions are known to occur in untreated and inadequately treated myxedema even in the absence of cardiovascular, renal, or other causes of fluid retention. Most often the effusion is in the pericardium,[1] but there are instances on record in which ascites[2] and ascites with pleural effusion[3] appeared in the course of myxedema. The occurrence of a unilateral pleural effusion as the sole presenting effusion in the course of myxedema has not been reported to our knowledge.

Report of a Case

A 73-year-old man was admitted to the medical service of Lebanon Hospital on July 5, 1957, because of a right-sided pleural effusion detected on fluoroscopy during the course of examination by his physician four weeks before. For three months there was a relatively mild, nonproductive nocturnal cough. Four weeks prior to admission slight swelling of both legs and ankles was noted, more pronounced on the left side. This did not progress.

At the age of 15 years the patient had had acute cellulitis of the left lower extremity for which multiple incisions and drainage were required. At 67 years he had had a bilateral inguinal hernioplasty. He emigrated to the United States from Greece in 1915. Aside from a disclosure of heavy cigarette smoking during adult life up to the age of 53 years and moderate alcohol intake, response to further inquiry was not contributory.

Physical examination revealed a small, well-developed, and well-nourished man, ambulatory, who did not appear acutely or chronically ill. There was definite physical and mental slowness. There was no dyspnea, orthopnea, or cyanosis. His blood pressure was 170/90 mm. Hg and pulse rate 76 per minute and regular. The hair of his eyebrows and scalp was sparse and dry. The neck veins were not engorged, and the thyroid gland could not be palpated. Classic signs of a large right-sided pleural effusion were elicited. The heart was not detectably enlarged, and there was a regular sinus rhythm with rate of 76 per minute. The heart sounds were of good quality, with a grade-2 apical systolic murmur and the aortic second sound greater than the pulmonic second sound. There was no abdominal tenderness, nor was there evidence of palpable viscera, masses, or abdominal fluid. There were numerous scars on the left thigh and leg, bilateral varicose veins of the legs, and ankle edema, 2+ on the left and 1+ on the right.

The patient was regarded as having myxedema in addition to a right-sided pleural effusion of undetermined etiology. Studies were designed to include measures which might disclose the origin of the pleural effusion, as well as to corroborate the impression of myxedema and to delineate the latter as being either primary or secondary to hypopituitarism.

Laboratory Findings.—Laboratory determinations disclosed a hemoglobin level of 11.6 Gm. per 100 cc. and red blood cells, 3,700,000 per cubic millimeter, with 58% polymorphonuclear leukocytes, 28% lymphocytes, 8% monocytes, and 5% eosinophils. The urine specific gravity was 1.021, with albumin, 1+, sugar, none, and 10-12 leukocytes per high-power field. The sedimentation rate was 84 mm. per hour (Westergren). Fasting blood sugar level was 96 mg. per 100 cc., and urea nitrogen level was 21 mg. per 100 cc. Serum total protein level was 8.4 Gm. per 100 cc., with albumin 4.8 Gm. and globulin 3.6 Gm. per 100 cc. The total serum cholesterol level was 381 mg. per 100 cc., with esters, 219. Serum alkaline phosphatase level was 3.3 Shinowara (S.J.R.) units, and 24-hour urinary excretion of 17-ketosteroids was 10.5 mg. Cold hemagglutinins could not be detected in the serum. Sputum findings were negative for acid-fast bacilli and cytologically negative for tumor cells. Stool examination did not reveal parasites or ova. The electrocardiogram revealed flat T waves but was otherwise normal.

X-ray of the chest revealed a moderate-sized basal pleural effusion on the right, a small calcification in the left hilar region, elongation and tortuosity of the descending aorta, and minimal left ventricular enlargement. X-ray of the skull disclosed a normal sella turcica. The patient was not sufficiently cooperative for a valid determination of the basal metabolic rate.

On July 10, 1957, a thoracentesis was performed on the right side, with removal of 500 cc. of clear yellow fluid. No attempt was made to remove the entire effusion. X-ray of the chest immediately after the procedure revealed considerable residue of fluid. The aspirated fluid was negative for acid-fast and other bacteria on smear and culture, and cell block was negative for tumor cells. The patient refused consent for bronchoscopy. Venous pressure was 80 mm. H_2O, arm to tongue circulation time (Decholin) 35 seconds, and arm to lung time (ether) 10 seconds.

From the Department of Medicine and the Bertha C. Reiss Radioisotope Laboratory, Lebanon Hospital.

On July 12, 1957, tracer studies were initiated after oral administration of 39 μc of radioactive iodine (I^{131}). Thyroid uptake at five hours was 3.7% of the administered dose; at 24 hours the value was 5.8%. On July 24, 1957, similar studies were done after the intramuscular administration of three consecutive daily doses of 10 U.S.P. units of thyrotropin. The five-hour uptake was now 4.9% and the 24-hour uptake 6.0%, not significantly different from the initial tracer data.

Diagnosis.—The clinical diagnosis of myxedema was confirmed by the pertinent laboratory studies detailed above. Failure of thyroid uptake of radioactive iodine to rise significantly after administration of thyrotropic hormone indicated that the hypothyroidism was primary, although there are exceptions to this generalization.

None of the conventional etiological factors of pleural effusion was discovered in this case. There was no clinical evidence of congestive heart failure. In this connection it should be noted that prolongation of circulation time (as in this case) is characteristic of myxedema and corresponds closely with the decrease in basal metabolic rate.[4] No evidence of intrathoracic neoplasm or active pulmonary tuberculosis was found. Renal disease or other systemic causes of fluid retention could not be implicated. We therefore suspected that the pleural effusion in this instance was a direct result of myxedema without the intermediation of congestive heart failure, as in many instances pericardial effusion occurs in myxedema.[1c]

Therapy and Course of Disease.—No therapeutic regimen for fluid retention was instituted. The patient remained on a regular diet and was kept ambulatory. On July 26, 1957, he was discharged to the care of his referring physician with instructions to take ½ grain (0.03 Gm.) of thyroid daily. This dosage was to be cautiously increased after a short interval of observation. After three weeks the daily dose of thyroid was increased to 1 grain (0.06 Gm.) daily. There was remarkable improvement in the patient's appearance, and his physical and mental status improved strikingly. His cough disappeared, as did the physical signs of pleural effusion. On Sept. 5, 1957, x-ray of the chest disclosed clear lung fields with no evidence of pleural fluid. The daily administration of thyroid was continued.

The patient enjoyed good health until Jan. 30, 1958, when he collapsed in the bathroom of his home. Examination by his physician disclosed stupor and left-sided hemiplegia. His blood pressure was 110/80 mm. Hg and pulse rate 88 per minute and regular. After readmission to the hospital, the patient's general status deteriorated progressively in spite of supportive measures. Coma ensued, signs of bronchopneumonia appeared, and death occurred on Feb. 4, 1958.

Postmortem Findings.—The pituitary gland weighed 0.7 Gm. and was not remarkable. The thyroid gland weighed 6.3 Gm. and was very small; it had a grayish, pale tan color. On section, an increased amount of connective tissue was noted; no colloid could be seen grossly. Microscopic examination revealed marked increase in fibrous and fat tissue, dense infiltrations by lymphocytes, and almost total replacement of functioning parenchyma. Surviving acini were markedly distorted by Hürthle cell changes. There was no evidence of patterns of the Riedel type. The right and left adrenal glands weighed 6.5 and 6 Gm. respectively. They were triangular in shape and normal in size and position. The capsules were thin and translucent and the cortices yellow in color with a normal amount of lipid. The medullas were almost totally autolyzed.

There was severe tracheobronchitis. Extensive bronchopneumonia involved both lower lobes with focal areas of acute fibrinous pleuritis. The left ventricle was slightly hypertrophied. The aorta was atheromatous and partially calcified in its abdominal portion.

Examination of the brain disclosed asymmetry of the cerebral hemispheres, marked injection of the vessels on the surface of the hemispheres, and marked atherosclerosis of the vessels at the base. There were marked subarachnoid hemorrhages over both cerebellar hemispheres, a large hemorrhagic area in the right lateral ganglionic region, distention of the right cerebral ventricle with fresh clotted blood, and slight compression of the contralateral ventricle, which was filled with blood. A hemorrhagic area 4 cm. in diameter involved the right internal capsule and basal ganglions with compression of surrounding tissue. There was no evidence of neoplasm. Sections of the midbrain, cerebellum, and spinal cord revealed no abnormalities.

Comment

Myxedema is seldom considered as one of the many etiological possibilities in the diagnostic problem of unilateral pleural effusion. In a study of a large number of cases of pleural effusion in which a major objective was a survey of the causative factors, hypothyroidism was not recorded.[5] On the other hand, pericardial effusion in myxedema is well documented, even in the absence of congestive heart failure. Kern and co-workers [1c] emphasized the hitherto unrecognized frequency of pericardial effusion in myxedema in their study of four consecutive cases of myxedema, in each of which the presence of a considerable pericardial effusion was proved by aspiration. None of these patients had congestive heart failure, and none was found roentgenologically to have pericardial effusion. Two had relatively little enlargement of the cardiac silhouette.

Other authors have reported myxedema with ascites [2] and with ascites and pleural effusion.[3] In all of these documented instances of myxedema with serous effusions, consistent treatment with thyroid extract resulted in complete clearing of the entire syndrome. In our patient administration of thyroid extract was likewise followed by restoration of a euthyroid state and complete disappearance of the pleural effusion.

The pathogenesis of serous effusions in myxedema has been regarded as uncertain. Lange [6] appears to have demonstrated increased capillary permeability in five cases of myxedema, in all of which thyroid treatment caused rapid return of capillary permeability to normal. His method involved use of the dye, fluorescein, and a photoelectric skin colorimeter. With the same method there was no abnormal increase in capillary permeability in cardiac edema and in the edema of hepatic cirrhosis.

Conclusions

It is our suspicion that, among the many cases of pleural effusion in which the cause remains unknown even after intensive study, there may be some in which myxedema is etiological and unrecognized. We suggest that myxedema receive consideration in the differential diagnosis of pleural effusion.

84 Grand Concourse (51) (Dr. Schneierson).

EXTRA-ARTICULAR ARTHRODESIS OF THE SUBTALAR JOINT (GRICE PROCEDURE)

RESULTS IN SEVENTEEN PATIENTS WITH CEREBRAL PALSY

Lenox D. Baker, M.D.
and
Richard A. Dodelin, M.D., Durham, N. C.

The surgical immobilization of the subtalar joint, helpful in certain cases of poliomyelitis, has likewise been found helpful in occasional patients with cerebral palsy. If certain supplementary procedures are done to insure proper muscle balance, the subsequent growth of the foot in young patients should not be affected. The operation has been carried out on 29 feet in 17 patients, of whom 11 had not been walking. After the operation, 10 of the patients became free of both crutches and braces, and all but one, whose athetosis was so severe that he could not sit alone, became ambulatory.

This report is on the use of the Grice[1] extra-articular arthrodesis of the subtalar (subastragalar) joint in patients with cerebral palsy.

Grice has described the indications for and the results from the use of this orthopedic surgical procedure in patients with poliomyelitis. His two papers[2] on the subject describe in detail the operation and give emphatic warnings of complications. Our experiences in carrying out the operation have been the same as those reported by him.

During the past four years in four papers[3] on the use of surgery at Duke Hospital in the rehabilitation of patients from the North Carolina Cerebral Palsy Hospital, warnings were given on the importance of recognizing that the results from surgery in patients with cerebral palsy have not been and will not be as satisfactory nor as predictable as they are in patients with poliomyelitis. Nevertheless, if properly done, surgery offers a possibility of ambulation or of making a patient brace-free, neither the difficulty of decision nor the improbability of complete rehabilitation should hinder efforts at practical restoration of these functions. At the North Carolina Cerebral Palsy Hospital the philosophy is, "If you can, get them to walk, preferably brace-free." In following this program we do not hesitate to do an indicated operation. Experience has taught us that when surgery is indicated it should be done early. The training should be given after the opera-

---

From the North Carolina Cerebral Palsy Hospital and the Orthopaedic Division of the Department of Surgery, Duke University School of Medicine. Dr. Dodelin is an Orthopedic Fellow of the National Foundation for Infantile Paralysis.

Read before the Section on Orthopedic Surgery at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

tion. The program should not be training followed by operation. Surgery should no longer be looked on as a last resort. Braces should be the last resort and should be used only when surgery or other procedures cannot free a patient of encumbering, expensive, noisy, uncomfortable appliances. One of us (L.D.B.), in a previous paper based on 944 consecutive patients, reported only 164 (16.7%) who were considered suitable for operation. If these figures do not prove that this program has been nonradical they at least illustrate that surgery has been used rarely and only after the possible benefits of operation have been evaluated. The same conservative policy has been followed in the use of the Grice extra-articular arthrodesis of the subtalar joint in 29 feet in 17 patient.

In his original article Grice reported the operation as a procedure to be used in combination with necessary tendon transplants in patients who had had poliomyelitis with resulting paralysis of the anterior and posterior tibial muscles. In a second paper he reported the use of the operation in 52 such patients and mentioned 16 feet operated on in an attempt to correct severe pronation, some cases of which were associated with cerebral palsy. He did not include these 16 feet in his report nor did he break them down numerically into their respective categories. The present report, the first on the use of the procedure in patients with cerebral palsy, is made after conferences with the originator of the operation and with his permission.

Indication for Operation

The indications for stabilization of the subtalar joint in the patient with cerebral palsy are the same as in any other group of patients. As stated in previous publications, the rehabilitation of the patient with cerebral palsy, as in all patients with neuromuscular problems, depends on the restoration of muscle balance, the proper alignment of joints, the control of joint motion, and the establishment of correct posture with normal relationships in the line of gravity. The Grice procedure done in the properly selected patient in whom, insofar as possible, muscle imbalance has been corrected can contribute materially in this rehabilitation. Grice described the foot in which the operation is indicated as follows:

> Initially the deformity is similar in appearance to that of a mildly pronated foot. There is slight eversion of the heel, moderate prominence of the head of the astragalus (talus) medially, and abduction of the metatarsus. Unlike the pronated foot with good musculature, the paralytic valgus foot usually becomes progressively worse. It is difficult to prevent the development of this deformity by the use of supportive apparatus, such as arch supports, braces, or casts. There are several factors entering into the progressive character of this type of foot deformity. The deformity is initiated by muscle imbalance which displaces the tarsus in valgus and depresses the arch. The functional stress of walking increases the deformity. Inasmuch as these patients are in the actively growing period, the subsequent growth of the bones in the abnormal position increases and fixes the altered contour of the mid-tarsal structures. In a few years the foot may assume the appearance of a very flat foot.
>
> . . . the heel is displaced into eversion by the unopposed action of the peroneal muscles and the gastrocnemius. As the calcaneus is everted, its anterior portion is displaced laterally and posteriorly. As a consequence, there is loss of the normal support beneath the head of the astragalus which drops into equinus and projects further anteriorly. The backward displacement of the calcaneus and the forward movement of the astragalus results in abduction of the metatarsus.
>
> The surgical correction of this deformity is for the purpose of obtaining several major objectives. The calcaneus must be replaced beneath the astragalus and maintained in normal relation to it. The astragalus must be brought up out of equinus. Muscle balance should be restored by tendon transplantation to avoid recurrence. The deforming everting power of the peroneal muscles should be removed and active inversion and dorsiflexion should be restored to the astragaloscaphoid (talonavicular) area. Since it is desirable to correct this deformity in the young child before it has become fixed, the operative technique should not interfere with subsequent growth of the foot.

The indications for operation in patients with cerebral palsy and who have these deformities is in no way different from the indications in the patient who has had poliomyelitis except that in the poliomyelitic foot the deformity is a result of a flaccid paralysis of the tibial muscles, whereas in the cerebral palsied foot the deformity is a result of a spastic or tension paralysis of the peroneal and the triceps surae muscles. The indications for operation, namely, the reestablishment of balance, the correction of alignment, and the restoration of function, are the same in each group of patients.

Operation in Seventeen Patients

In accordance with these standards and objectives, the Grice extra-articular stabilization of the subastragalar joint was performed for the first time at Duke Hospital on Feb. 24, 1953, on a patient from the North Carolina Cerebral Palsy Hospital who had spastic quadriplegia. Between February, 1953, and June, 1956, the operation was carried out 29 times in 17 patients. Two feet were operated on in one patient, 3 years of age; 3 feet in two patients, 4 years of age; 2 feet in one patient, 6 years of age; 16 feet in nine patients, 8 to 9 years of age; 1 foot in one patient, 11 years of age; and 5 feet in three patients, 12 to 13 years of age. The average age was 8 years and 4 months. After we had observed the 16-month result of operation in the first patient, nine additional feet were operated on in 1954. Four of these patients were 9 years of age; two were 12; two were 8; and one was 13.

The results in these 11 feet warranted using the procedure in younger patients. In 1955 the operation was done bilaterally in a patient 3 years of age (fig. 1 and 2). Three feet were operated on in two patients 4 years of age. A three-year follow-up examination of these five feet demonstrated that the procedure had not interfered with growth and therefore can be carried out with safety in the young patient before fixed deformities develop.

In 16 of the 29 feet operated on, autogenous grafts were used. In the 13 feet in which homogenous grafts were used, 9 had rib strut-grafts; two had cortical strut-grafts from an ulna; two had cortical strut-grafts from skull-flaps. Because of the general trend toward the use of autogenous bone when available and in spite of the excellent results obtained in this group of patients in whom homogenous grafts were used, we now use autogenous bone in this procedure.

Types of Operative Procedures

The 29 operations were done by 10 different surgeons, 14 by one of us (L.D.B.), 1 by another senior staff member, and 14 by 8 different resident surgeons. All the end-results were evaluated by one of us (L.D.B.). Fifteen of the feet were involved with spastic paralysis only; 10 were involved with both spastic paralysis and tension athetosis; four were involved with tension athetosis only. In the 10 feet involved with mixed paralyses, in most instances the patient had a tension athetosis of a generalized nature plus spasticity in the lower extremities, with clonus, positive Babinski reflexes, hyperactive reflexes, and stretch reflexes. The time interval between operation and evaluation of results ranged from two to five years, with an average of three years and two months. The 17 patients reported have had a total of 121 surgical procedures. These operations were as follows: Grice procedure, 29; gastrocnemius aponeurosis lengthening, 25; Achilles tendon lengethening, 1; obturator neurectomy, 15; adductor tenotomy, 10; popliteal neurectomy, 5; recession of heads of gastrocnemius, 4; transplant of patella tendon, 3; transplant of a peroneal tendon, 2; transplant of the anterior tibial tendon, 1; retinaculum release at the knee, 1; posterior tibial tenotomy, 2; Intrapelvic obturator neurectomy, 2; osteotomy, 2; release of gluteus minimus (Durham procedure), 2; semitendinosus transplant to the patella, 2; Chambers subastragalar stabilization, 1; soleus neurectomy, 2; rectus femoris release, 4; release of fascia lata, 2; and release hamstring tendon, 6. These are the actual number of procedures performed; that is, a procedure done bilaterally was counted as two operations. Two procedures done through the same incision, such as an adductor longus lengthening and a neurectomy of the obturator nerve, were counted as two procedures.

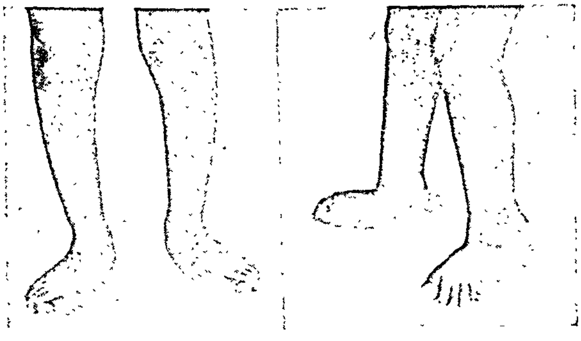

Fig. 1.—Feet of 3-year-old spastic quadriplegic child, illustrating typical equinovalgus deformities.

For the operations the 17 patients were taken to the operating room 36 times, an average of approximately two visits to the operating room per patient, with an average of 3.4 procedures per visit. It was not unusual for one of these patients to have the Grice procedure done bilaterally combined with bilateral adductor myotomy, bilateral obturator neurectomy, and bilateral gastrocnemius aponeurosis lengthening at one sitting, the multiprocedures being carried out by two operating teams. The average operating time for these multiprocedures has been one hour and 45 minutes.

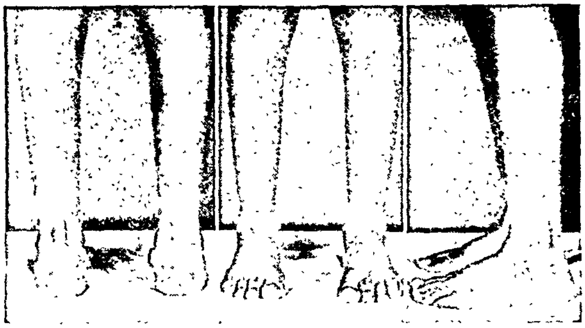

Fig. 2.—Feet of patient in figure 1 three years after lengthening of gastrocnemius aponeurosis and Grice's extra-articular subtalar stabilization.

Results

In the 29 feet operated on, the following complications, all of which were described by Grice, were encountered: 1. Due to poor placement of the grafts one of the feet had to be reoperated. Correction was carried out at the end of four weeks. The result was excellent. 2. Five feet were in too much varus. Two of the five deformities were due to overactive posterior tibial muscles. Tenotomy of the tendons of the involved muscles corrected the varus. The other three varus deformities are not sufficiently severe to warrant correction. One of these appears to be due to an overactive posterior tibial muscle. The patient is being kept under observation and, if necessary, the posterior tibial tendon can be released. In one patient one of the grafts penetrated the dorsal cortex of the astragalus. The protruding portion of the graft was absorbed. The end-result is good. In two feet, as indicated by roentgenograms, autogenous grafts appear to have been absorbed. Both feet are stable and are in anatomic alignment. Function is excellent. In one foot autogenous grafts appear, as shown by roentgenograms, to have failed to unite to the os calcis. The foot is stable, painless, and in normal alignment. Function is good.

Before therapy 11 of the 17 patients were nonambulatory. One was ambulatory with braces; one was ambulatory with a pushcart and braces. The five ambulatory patients, in addition to having cerebral palsy, had the awkward gait associated with talipes equinovalgus deformity.

Of the 17 patients only one is now considered as nonambulatory. However, he is able to get about with bilateral long leg braces, pelvic band, and a pushcart. His feet are in excellent alignment. Surgery in this patient consisted of several neurectomies and tenotomies done at the same time as the Grice procedure. This patient was severely athetoid before therapy and could not sit alone. One of the patients, because of an overactive posterior tibial muscle and mild varus of the foot, uses a short leg brace with an outside pullover strap. Eventually posterior tibial tenotomy may be needed. Ten of the 17 patients are free of both crutch and brace. One of these, because of poor balance, uses a cane. Evaluated on the basis of function and cosmetic appearance, the results in the 29 feet operated on have been good to excellent. Since therapy, 16 of the 17 patients are ambulatory.

CLINICAL NOTES

NARCOTIC WITHDRAWAL SYMPTOMS IN NEWBORN INFANTS

Ralph H. Kunstadter, M.D., Reuben I. Klein, M.D., Evelyn C. Lundeen, R.N., Winifred Witz, R.N.
and
Mary Morrison, R.N., Chicago

With the alarming increase in the use of narcotics among young adults, we are confronted with the serious problem of the care of infants born of mothers addicted to narcotics. Many of these infants are prematurely born [1] and the mortality rate is high.[2] These infants are particularly predisposed to asphyxia and anoxia and often have respiratory distress at birth or shortly thereafter. A high percentage of those who die show hyaline membrane disease and resorption atelectasis at autopsy. In addition to the more immediate serious effects of the narcotic on the infants during labor and shortly after birth, there may be symptoms and signs of narcotic withdrawal in those born of addicted mothers. These usually become manifest within hours after birth and, if unrecognized and untreated early, the infant may die.

The majority of the infants received in our premature station come from other hospitals and homes and are born of parents in the lower socioeconomic groups. Many of these mothers have had little or no prenatal care and often little information is available to us when the infant arrives in the hospital. Therefore, it becomes incumbent upon our nurses and physicians to be aware of this potential hazard and to be able to recognize and treat these infants who present in many instances a classic syndrome of narcotic withdrawal signs.

Because we believed that this syndrome was becoming increasingly important, a short chapter relating to the problem was incorporated in "The Care of the Premature Infant" [3] which had been in preparation since 1956 and was published in May, 1958. In a recent publication, Goodfriend, Shey, and Klein called attention to the syndrome of narcotic withdrawal in newborn infants and reviewed the literature.[4] Subsequently, articles have appeared in the literature by Cobrinik and his associates,[1] Schneck,[2] and Steg.[5] However, it is interesting that over 10 years ago Perlstein [6] called attention to congenital morphinism as a rare cause of convulsions in the newborn infants and described withdrawal symptoms in a full-term infant. We have been impressed, as have others, by the paucity of references to this problem in the literature in spite of the increase in narcotic addiction.

From the Premature Infant Station, Michael Reese Hospital.

Because of the serious nature of this problem, we believe that this report, encompassing our experience as well as that of other authors, should be widely circulated so that all physicians as well as nurses dedicated to the care of infants should be familiar with the syndrome and the management of the patient.

The table shows the more important data related to five infants, four premature and one full-term, observed by us during the past three years. The important symptoms and signs in their order of importance as observed by us and others are as follows: respiratory distress including rapid respirations, grunting, retractions, intermittent cyanosis, and periods of apnea; hyperactivity with trembling, twitching, or convulsions; shrill, high-pitched cry; sucking of hands and fingers as though constantly hungry; vomiting; diarrhea; hyperpyrexia; excessive weight loss; sneezing; diaphoresis; anorexia; yawning; and incomplete Moro reflex.

Data Concerning Narcotic Withdrawal Symptoms in Five Infants Born of Addicted Mothers

Case	Sex	Race	Mother's Age, Yr.	Birth Wt., Gm.	Drug Used	Probable Duration, Yr.	Dose(Mg.) and Time(Hr.) Prior to Delivery	Type of Delivery	Condition at Birth	Symptoms	Treatment	Recovery, Days	Remarks
1	M	N	32	1,610	Heroin	3	3.8;2-3	Spontaneous, cephalic	Active, crying, good color, Moro good; pupils normal, slight edema of eyelids	Slight periods of apnea and cyanosis; sucking good; frequent vomiting	Oxygen, 3 days	4	Discharged on 47th day; w 2,125 Gm., condition good
2	F	N	29	1,260	Heroin	1½	30;3	Precipitate	Poor; asphyxia and cyanosis; grunting respirations, shallow and rapid, retractions	At 14-16 hr., hyperactivity, trembling; shrill cry; rapid respirations; cyanosis; long periods of apnea; acts hungry constantly; sucks fists and fingers; intermittent severe tremors	Oxygen continuously; tincture of opium, 0.02 cc. q 4 hr.; penicillin and streptomycin	Died at 72 hr. with continuous withdrawal symptoms and respiratory distress	Postmortem; patent ductus arteriosus; coarctation of aorta; atelectasis; hyaline membrane
3	M	N	37	1,825	?	?	?	Spontaneous, cephalic	Good	Excessive vomiting first 48 hr.	Oxygen 48 hr.	2	Discharged on 44th day; wt 2,300 Gm., condition good
4	M	N	29	2,050	Heroin Morphine	?	?	Spontaneous, cephalic	Poor; hypertonic; inspiratory crow; loud, shrill cry	Third day appeared constantly hungry; sucking fists continuously; diarrhea. 6th day, hyperactive, tremors, temp. 106.2F; sucking constantly, 7th day temp. normal	Phenobarbital on 6th day; chloramphenicol, 50 mg. q 8 hr., 6th-8th day	7	Discharged on 34th day; wt 2,910 Gm., condition good
5	F	W	27	2,930	Heroin	14	?;1-2	Spontaneous, cephalic	Good; appeared normal	At 24 hrs., shrill cry, hyperactive; clonic convulsions. Phenobarbital 5 days with improvement. 24 hr. later, infant again hyperactive, trembling. Phenobarbital additional 5 days.	Phenobarbital 8-15 mg. q hr., 10 days	10	Discharged on 22nd day; wt. 2,930 Gm. condition good

Comment

The symptoms may appear shortly after birth or be delayed several hours or more, probably depending on the time relationship of the mother's most recent injection of narcotic and/or the dose to the time of birth. It has been stated that withdrawal symptoms do not occur unless the mother has taken the drug constantly, the last dose being administered less than a week prior to the birth of the baby. In our group we were able to confirm that three mothers were taking heroin intravenously; one, both heroin and morphine, and one we presumed was taking heroin but we had no verification. All were habitual users, and the known duration of addiction, as self-admitted, was 3, 1½, and 14 years respectively. The duration of addiction by the other two is unknown. As most addicts are prevaricators, any admissions may not be reliable In none of the five mothers were we able to trace the onset of addiction to the prolonged use of narcotics for the pain of disease or injury.

The syndrome of narcotic withdrawal in the newborn infant presents two significant signs that have been recorded by all observers: (1) hyperactivity, trembling, twitchings, or convulsions, and (2) shrill, high pitched, prolonged cry. For those unfamiliar with the syndrome and unaware of addiction by the mother, tetany, intracranial hemorrhage, meningitis, hypoglycemia, or other causes of convulsions may be suspected, and a great deal of time may be lost by performing unnecessary laboratory tests in an attempt to establish a diagnosis.

The almost constant sucking and chewing on the hands and fingers as if hungry are rather dramatic and, we believe, unique signs, particularly in the premature baby. Vomiting and diarrhea are frequent and may be the only signs in the absence of the more typical nervous system manifestations. Respiratory distress is frequent, appears early, and may be manifested by cyanosis and rapid grunting respirations with or without retractions. The latter is highly suggestive of hyaline membrane disease, particularly when associated with periods of apnea or rapid respiratory rate. Mortality is definitely related to the severity of respiratory distress, which in turn is partly dependent on the degree of intrauterine anoxia resulting from narcotization in utero. Case 2 in the table is an example. Gradual improvement of the respiratory distress usually signifies a good prognosis. Fever, particularly hyperpyrexia, has been described and may be significant particularly in the premature infant in whom fever is usually conspicuously absent or slight in the presence of infection. One of our infants, case 4 (see table), developed a temperature of 106.2 F (41.2 C) on the sixth day but it fell to normal within 24 hours. Although an antibiotic had been given for 48 hours, we do not believe that the infant had an infection. None of the other four infants in our group developed fever. Other withdrawal symptoms comparable to those found in adults and described by Schneck[2] were not present in any of our patients. He mentions yawning, nasal stuffiness, sneezing, and increased sweating.

In untreated cases, the various signs may persist for five or six days. The time for recovery in the four of our five infants ranged from 2 to 10 days. One was of particular interest since on discontinuing phenobarbital after five days of continuous administration there was a recurrence of symptoms 48 hours later. After an additional five days of phenobarbital therapy, there was no return of symptoms.

For the treatment of withdrawal symptoms it has been recommended that morphine, tincture of opium, or camphorated tincture of opium be used in diminishing doses over a period of several days consistent with disappearance of symptoms and signs. We believe that if sedatives are required barbiturates are effective and safer than opiates. Two of our patients received no sedation, two received phenobarbital, and one tincture of opium. Recently Murray[7] treated five infants with methadone in doses of 0.5 to 1 mg. administered every 4 to 12 hours and continued in decreasing doses for several days or weeks. Tranquilizers, chlorpromazine (Thorazine) and resperine, have been found effective.[2] Three of our infants received oxygen, one continuously up to the time of death at 72 hours (case 2), and the other two for 72 and 48 hours respectively (cases 1 and 3). In the presence of respiratory distress, appropriate antibiotics should be used, as pneumonia is a likely complication. Feedings should be withheld until vomiting has ceased and the danger of aspiration has passed. Intravenously administered fluids may be necessary during the first 48 to 72 hours and possibly longer.

Summary

The increase in incidence of narcotic addiction among adults during the past few years has resulted in a rise in the number of infants born of addicted mothers. A large percentage of these infants are prematurely born, and both morbidity and mortality rates are high. Withdrawal symptoms frequently appear shortly after to several hours after birth. Recovery usually occurs if the infants do not die from early respiratory distress and if withdrawal symptoms are recognized early and adequately treated.

Five infants, four premature and one full-term, born of mothers addicted to narcotics during the past three years revealed withdrawal symptoms. Hyperactivity, trembling, twitchings, or convulsions; shrill, high-pitched, prolonged cry; and the appearance of being constantly "hungry" with sucking of the hands and fingers are particularly significant symptoms and signs.

Proper treatment consists of the administration of sedatives, preferably diminishing doses of barbiturates, oxygen and antibiotics for respiratory distress, and fluid and electrolytes parenterally when indicated in the presence of vomiting, diarrhea, and/or dehydration.

Oleandomycin Phosphate.—The phosphate salt of an antibiotic substance elaborated by species of Streptomyces antibioticus.—The compound has an empirical formula of $C_{35}H_{61}NO_{12}.H_3PO_4$, but its precise chemical structure has not as yet been determined.

Actions and Uses.—Oleandomycin phosphate exhibits antimicrobial activity in vitro against gram-positive organisms, being most active against staphylococci, streptococci, and pneumococci. It likewise inhibits the in vitro growth of a few gram-negative bacteria, notably Hemophilus influenzae, gonococci, and meningococci. Oleandomycin has negligible activity against coliform bacteria and other gram-negative organisms of the enteric group.

Oleandomycin phosphate is useful for the treatment of certain infections due to gram-positive coccal organisms such as Staphylococcus pyogenes var. aureus, beta-hemolytic streptococci, and pneumococci. However, in beta-hemolytic streptococcic or pneumococcic infections, penicillin or the tetracyclines are usually considered to be the agents of choice. In regard to Staph. pyogenes var. aureus, there is in vitro and clinical evidence to show that oleandomycin is active against strains of this organism, including some that are resistant to other commonly employed antibiotics. Thus, the drug has been employed successfully for the treatment of a variety of the milder and more severe staphylococcic infections, especially those refractory to erythromycin, penicillin, streptomycin, and the tetracyclines.

On the basis of both in vitro susceptibility tests and clinical experience, the actions and uses of oleandomycin appear to be quite similar to those of erythromycin. In general, both antibiotics are employed for the same type of infections and are subject to similar limitations in spectrum and effectiveness. There is some evidence to indicate the usefulness of oleandomycin against such gram-positive organisms as alpha-hemolytic streptococci and nonhemolytic streptococci. It has also been used in infections caused by such gram-negative organisms as meningococci, gonococci, or H. influenzae, but, except for gonorrheal infections, the evidence is inadequate to substantiate such use. Some evidence of in vitro activity against certain viruses, rickettsias, and protozoa has been presented; however, there is insufficient clinical evidence to substantiate its effectiveness against such micro-organisms.

On the basis of present knowledge, prolonged therapy with oleandomycin can produce oleandomycin-resistant strains of staphylococci. Staphylococcic cross resistance between oleandomycin and erythromycin can occur in some freshly isolated strains, although most erythromycin-susceptible strains are susceptible to oleandomycin. Complete cross resistance between oleandomycin and erythromycin, carbomycin, and spiramycin can be rapidly and regularly developed in vitro. Accordingly, as with any antibiotic, accurate bacteriological identification of the infecting organism and susceptibility tests are indicated before initiating therapy. When indicated, oleandomycin should be administered in sufficiently large amounts to control the infection before resistance can develop, and susceptibility tests should be repeated to insure that the organisms remain susceptible to its action. The valuable antistaphylococcic properties of oleandomycin can best be preserved by preventing its indiscriminate use.

The toxicity of oleandomycin seems to be low. Side-effects reported thus far have been limited to occasional reactions of cutaneous hypersensitivity, loose stools, and, rarely, diarrhea. The possibility of overgrowth of nonsusceptible organisms (notably Candida) exists but is considered to be much less likely than when the broader spectrum antibiotics are used.

Dosage.—Oleandomycin phosphate is administered orally, intravenously, and, occasionally, intramuscularly. The oral dosage for adults ranges from 250 to 500 mg. four times daily, the amount administered depending on the type and severity of the infection. The suggested dosage for children is approximately 30 mg. per kilogram of body weight per day given in divided doses.

For intravenous use, a sterile dry powder of the drug is diluted with either sterile water for injection, isotonic sodium chloride for parenteral use, or sterile 5% dextrose solution to make at least 250 cc. of solution not to exceed 2 mg. per cubic centimeter. This diluted solution is then infused slowly at a rate not to exceed 20 mg. (10 cc.) per minute. In the average adult, 1 to 2 Gm. daily, administered in divided doses every 6 to 12 hours, should be sufficient for most acute infections. In severe and fulminating infections, a daily maximum of 3 Gm. may be utilized in adults. In infants and children, the usual intravenous dose is 40 mg. per kilogram of body weight daily. Care should be taken to avoid extravasation of the drug into adjacent soft tissues. Oral therapy should be substituted for intravenous infusion as soon as feasible.

In occasional instances in which neither oral nor intravenous therapy is feasible, oleandomycin phosphate may be administered by intramuscular injection. Since the drug is irritating to the tissues by this route, it should be mixed with a local anesthetic prior to injection. For such use, 7.5 cc. of a 1 to 2% solution of procaine hydrochloride is added to 500 mg. of the dry, sterile powder of oleandomycin phosphate, so that each 1.5 cc. of the resulting solution will contain 100 mg. of the antibiotic. The usual intramuscular dose for adults is 200 mg. every six to eight hours by deep intragluteal injection, alternating sites and buttocks being used. Dosage for infants and children is reduced according to age, weight, and severity of infection. Extreme care should be taken to avoid injecting the solution containing procaine into a vein. Likewise, this solution should not be injected subcutaneously or into the fat layer; inadvertent injection into these tissues may cause pain and induration. Intramuscular therapy should be discontinued as soon as medication by the oral route is feasible.

Preparations: capsules 250 mg.; powder (injection) 500 mg.

Applicable commercial names: Matromycin, Oleandomycin Phosphate.

Pfizer Laboratories, Division of Chas. Pfizer & Co., Inc., and Wyeth Laboratories, Division of American Home Products Corporation, cooperated by furnishing scientific data to aid in the evaluation of oleandomycin phosphate.

Triacetyloleandomycin.—The triacetyl ester of an antibiotic elaborated by species of Streptomyces antibioticus.—The compound has an empirical formula of $C_{41}H_{67}NO_{15}$, but its chemical structure has not been determined.

Actions and Uses.—Triacetyloleandomycin has the same actions and uses as oleandomycin phosphate. After oral administration, the triacetyl ester is more rapidly and completely absorbed from the gastrointestinal tract than is the same amount of the phosphate salt. Hence, it produces higher blood levels, and fewer or less frequent doses may be used.

Dosage.—Triacetyloleandomycin is administered orally. Dosage is the same as that for oleandomycin phosphate.

Preparations: capsules 125 mg. and 250 mg.; suspension (oral) 25 mg. per cc.

Applicable commercial name: Cyclamycin.

Wyeth Laboratories, Division of American Home Products Corporation, cooperated by furnishing scientific data to aid in the evaluation of triacetyloleandomycin.

CHEMICAL LABORATORY

The Chemical Laboratory has authorized publication of the following statement.

WALTER WOLMAN, Ph.D., *Director.*

Monographs of tests and assays for new and nonofficial drugs adopted by the Chemical Laboratory of the American Medical Association represent an expression of opinion as to what might constitute adequate tests and assays to serve as a reference guide to those interested in the identity and quality of a new and nonofficial drug.

Completed monographs are published in the journal *Drug Standards* for those interested in the details of the procedures. Monographs on the following drugs have appeared in the July-August, 1958, issue of that journal. The cooperation of the listed pharmaceutical firms that furnished samples and data is acknowledged.

Aminopentamide sulfate.............(Bristol Laboratories, Inc.)
Decamethonium bromide..(Burroughs Wellcome & Co., Inc.)
Phensuximide..(Parke, Davis & Co.)

DIAGNOSTIC PROBLEMS

HEMOLYTIC AND HYPOCHROMIC ANEMIA AND ELEVATED COLD AGGLUTININ TITER IN A SEVEN-YEAR-OLD CHILD

Clinical Pathological Conference PM (423-57), Dec. 20, 1957, from the Department of Pathology and the Hektoen Institute for Medical Research of Cook County Hospital, Chicago, presented for publication by Daniel S. Kushner, M.D., and Paul B. Szanto, M.D.

Clinical Data

A 7-year-old Negro boy was admitted to the Children's Division of Cook County Hospital on Sept. 25, 1956, because of cramping, migratory abdominal pain of one week's duration. He had had no anorexia, vomiting, constipation, diarrhea, bloody or tarry stools, joint pains, or jaundice. He had no known contact with lead, insecticides, or rat poison. He was receiving no medication. He had always been a poor eater, preferring sweets to meat or vegetables. He was the eighth of nine children in his family. The pregnancy and delivery were normal, and his birth weight was 6 lb. (2,721.55 Gm.). He sat up at 5 months, walked at 12 months, and talked at 18 months. He had received triple toxoid, smallpox vaccination, and Salk vaccine. His only childhood disease had been mumps. The family history was negative for chronic diseases. A younger sibling had died of unknown causes in infancy. The parents and seven siblings are living and well.

Examination disclosed a small, alert, and cooperative boy in no distress but with striking pallor. His pulse was 80 per minute, respiration 18, temperature 99.6 F (37.6 C), and blood pressure 118/50 mm. Hg. His conjunctivas and scleras were pearly white. A few small discrete nontender posterior cervical lymph nodes were palpated. His cardiac apex beat was palpated in the fifth interspace in the midclavicular line. The abdomen was soft and flat. The liver edge was palpable one fingerbreadth below his right costal margin. A firm spleen tip was palpated one to two fingerbreadths below his left costal margin. His hemoglobin level was 3.6 Gm. per 100 ml.; the erythrocyte count was 2,490,000 per cubic millimeter and leukocyte count 12,800 per cubic millimeter, with a differential count of 67% polymorphonuclear leukocytes, 7% band forms, 1% eosinophils, 4% basophils, 16% lymphocytes, and 5% monocytes. Sickle cell preparations were negative on three occasions. His platelet count was 260,000 per cubic milimeter. Hemoglobin electrophoresis revealed an AA pattern; the fetal hemoglobin level was 1.8%. Urinalysis was negative, including tests for coproporphyrins. His blood cholesterol level was 210 mg. per 100 ml., total serum protein level 7 Gm. per 100 ml., serum calcium level 5.3 mg. per 100 ml., and indirect serum bilirubin level 2.1 mg. per 100 ml. His alkaline phosphatase level was 2.1 Bodansky units, and the icterus index was 10 units. A roentgenogram of his chest revealed normal heart and lungs. An aspiration biopsy of the sternal marrow was performed.

The patient was given three blood transfusions, after which all signs and symptoms disappeared, and he was discharged on Oct. 16 in excellent condition. He was readmitted on Feb. 12, 1957, with a history of fatigue, listlessness, lethargy, generalized weakness, and shortness of breath of two days' duration. Examination revealed an extremely pale, acutely ill child with white mucous membranes, pale tongue, and extremely pale palms and soles. He was lethargic and very weak. His pulse was rapid and regular; respirations were rapid and shallow. He was apprehensive. His spleen and liver were not palpable. Initial and subsequent blood cell counts are shown in the table. Hemoglobin electrophoresis again revealed an AA pattern, with a 1.1% fetal hemoglobin level; his mother's pattern was also AA; a Coombs' test was negative. Cold agglutinins were positive at a titer of 1:64 on Feb. 15. The nonprotein nitrogen level was 32 mg. per 100 ml. A tuberculin skin test was negative. Urinalysis was negative on repeated occasions, except for a trace of urobilinogen on Feb. 15, when the icterus index was 18 units; cephalin flocculation was negative, thymol turbidity 1.8 units, and gamma globulin 0.79 Gm. per 100 ml. A roentgenogram of his chest on Feb. 12 disclosed increased haziness in both lung fields, suggesting bilateral pneumonitis. On Feb. 20, direct and indirect Coombs' tests were negative; cold agglutinins were positive, 1:128, and cold hemolysin 1:4. It was technically impossible to type his blood. A needle biopsy of his sternal marrow was again performed.

He was given 300 cc. of type O–Rh negative blood on each of two successive days. He had low-grade fever and coughed frequently. The tip of his spleen became palpable. Fine rales were heard

---

Dr. Kushner is Associate Director of Medical Education, Cook County Hospital, and Instructor in Medicine, Northwestern University Medical School; Dr. Szanto is Director, Department of Pathology, Cook County Hospital, and Professor of Pathology, Chicago Medical School.

Dr. Sanford is Chief of Staff, Children's Division, Cook County Hospital, and Chairman, Department of Pediatrics, University of Illinois, College of Medicine.

throughout his chest. Penicillin and tetracycline were given for 11 days. On Feb. 19, he received 4 cc. of gamma globulin. On Feb. 25, he was afebrile, ambulatory, and asymptomatic, and all physical signs had regressed, but his erythrocyte count continued to be low (1,800,000 per cubic millimeter), and on March 15 cortisone therapy was instituted in dosage of 225 mg. daily for 14 days. On March 22, he developed low-grade fever without apparent cause, which abated after penicillin therapy, and his condition was again considered good. On March 27, he had a sudden hematemesis and lost 50 cc. of blood; 40 minutes later he had a massive upper gastrointestinal tract hemorrhage. His blood pressure was 110/0 mm. Hg. He was cold, clammy, pale, and gasping for breath. Ten minutes later, he had another massive hemorrhage of bright red blood from the nose and mouth, and he died.

Clinical Discussion

Dr. Heyworth Sanford: The problem concerns a 7-year-old boy who was admitted because of abdominal pain. From a clinical standpoint, abdominal pain is the second most common symptom for which children over a year old are examined by the pediatrician. Anorexia is the most frequent cause. Knowledge of the character of his pain was not helpful, and it was not associated with other gastrointestinal symptoms or with accidental or therapeutic ingestion of toxic agents.

The objective finding of significance was severe anemia, obviously raising the consideration of sickle cell anemia as a cause for the abdominal pain. The cardiac murmur, cervical lymphadenopathy, and hepatosplenomegaly are entirely consistent with a diagnosis of sickle cell anemia; but, to the amazement of the staff, the laboratory data failed to confirm the presumption of sickle cell anemia. The anemia was severely hypochromic, with a color index just under 0.5. Moreover, he had a polynucleosis. This is a far cry from the blood findings one would expect in a hemolytic anemia. The sickle cell preparations were repeatedly negative, and we find a normal hemoglobin electrophoresis, excluding any possibility of sickle cell disease. Nevertheless, the slightly increased indirect bilirubin level and the subsequent observation of increased urobilinogen are suggestive of a mild hemolytic process. In the course of the diagnostic efforts, the child was treated with blood transfusions; he improved and, since nothing more could be found, was discharged in satisfactory condition.

On the second admission four months later, he was much more severely ill, with manifestations of profound anemia. The difficulties encountered in typing his blood are of special interest and may have been caused by (1) the low red blood cell count, (2) interference by cold agglutinins, and (3) the presence of some basic disease process which directly caused the difficulty. Nevertheless, he was given a transfusion and improved until he developed a pneumonitis. This apparently responded to treatment, but the anemia increased, perhaps as a result of the infection.

There seem to be two clues to the diagnosis here. The first is the blood examination which revealed a hypochromic anemia with a leukocytosis consisting of numbers of polymorphonuclear leukocytes. More importantly, the reticulocyte counts ranged from 14 to 24%. That means that the body was doing its best to regenerate blood, rapidly throwing new forms out into the blood stream. A reticulocytosis like this may be the result of (1) regeneration after hemorrhage, (2) regeneration related to hemolytic anemia, and (3) a deficiency anemia.

The second lead concerns the cold agglutinins, whose presence was suggested by the blood typing difficulties, and which, in fact, were increased to a titer as high as 1:128. We find cold agglutinins in the following conditions: hemolytic anemia; certain infections, such as infectious mononucleosis or virus pneumonia; liver disturbances; and plasma cell (multiple) myeloma. The cold hemolysin, which was also described, is usually associated with paroxysmal hemoglobinuria, but this boy did not have hemoglobin in his urine. To return to the problem of anemia, the various causes of acute blood loss must be considered, such as result from injury, accident, operation, bleeding from esophageal varices, and duodenal or gastric ulcers; but there is nothing here to suggest acute hemorrhage, and the low color index means chronic blood loss with the development of iron deficiency. Reticulocytosis frequently occurs after gastrointestinal bleeding from Meckel's diverticulum, intestinal polyps, or telangiectases in ulcerative colitis and chronic intussusception. Those are all unlikely in this situation. Diagnoses of diseases in the dyshematopoietic group are rather well excluded by the absence of significant disturbance in the leukocytes or platelets and by what we must assume were two negative aspiration biopsies of the bone marrow.

With regard to tumors, neuroblastoma is a common enough condition and does produce abdominal pain and anemia; but this child had no signs of abdominal tumor, or peripheral evidences of bone marrow replacement, in the form of leukopenia or thrombocytopenia. For similar reasons, the diagnoses of lymphoma and leukemia can be excluded. With regard to the hemolytic anemias, a diagnosis of congenital hemolytic anemia can be dismissed because of the absence of jaundice. Sickle cell anemia can also be excluded. The acquired hemolytic anemias may result from poisons, circulating hemolysins, or other antibodies. The cold agglutinins, perhaps in relation to a virus pneumonia, could have caused the hemolysis.

This would leave unexplained the terminal gastrointestinal hemorrhage. Is there any condition, which is not an infection, which will produce a pseudohemolytic condition, or is there any kind of bleeding where the blood is trapped and suddenly hemorrhage appears? Blood trapping and infection occur, for example, in trypanosomiasis, with manifestations of pallor, anemia, and splenomegaly; but the tsetse fly does not exist in this climate. Is there any other place where the patient could have had blood trapped?

A rare condition associated with the trapping of blood is known as idiopathic pulmonary hemosiderosis. In this condition, there is a decrease in elastic fibers so that the pulmonary tissues do not expand; this leads to stasis of blood in the pulmonary capillaries, hemosiderosis, and bleeding into the lung. The condition occurs in young children and is accompanied by an atypical hemolytic anemia, that is, anemia with a slight increase in indirect-reacting serum bilirubin level and a slight urobilinogenuria.

The final hemorrhage would still demand explanation. There was no evidence of cirrhosis or marked splenomegaly to support a diagnosis of chronic congestive splenomegaly with bleeding from esophageal varices. The child may have had two independent conditions, such as hemolytic anemia, on whatever basis, and ulceration into the pulmonary vessels from tuberculosis; but there was no tuberculous infiltration shown in the chest film, and the tuberculin test was negative. The child was given cortisone, which was indicated for the hemolytic anemia; but this does aggravate gastric and duodenal ulcers. We could postulate hemorrhage from a previously silent peptic ulcer under the influence of the steroid therapy. I would still diagnose hemolytic anemia related to idiopathic pulmonary hemosiderosis or perhaps to an infectious process. I would like to hear the diagnoses of the medical students. (The medical students' diagnoses submitted were aleukemic leukemia, hemolytic anemia, histoplasmosis, normocytic metabolic anemia or macrocytic anemia of pernicious anemia type [nutritional or metabolic] due to sprue.)

Dr. Aaron Grossman: In view of the active hemolytic process, would a splenectomy have been advisable?

Dr. Sanford: If antibodies are being formed by the reticuloendothelial system, we first try to block them by using cortisone. If this fails, the next step is splenectomy. In this case the boy had no splenectomy, because he was improving on cortison therapy.

Dr. Paul B. Szanto: An aspiration biopsy [illegible] sternal bone marrow was performed. I sho[illegible] to ask Dr. Sanford to comment on the sli[illegible]

Dr. Sanford: Some megaloblasts and [illegible] normoblasts are present, as evidenc[illegible] erythropoietic activity.

Clinical Diagnosis.—The clinical d[illegible] hemolytic anemia, due to idiopathic pulm[illegible] mosiderosis, and terminal steroid-induced b[illegible] peptic ulcer.

Pathologist's Report

Dr. Szanto: The body was that of an underdeveloped, moderately emaciated boy. The pleural and peritoneal cavities were free of fluid and adhesions. There were no varices in the esophagus or gastric cardia. The stomach contained 40 cc. of mucoid, blood-tinged fluid. Neither the stomach nor the small or large intestine revealed any lesion. No source of the gastrointestinal hemorrhage was found. The liver was moderately enlarged (1,000 Gm.), firm, and pale tan. On cut section, the lobular pattern was distinct. Microscopically, moderate fatty changes and extramedullary foci of erythropoiesis were seen.

The kidneys were grossly and microscopically normal, except for pallor, especially of the renal pyramids. The spleen was moderately enlarged (100 Gm.) and firm. Microscopically, there was proliferation of the reticulum cells in the red pulp, as commonly seen after hemorrhage. The bronchopulmonary lymph nodes were moderately enlarged and showed similar reticulum-cell proliferation. The bone marrow showed the changes seen in the biopsy specimen, namely, evidence of increa[illegible] erythropoietic activity, with numerous normoblasts and some megaloblasts. Turnbull's reaction for iron deposit in the bone marrow was negative. The heart (160 Gm.) was of normal size and configuration. There was no evidence of rheumatic heart disease or any type of myocarditis.

The lungs were heavier than normal (850 Gm.) and had a peculiar rusty-brown color and firm nodular consistency, reminiscent of that seen in passive congestion secondary to mitral stenosis. We must emphasize, however, that this patient did not have mitral stenosis. This rusty-brown color and indistinctly nodular appearance, in the absence of mitral stenosis, is practically diagnostic for idiopathic pulmonary hemosiderosis, if some rare type of pneumoconiosis (siderosis of the lungs) is excluded.

Numerous large sections taken from the various segments of the lungs showed a uniform type of lesion. The alveoli contained numerous macrophages loaded with coarse brown pigment (fig. 1 and 2), which gave a positive iron reaction as hemosiderosis does (fig. 3). Some of the alveolar septums were thickened and quite cellular. Bronchioles and bronchi failed to reveal pathological changes. Special stains revealed interruption or even complete absence of elastic fibers in the alveolar septums. Occasionally, these fibers appeared thickened, frayed, or aggregated (fig. 4). The elastic fibers in the vascular walls were impregnated with iron. These histological findings fulfill the criteria for the diagnosis of idiopathic pulmonary hemosiderosis.

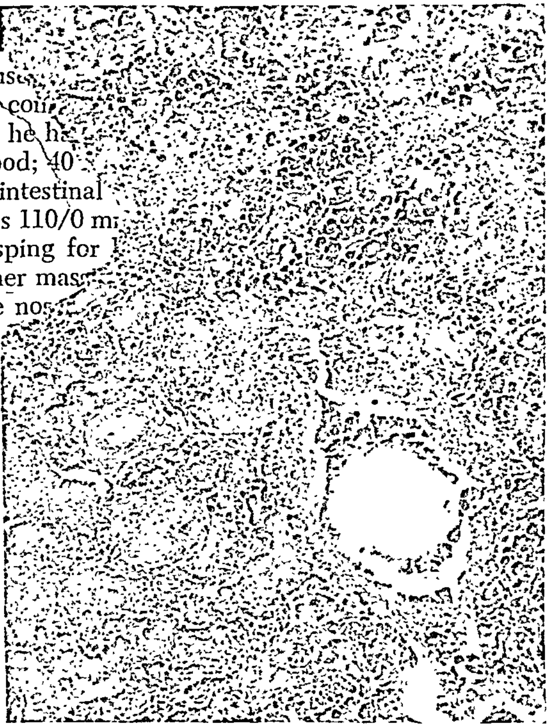

Fig. 1.—Numerous hemosiderin-containing macrophages in alveoli.

Pathological Diagnosis.— The pathological diagnosis was idiopathic pulmonary hemosiderosis, bilateral; bronchopulmonary lymphadenitis; and moderate splenomegaly (reactive chronic splenitis).

Comment

Dr. Szanto: The gross and microscopic findings in the lungs fulfill the criteria set for idiopathic pulmonary hemosiderosis or essential brown induration of the lungs. The hemoptysis and the pulmonary symptomatology (cough, chest pain, dyspnea, cyanosis, and expectoration) in this case were not prominent. Hemoptysis, which may be profuse and recurrent, is not always obvious because, just as was the case with this patient, the blood may be swallowed. Then, the pulmonary bleeding manifests itself either by the presence of occult blood in the stool or by hematemesis.

This rare disease, known since 1931, after the classic description by Ceelen [1] (although it was also described by Virchow [2]), usually occurs in childhood. A few cases affecting adults have been reported.[3] Some have been diagnosed by lung biopsy.[4] The subject may be of either sex and is often underweight for his age. Clubbing of the fingers may be present and may regress during spontaneous remissions.[5]

Apart from the obvious respiratory distress, which may require oxygen therapy, the most striking feature is anemia (pulmonary hemosiderotic anemia), which, though often profound, responds well to blood transfusions. Frequently, this anemia presents features suggestive of hemolysis, reflected in reticulocytosis, elevated serum (indirect) bilirubin level, moderately increased urobilinogen level, and in some patients mild jaundice. Red blood cell fragility is within normal limits. The anemia is hypochromic, microcytic, or normocytic. Leukocytosis may be present. Platelet counts and bleeding and clotting times are normal, but the cold agglutinin titer is frequently elevated, just as in this case.[5]

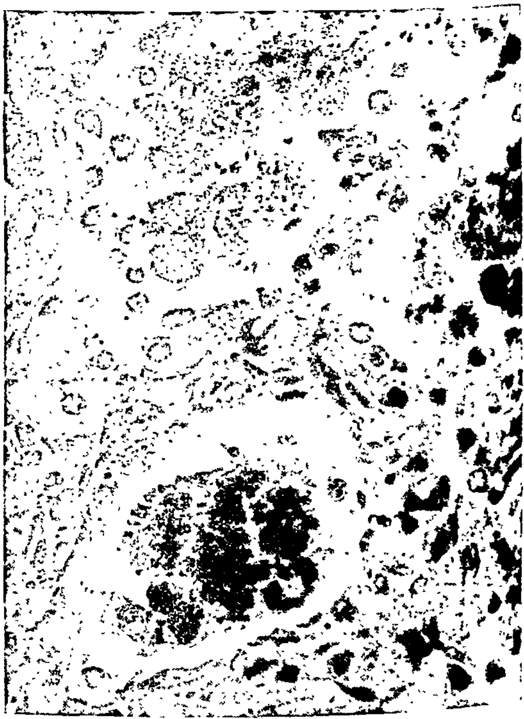

Fig. 2.—Hemosiderin-containing macrophages in alveoli (same as in figure 1 but with higher magnification).

The severe anemia associated with this disorder cannot always be explained by hemorrhage into the lung alone. Severe anemia has been observed in instances where no significant radiologic abnormality in the lung fields was present. Sputum, when present, contains numerous hemosiderin-laden macrophages (heart failure cells). Episodes of microcytic, hypochromic, iron-deficiency anemia of unknown cause associated with pulmonary infiltration, should lead to consideration of the possibility of this disease,[6] which is usually fatal a few years after the first attack.

Pathologically, the lungs in the previously reported cases grossly had the typical appearance of brown induration. Histological changes were characterized by diffuse intra-alveolar hemorrhages, leading to diffuse and nodular siderophagia, with heart failure cells, and fibrous thickening of the alveolar septums, complicated in some instances by the development of smooth muscle fibers,[1] and cuboidal metaplasia of the alveolar lining cells. In some instances, long-standing pulmonary hemosiderosis has led to pulmonary fibrosis, resulting in cor pulmonale. Nodular fibrosis resembling a miliary type of lesion may be present radiologically and pathologically.

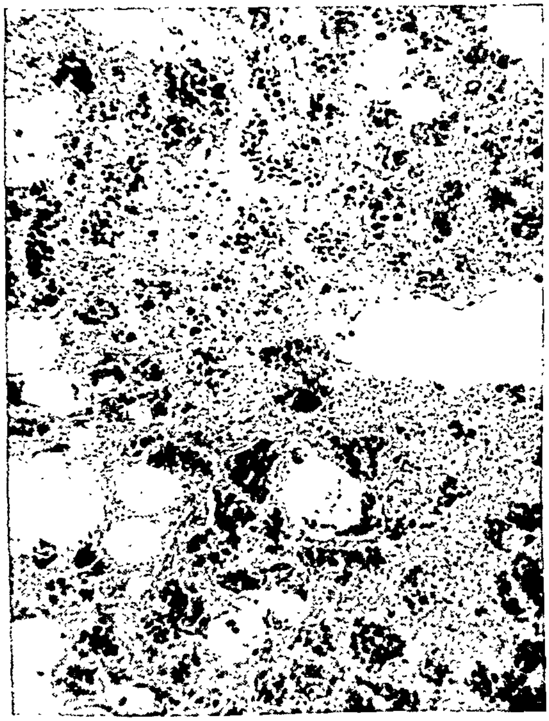

Fig. 3.—Hemosiderin identified histochemically by Prussian blue reaction (Turnbull's stain).

An interesting feature of this peculiar disease is the alteration of the elastic framework of the lung. The septal and vascular elastic tissue in most cases has shown degenerative changes, elastic fibers being frayed, fragmented, condensed, or completely absent. Foreign body giant cells may surround the degenerated elastic fibers.[5]

While the pulmonary alterations dominate the pathological findings in this disease, the spleen may be moderately enlarged, presenting follicular hyperplasia or a reactive splenitis; the regional bronchopulmonary lymph nodes may contain numerous hemosiderin-laden macrophages; and the bone marrow shows increased erythropoietic activity, secondary to severe blood loss.

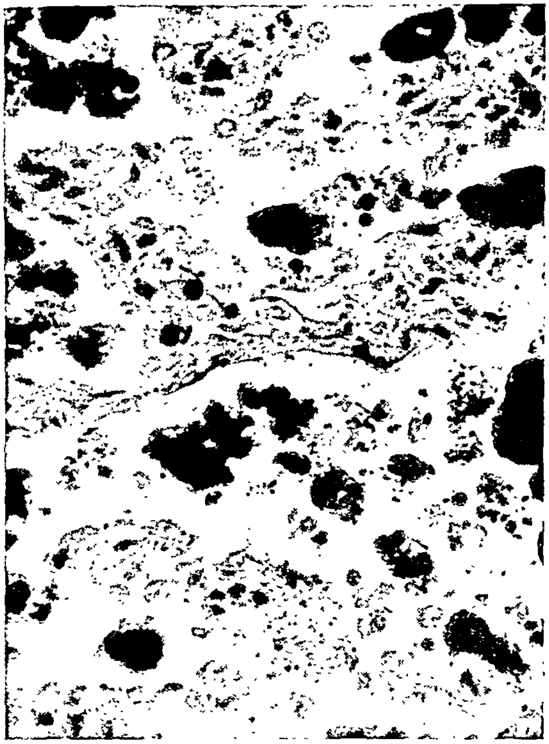

Fig. 4.—Elastic fibers absent in some areas, in others aggregated or frayed.

The cause of death varies. Acute suffocation and right heart failure cause death in many instances. Anemia is usually not the cause of death, although in this case pulmonary hemorrhage and shock superimposed on a severe chronic anemia accounted for the death.

The cause of the disease is unknown. It would be attractive to assume that the primary lesion is a congenital or acquired damage of the septal and vascular elastic tissue of the lung inflicted by an unknown agent. The morphologic alteration of the elastic tissue increases fragility of the pulmonary vasculature and causes the pulmonary hemorrhage[7]; however, in a few reported patients, who presented the typical clinical findings, death occurred at a stage of the disease when the elastic tissue of the lungs was intact. Therefore, it must be assumed that the alteration of the elastic tissue develops in a later stage of the disease. Another etiological consideration of potential therapeutic significance is that of Steiner, who diagnosed pulmonary hemosiderosis in a boy on the basis of lung biopsy. His patient responded well to splenectomy. On that basis, the author[8] assumed that pulmonary hemosiderosis is an immunoallergic condition, whereby the lung is the shock organ. Therapeutic response to corticotropin and cortisone also has been reported in this disease.[3]

Because of the alteration of the elastic tissue, idiopathic pulmonary hemosiderosis appears to be related to pulmonary elastic disease (or endogenous pneumoconiosis), a rare condition described by Walford and Kaplan.[9] This clinicopathological entity occurs in adults, usually in middle-age, and is characterized by a progressive clinical course, with pulmonary symptoms and cor pulmonale. Microscopically, the vascular and interstitial elastic tissue shows severe degenerative changes, without evidence of severe pulmonary hemosiderosis. While the clinical course in the latter condition is episodic, in pulmonary elastic disease it is persistent and progressive. Furthermore, the elastic tissue changes are not associated with hemosiderosis, or the hemosiderosis is very much in the background. On that basis, a separation of these two clinicopathological entities should be retained.

Normal Laboratory Values for Tests Cited in Text

Hemoglobin paper electrophoresis normally shows an AA pattern, demonstrated by the rapid migration of a single hemoglobin component. The absence of other abnormal hemoglobins such as S, C, and F negates a possible hemoglobinopathy as causing the hemolytic disease.

Fetal hemoglobin level is usually 1.3 to 2.0 Gm.%. An elevated level is found in sickle cell anemias and thalassemia.

The direct Coombs test is used to detect incomplete antibodies already combined with the antigen of red blood cells. The indirect test is used to detect free antibodies in serum. This may be of value in patients suspected of having received incompatible blood, in Rh-negative expectant mothers (bearing Rh-positive infants), and in persons with ABO incompatibilities.

Gamma globulin normal values are 0.8 to 1.30 Gm./100 ml.

Blood cholesterol levels, by a modification of Bloor's method, show a normal range from 130 to 250 mg.%.

Serum calcium levels range from 9.0 to 11.0 mg./100 ml., by the method of Kramer and Tisdall. While calcium is necessary for the conversion of prothrombin to thrombin, there is no real correlation between hypocalcemia and hemorrhagic tendency.

Normal total (30-minute) serum bilirubin levels range from 0.3 to 1.7 mg.%. Direct-reacting (1-minute) bilirubin levels range from 0.1 to 0.5 mg.%. The level of direct-reacting bilirubin diglucuronide is usually normal in hemolytic disease, in which total bilirubin level may range to 6 mg.%.

Alkaline phosphatase values determined by the method of Bodansky range from 1.5 to 4.0 Bodansky units in adults and from 1.5 to 8.0 units in children.

ACUTE PANCREATITIS.—When the diagnosis has been made with reasonable certainty, medical management is to be preferred. Surgery should be reserved for complications or the correction of associated biliary tract disease and, if the patient's condition permits, should be delayed well into convalescence. In general, the preferred medical therapy consists of the following procedures: (1) correction of fluid and electrolyte balance and the administration of whole blood, plasma or plasma expanders or albumin to combat shock (particular attention being paid to correction of calcium deficits in addition to the usual electrolytes); (2) relief of pain with [meperidine] or splanchnic block if necessary; (3) an attempt to antagonize the usual stimulation and ability of the pancreas to secrete, by use of gastric suction, anticholinergics and antacids; (4) administration of broad spectrum antibiotics where indicated. In addition to the above plan of general treatment . . . insulin should be given to control hyperglycemia when present. In our own series, the early administration of insulin seemed to exert a protective effect on the severity of subsequent diabetes.—P. L. Shallenberger, M.D., and D. F. Kapp, M.D., Acute Pancreatitis: A Clinical Review of 72 Attacks Occurring in 54 Patients, *Annals of Internal Medicine,* June, 1958.

MEDICAL CERTIFICATION OF ABSENCE FROM WORK

PROBLEMS often arise between the in-plant medical director and the family physician, especially concerning the reasons for an employee's absence and his ability to return to work. Because of this situation, of particular importance to the private practitioner is the medical certification substantiating illness that many companies require an employee to submit on his return to work. These are usually completed by the employee's personal physician. However, such certificates are not infrequently requested of a physician who has had no previous contact with the worker.

Two situations surround the presentation of these medical "notes" to explain job absence. The first is where the worker has not actually seen a physician during his illness. The second is where the worker was actually under a physician's care during the time he was ill.

In the first instance, the worker comes to the doctor's office and relates his recent medical history and requests certification based on his "self-diagnosis." Rarely does he still show physical evidence of having been sick. How can the physician medically certify to the employer, or to the physician in charge of the in-plant medical program, the absence of this worker who states how sick he has been, especially since the physician did not witness or treat his illness? In this situation should not management or the plant's medical director receive only a statement to the effect that the worker was not seen or treated during his alleged illness? Can a credible diagnosis be made without signs and symptoms, and would the same method of diagnosis be used in the case of a person who does not need certification?

Malingering surely occurs and basically it may be a medical problem. Repeated work absences may well be a manifestation of a condition requiring professional care. The employer should determine whether a worker's absence is habitual, but it is through cooperation between the physician in industry and the private practitioner that the need for medical investigation can be established. The doctor who, only on the basis of a worker's own say-so, concludes a worker was ill, may be doing that worker a great disservice by perpetuating a mental or physical condition requiring medical care.

The second type of situation relating to the medical certificate covering work absence is where the worker was actually under a physician's care during his illness. Here, where there is a diagnosis, how much information should be furnished the employer as to the nature of the employee's illness? This is information that could be considered of a privileged nature. At this point, the physician must give thought as to whether his patient can return to the same duties he performed prior to his illness. If only "light" work is permissible, there must be a mutual interpretation as to the limitations imposed. The physician must also determine whether the illness his patient has suffered was, and might still be, communicable. Additionally, he must determine what effect this illness may have on the attitude of the returning worker toward his fellow employees, as well as their attitude toward him, and how these attitudes may affect the morale, productivity, and safety of the group. To understand the possible long-term effects of such attitudes is as important as returning the employee to his job.

These examples should point up the need for the most effective communication possible between the industrial physician and the physician in private practice. In this issue of THE JOURNAL, page 1131, is a special article demonstrating the private practitioner's involvement in the absence-from-work problem and emphasizing that his is a central role. To be sure, the certification of work absence is only one of the many facets of the problem that will have to be investigated. The type, and perhaps the limitation, of medical certification of job absence certainly needs study by all concerned. But to properly study even this one aspect of the problem, the physician should also have knowledge of the many other pertinent elements that enter into the over-all picture, particularly that of the occupational environment. The study of this problem, and the publication and utilization of its results, promise nothing but improvement of the health of the worker.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

What marks a profession? A profession is defined as a group of individuals who do the same kind of work, who follow definite rules of practice, and who as an organized group uphold and enforce certain moral, ethical, and educational standards in the interests of providing better service to the public.

Since the time of Hippocrates medicine has merited the term "profession." Traditionally, it has had a singular devotion and dedication to the prevention and alleviation of man's physical and mental ills and to the promotion and maintenance of the highest standards.

What must medicine and its members do in this modern, changing age to perform their duties in the best professional manner? I firmly believe that medicine is obligated to provide the best quality of service, traveling that second mile as often as is necessary. It is obligated to assure the public of the competence of its members and the quality of their work. It is obligated to assume the responsibility of disciplining those who do not measure up to the accepted ethical practices of the profession.

If medicine is to fulfill these obligations as a profession, it must remain an organization of individuals. Only physicians, as medical personalities, can establish a close relationship with a patient, can judge the competence of their colleagues, and can prohibit the kinds of conduct harmful to patients and the profession.

An impersonal group, outside of medicine, cannot establish and maintain the high moral rules of the medical profession. It cannot have the conscience of the individual professional man, and it cannot acquire the human understanding needed to maintain the best quality of medical service. It cannot command the confidence of the public.

Of course, a physician may momentarily lose his sense of moral duty to the individual patient. When he does, however, our moral standards suffer and society's confidence in the medical profession is shaken. This gives outside forces an opportunity to promote themselves at the expense of the entire profession.

When patients become skeptical or have reservations about physicians, they are likely to loosen their grip on their traditional right to select the physician they want. If others then assume this right of the patient to choose, the results could be disastrous for medicine as a profession.

For centuries free choice to the profession and to the individual physician has meant the challenge of the open market, the incentive of competitive selection, the chance to succeed or fail based on the judgments of many individual consumers, and the opportunity to develop a relationship with the patient undisturbed by outside forces of uncertain motivation. These have been the rewards of professionalism, justly due where justly deserved.

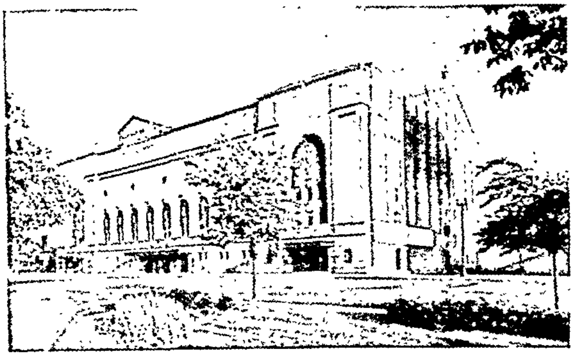
Consequently, each physician must adhere to the best medical practices and the highest moral standards for the protection of himself, his colleagues, and his profession and for the continuing good service to the patient. In this way he will fortify the natural inclination of the patient to preserve his right to choose.

In his book, "The Ethical Basis of Medical Practice," Willard L. Sperry, dean of the Harvard Divinity School, says that "the ethics of accepted medical usage represents both in theory and in general practice the highest professional standard now recognized in our country . . . if the doctors fail us, morally, the whole level of our professional morals will suffer accordingly. We look to them for leadership." Let us not fail this trust.

Gunnar Gundersen, M.D.
La Crosse, Wis.

WELCOME TO BEAUTIFUL MINNEAPOLIS

The more than a half-million people in Minneapolis have joined hands with mother nature to make that city one of the most beautiful in the United States. The natural beauty of Minneapolis is breathtaking. The mighty Mississippi flows there over the historic St. Anthony Falls and through gorges worn deep through centuries of time. Within the city limits are 22 lakes and lakelets providing ideal facilities for boating, bathing, and fishing. The Minneapolis park system is one of the best, with its 152 parks covering nearly 6,000 acres. There is one acre of park for every 98 people in the city. Minnehaha Park, home of the famous falls which Longfellow commemorated in his poem, "The Song of Hiawatha," covers 144 acres of wooded hills and its Parkway winds along the creek, linking Lake Nokomis, Lake Hiawatha, Lake Calhoun, Lake Harriet, Lake of the Isles, and Cedar Lake.



Minneapolis Municipal Auditorium

In this beautiful setting, doctors from throughout the United States will convene Dec. 2-5 to attend the Annual Clinical Meeting of the American Medical Association. In the Municipal Auditorium, shown on this page, they will attend lectures by widely known medical speakers, study hundreds of scientific and commercial exhibits, attend Section meetings, and view an especially selected program of medical films.

Minneapolis is not only one of America's most scenic metropolitan centers; it is also a great industrial center. The flour mills of Minneapolis have been known throughout the world for more than 70 years. A flour mill was one of the first structures to be erected on the banks of the Mississippi in a settlement that later became the city of Minneapolis. The manufacture of linseed products is a leading industry. Huge crushing plants turn out linseed oil by the carload and that helps the paint business there to turn out 6 million gallons of paint a year.

The very impressive business district of Minneapolis is conveniently laid out. Hennepin Avenue, named after the discoverer of St. Anthony Falls, has been called the "Broadway of Minneapolis," and Nicollet Avenue, named after another distinguished pioneer, is justly referred to as the "Fifth Avenue of the upper midwest," where many fine shops and stores offer a fine selection of gifts and other merchandise.

Agricultural machinery, air conditioning equipment, motors, generators, transformers, hearing aids, thermostats, and heat and humidity controls are produced in large quantities. Minneapolis is one of the largest printing and publishing centers in the United States, and, as an apparel manufacturing center, it has often been called the lingerie center of the world.

To serve these thriving industries, the city of lakes has a vast network of railroads, airlines, trucklines, and buslines and a regular barge service down the river to New Orleans during the navigation season.

Unparalleled cultural advantages are afforded by the University of Minnesota, which is among the leading educational institutions of the world, in size, standing, and prestige. The renowned Minneapolis Symphony Orchestra, founded in 1903 and now one of the 5 leading orchestras in the world, is at home on the campus of the University of Minnesota, in the beautiful Northrop Memorial Auditorium.

Visitors may enjoy other cultural facilities such as the Walker Art Center, the Minneapolis Institute of Art, the Swedish-American Museum, and the University of Minnesota Gallery.

Minneapolis is a mecca for tourists and convention delegates, some 300 conventions being held there each year; and it is the gateway to the northern resort country. Minnesota has nearly 2,500 resorts where tourists can go for recreation. Information concerning the numerous points of interest and the many resorts nearby in the state of Minnesota may be obtained from the Minneapolis Area Chamber of Commerce, 701 Second Avenue South, telephone Fe 9-8521.

THE CLINICAL MEETING

AMERICAN MEDICAL ASSOCIATION

Minneapolis, Dec. 2-5, 1958

OFFICIAL CALL

To the Officers and Members of the
American Medical Association

The Clinical Meeting of the American Medical Association will be held in Minneapolis, Dec. 2-5, 1958.

House of Delegates: The House of Delegates will convene at 9 a. m. Tuesday, Dec. 2, in the Illinois, Minnesota, and Wisconsin Rooms of the Leamington Hotel. In the House the representation of the various constituent associations for the 1958 Clinical Meeting is as follows:

Alabama	2	Montana	1
Alaska	1	Nebraska	2
Arizona	1	Nevada	1
Arkansas	2	New Hampshire	1
California	16	New Jersey	6
Colorado	2	New Mexico	1
Connecticut	3	New York	17
Delaware	1	North Carolina	3
District of Columbia	2	North Dakota	1
Florida	3	Ohio	8
Georgia	3	Oklahoma	2
Hawaii	1	Oregon	2
Idaho	1	Pennsylvania	11
Illinois	10	Puerto Rico	1
Indiana	4	Rhode Island	1
Iowa	3	South Carolina	2
Isthmian Canal Zone	1	South Dakota	1
Kansas	2	Tennessee	3
Kentucky	2	Texas	7
Louisiana	2	Utah	1
Maine	1	Vermont	1
Maryland	2	Virginia	3
Massachusetts	6	Washington	3
Michigan	6	West Virginia	2
Minnesota	4	Wisconsin	4
Mississippi	2	Wyoming	1
Missouri	4		

The scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy, the Medical Corps of the Air Force, the Public Health Service, and the Veterans Administration are entitled to one delegate each.

Meetings and Exhibits: The scientific meetings and the scientific and industry exhibits will be held in the Municipal Auditorium.

The Opening General Assembly will begin at 9:30 a. m., Tuesday, Dec. 2, in the Municipal Auditorium.

The Scientific Program will open Tuesday, Dec. 2, at 10:30 a. m., and will continue throughout the afternoon of that day. The program will continue on Wednesday and Thursday, Dec. 3 and 4, and on Friday morning, Dec. 5, closing at 12 noon.

Registration: The Registration Bureau, which will be located in the Municipal Auditorium, will be open as follows:

Tuesday, Dec. 2–8 a. m. - 5:30 p. m.
Wednesday, Dec. 3–8:30 a. m. - 5:30 p. m.
Thursday, Dec. 4–8:30 a. m. - 5:30 p. m.
Friday, Dec. 5–8:30 a. m. - 12 noon

Gunnar Gundersen, President.
E. Vincent Askey, Speaker, House of Delegates.
R. M. McKeown, Secretary-Treasurer.

REFERENCE COMMITTEES OF THE HOUSE OF DELEGATES

The Speaker of the House of Delegates, Dr. E. Vincent Askey, *California*, has appointed the following delegates to serve on the reference committees of the House at the Minneapolis meeting:

Amendments to the Constitution and Bylaws

Donovan F. Ward, *Chairman,* Iowa
Norman S. Moore, New York
Henry Gibbons III, California
Frank J. Holroyd, West Virginia
L. O. Simenstad, Wisconsin

Board of Trustees and Secretary, Reports of

Eugene P. Pendergrass, *Chairman,* Section on Radiology
R. T. Holden, Washington, D. C.
P. Stanley Kneeshaw, California
Charles G. Hayden, Massachusetts
A. H. Aaron, New York

Credentials

A. A. Lampert, *Chairman*, South Dakota
Spencer A. Kirkland, Georgia
Stanley B. Weld, Connecticut
Wm. Weston Jr., South Carolina
Durward G. Hall, Missouri

Executive Session

Gordon F. Harkness, *Chairman*, Section on Laryngology, Otology and Rhinology
Donald Cass, California
Percy Hopkins, Illinois
Vincent W. Archer, Virginia
Philip H. Jones, Louisiana

Hygiene, Public Health, and Industrial Health

Wm. F. Brennan, *Chairman*, Pennsylvania
George D. Johnson, South Carolina
Earl F. Leininger, Nebraska
Edw. P. Flood, New York
Donald A. Charnock, California

Insurance and Medical Service

John S. De Tar, *Chairman*, Michigan
Thurman B. Givan, New York
J. W. Hurff, New Jersey
H. R. McCarroll, Section on Orthopedics
Chas. L. Hudson, Ohio

Legislation and Public Relations

Francis T. Holland, *Chairman*, Florida
Paul D. Foster, California
J. Arnold Bargen, Minnesota
G. C. Engel, Pennsylvania
Leo E. Gibson, New York

Medical Education and Hospitals

Grover C. Penberty, *Chairman*, Section on Surgery
Wesley W. Hall, Nevada
Peter M. Murray, New York
J. M. Pfeiffenberger, Illinois
Millard D. Hill, North Carolina

Medical Military Affairs

H. Thos. McGuire, *Chairman*, Delaware
Archie O. Pitman, Oregon
W. V. Pierce, Kentucky
L. C. Heare, Texas
Stuart T. Ross, Section on Gastroenterology and Proctology

Miscellaneous Business

Chas. F. Strosnider, *Chairman*, North Carolina
G. B. Wilder, Indiana
Jos. B. Copeland, Texas
Philip P. Thompson, Maine
Wm. F. Costello, New Jersey

Reports of Officers

Earl W. Mericle, *Chairman*, Indiana
B. E. Montgomery, Illinois
L. R. Pyle, Kansas
Louis W. Jones, Pennsylvania
L. R. Dame, Massachusetts

Rules and Order of Business

Ezra A. Wolff, *Chairman*, New York
E. B. Robinson, Jr., Alabama
L. C. Theobold, New Hampshire
Everett P. Coleman, Illinois
George A. Earl, Minnesota

Sections and Section Work

H. Kenneth Scatliff, *Chairman*, Illinois
W. A. Showman, Section on Dermatology
K. B. Castleton, Utah
J. W. Read, Washington
Dan H. Bee, Pennsylvania

Tellers

Edward E. H. Munro, *Chairman*, Colorado
Earl Malone, New Mexico
Albert T. Sudman, Wyoming
Milo Fritz, Alaska
James Feldmayer, California

Sergeants at Arms

C. Paul White, *Master*, Illinois
F. Sánchez-Castaño, Puerto Rico

H. T. Carmichael	Chicago, 1961
M. R. Kaufman	New York, 1962
R. J. Plunkett, Secretary	Chicago

The Executive Vice-President, Assistant Executive Vice-President, and Editor are ex officio *members of all Standing Committees.*

HOUSE OF DELEGATES

The House of Delegates will convene at 9 a. m. Tuesday, Dec. 2, 1958, in the Illinois, Minnesota, and Wisconsin Rooms at the Leamington Hotel.

The Reference Committee on Credentials will meet near the entrance to the Illinois, Minnesota, and Wisconsin Rooms at 8 a. m. Tuesday, Dec. 2. Credentials should be presented to the Reference Committee on Credentials as early as possible, so that the official roll of the House may be prepared and the House of Delegates may organize promptly and proceed with its business. The Reference Committee will also meet preceding each subsequent meeting of the House of Delegates.

Each delegate should present properly executed credentials signed by the president or secretary of the constituent association, by the chairman or secretary of the section, or by the surgeon general or chief medical director of the government service he represents. Alternates presenting credentials should see that the delegates whose places they are to take have signed the alternate authorization.

Each delegate, *before* registering with the Reference Committee on Credentials, should register for the Scientific Assembly at a desk near the entrance to the Illinois, Minnesota, and Wisconsin Rooms.

Meeting rooms have been provided for the use of Reference Committees of the House of Delegates. Reference Committee meetings must be held at the time and in the room assigned so that any who are interested in referred matters may appear before the committees.

Typists will be available in the Secretary's Office (Dakota Room) for preparing official reports, resolutions, and motions.

REGISTRATION

The Registration Bureau, which will be located in the Municipal Auditorium on East Grant between Stevens Avenue and Third Avenue, will be open as follows:

Tuesday, Dec. 2–8 a. m.–5:30 p. m.
Wednesday, Dec. 3–8:30 a. m.–5:30 p. m.
Thursday, Dec. 4–8:30 a. m.–5:30 p. m.
Friday, Dec. 5–8:30 a. m.–12 noon

An information window will be operated in connection with the Registration Bureau.

Who May Register

Members—Active, Affiliate, Associate, Service and Honorary—and invited guests may register for attendance at meetings.

Residents, interns, senior medical students, Student A. M. A. members, and registered nurses will be given registration cards at a designated window. These should be filled in and presented at the window indicated, together with their professional identification or a card or letter signed by the superintendent of the hospital where they are registered or the dean of the medical school they attend.

Register Early

The Registration Bureau will be open at 8:00 a. m. on Tuesday, Dec. 2. Members are urged to take advantage of this early opening.

The names and convention or local addresses of those who register will be included in the *Daily Bulletin*. This will enable visiting physicians to find friends who have registered.

Suggestions That Will Facilitate Registration

Members who have Advance Registration Cards can be processed with little or no delay, if the name of your convention hotel or local address and the number of guests you wish to admit are filled in prior to registering.

Present completed card at windows marked "Advance Registration" and you will receive a badge and a copy of the Official Program.

If you do not have an Advance Registration Card and wish us to send one to you, just fill out the form on advertising page 45 and return it before Nov. 7, 1958, to the American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

Members without Advance Registration Cards will find blank cards to fill in on tables near the registration windows. The filled-in card should be presented, together with your American Medical Association Membership pocket card, at the window indicated. Your pocket card will be returned to you and you will receive a badge and a copy of the Official Program.

Registration at Leamington Hotel

General Officers of the American Medical Association, members of the House of Delegates, alternate delegates, and the president, president-elect, and constitutional secretary of the constituent medical societies may register at the Leamington Hotel. Advance registration facilities will be set up on Sunday and Monday in the Secretary's Office in the Dakota Room at the Leamington Hotel; Tuesday, Dec. 2, beginning at 8 a. m. registration will be held near the entrance to the Illinois, Minnesota, and Wisconsin Rooms.

Delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House, which will convene at 9 a. m., Tuesday, Dec. 2.

Medical Society Executives Registration

Staff members of state, territorial, and county medical societies, editors of state medical journals and county medical society bulletins, and staff members of national organizations of medical interest may register beginning on Sunday, Nov. 30, in the Secretary's Office in the Dakota Room at the Leamington Hotel.

MEETING PLACES

House of Delegates: Illinois, Minnesota, and Wisconsin Rooms of the Leamington Hotel, Third Avenue, Tenth and Eleventh Streets.

General Scientific Meetings: Municipal Auditorium, East Grant between Stevens Avenue and Third Avenue.

Motion Pictures: Municipal Auditorium.

Color Television: Municipal Auditorium.

General Headquarters, Registration Bureau, Scientific Exhibit, Industry Exhibit and Information Bureau: Municipal Auditorium.

MINNEAPOLIS HOTEL RESERVATIONS

If hotel accommodations have not yet been secured, it is suggested that the application form which may be found on advertising page 108 of this issue of The Journal be filled in and sent directly to the A. M. A. Clinical Meeting Housing Bureau, 6th floor, Lutheran Brotherhood Bldg., Minneapolis 2, Minn. Applications for hotel accommodations should *not* be sent to the American Medical Association office in Chicago as it delays receipt of the application by the A. M. A. Housing Bureau and its subsequent processing.

WOMAN'S AUXILIARY

A cordial invitation is extended to the wives of physicians attending the A. M. A. Clinical Session in Minneapolis to participate in the program planned by the Woman's Auxiliary to the Minnesota State Medical Association.

The information booth will be in the Minneapolis Auditorium (main floor) and will be staffed by members of the Woman's Auxiliary to the Hennepin County Medical Society. The following program has been planned and all visiting ladies are cordially invited:

Tuesday, December 2

Afternoon: Tea at the American Swedish Art Institute. Transportation furnished by the Woman's Auxiliary to the Ramsey County Medical Society. Cars will leave from Hotel Leamington.

Evening: Program by "Doc" Evans and his Dixieland Band—an interesting history of Jazz demonstrated by music.

Wednesday, December 3

Morning: Tour of Southdale Shopping Center.
Luncheon at a nominal charge.

Afternoon: Tour of Betty Crocker Kitchens and General Mills new building.
Transportation will be furnished for the above. Cars will leave from Hotel Leamington.

Evening: House of Delegates Dinner.

Thursday, December 4

Morning: *Tours to be announced.*
Evening: *Concert by the Apollo Club.*
Complete details available at the information desk.

THE SCIENTIFIC PROGRAM

MINNEAPOLIS AUDITORIUM

The Scientific Program for the Minneapolis Clinical Meeting is of exceptionally high caliber and should be of interest to general practitioner and specialist alike.

Minneapolis Auditorium will be the scene of lectures, panels, symposiums, motion pictures, color television, and the Scientific Exhibit. Color television will originate at the Mayo Memorial Building, University of Minnesota Hospital, and will be carried by closed circuit to the Auditorium.

A Trans-Atlantic Conference with the British Medical Association, which will hold its first Clinical Meeting in Southampton, England, at the same time as the Clinical Meeting of the American Medical Association, will be held in the Minneapolis Auditorium at 10 a. m. Friday, Dec. 5 (4 p. m. in Southampton).

Scientific activities outside the Auditorium include 10 round table breakfasts on Thursday morning at the Leamington Hotel, which will be limited to 30 persons each, and to which admission will be by ticket only. Speakers and topics will be announced in a later edition of The Journal. On Wednesday evening an outstanding motion picture program will be presented at the Leamington Hotel, in the Michigan Room.

The Council on Scientific Assembly extends its appreciation to the Local Committee on Arrangements in Minneapolis for its painstaking initiative in preparing the program. Dr. O. L. Norman Nelson, General Chairman of Arrangements; Dr. N. L. Gault Jr., Chairman, Committee on Scientific Program; Dr. James R. Fox, Television Chairman, and Dr. Arnold J. Kremen, Scientific Exhibit Chairman, have all been exceedingly active during the last year. Others deserving mention include Dr. Thomas A. Peppard, in charge of the Special Exhibit on the History of Medicine in Minnesota; Dr. Mancel T. Mitchell, in charge of the Manikin Demonstrations on Problems of Delivery, Mr. Thomas P. Cook, and Mr. R. R. Rosell, Executive Assistants.

Appreciation is also extended to Smith, Kline & French Laboratories, Philadelphia, for its part in the presentation of the color television program and the Trans-Atlantic conference.

The program begins Tuesday morning, Dec. 2, and continues until Friday noon, Dec. 5.

OPENING GENERAL ASSEMBLY: ROOM 2

Tuesday morning, Dec. 2

Presiding: O. L. Norman Nelson, Minneapolis,
General Chairman

9:30 Speakers:
Horatio B. Sweetser, Minneapolis, President, Minnesota State Medical Association.
R. S. Ylvisaker, Minneapolis, President, Hennepin County Medical Society.
Robert N. Barr, Minneapolis, Secretary, Minnesota State Board of Health.
N. L. Gault Jr., Minneapolis, Chairman, Local Committee on Scientific Program.
Charles W. Mayo, Rochester, Minn., The Mayo Clinic.
Gunnar Gundersen, La Crosse, Wis., President, American Medical Association.

Meningitis Due to ECHO Viruses.
Tom D. Y. Chin and Michael L. Furcolow, Kansas City, Kan.

11:00 The Emergency Treatment of Massive Upper Gastrointestinal Hemorrhage by Local Gastric Hypothermia.
O. H. Wangensteen, H. D. Root, P. A. Salmon, and W. O. Griffen Jr., Minneapolis.

11:30 The Physical Treatment of Peripheral Nerve Injuries.
Robert W. Boyle, Milwaukee.

LECTURES: ROOM 2

Tuesday afternoon, Dec. 2

1:30 Tinnitus, Vertigo, and Deafness.
L. R. Boies, Minneapolis.

2:00 Head and Neck Tumors.
Danely P. Slaughter, Chicago.

2:30 How to Examine and Manage the Acute Back.
Edward H. Juers, Red Wing, Minn.

3:00 Tendon Repair of the Hand.
Robert E. Van Demark, Sioux Falls, S. D.

3:30 Prescription of Activities for Cardiac Convalescents.
Edward E. Gordon, Chicago.

4:00 Asian Influenza and Its Complications.
Wendell Hall, Minneapolis.

4:30 Treatment of Cardiac Arrhythmias.
George A. Hellmuth, Milwaukee.

Wednesday morning, Dec. 3

9:00 Fractures in Children.
Donald S. Miller, Chicago.

9:30 When to Do What in Children's Surgery.
H. Wm. Clatworthy Jr., Columbus, Ohio.

10:00 The Diagnosis and Treatment of Rectal Neoplasms.
Lloyd F. Sherman, Minneapolis.

3:30 Practical Aspects of Management of Urinary Tract Infections.
E. N. Cook, Rochester, Minn.

4:00 Premature Infant Feeding.
Hans G. Keitel, Philadelphia.

4:30 Ocular Injuries.
Dan M. Gordon, New York.

Thursday morning, Dec. 4

9:00 Obstetrical Anesthesia and Analgesia.
Virginia B. Hartridge, Rochester, Minn.

9:30 Abnormal Uterine Bleeding.
Roy Holly, Omaha.

10:00 Postsurgical Fluid Balance.
Philip Thorek, Chicago.

10:30 Some Newer Concepts in the Treatment of Allergy.
J. S. Blumenthal, Minneapolis.

11:00 Significance of Routine Urinalysis.
George E. Schreiner, Washington, D. C.

11:30 Prostatism in the Young and Aged.
James W. Sargent, Milwaukee.

Thursday afternoon, Dec. 4

1:30 Newer Phenothiazine Drugs in Nervous Disorders.
V. John Kinross-Wright, Houston, Texas.

2:00 Use and Abuse of Blood Transfusions.
Virgil Loeb Jr., St. Louis.

2:30 Chronic Relapsing Pancreatitis.
James J. Priestley, Rochester, Minn.

3:00 Strictured Common Bile Duct.
Stanley R. Friesen, Kansas City, Kan.

3:30 Office Use of the Ophthalmoscope.
John P. Wendland, Minneapolis.

4:00 Convulsive Disorders.
Edward C. Clark, Rochester, Minn.

4:30 The Diarrhea of Travelers to Mexico.
B. H. Kean, New York.

Friday morning, Dec. 5

9:00 Carotid Artery Thrombosis.
Clark H. Millikan, Rochester, Minn.

9:30 Recent Advances in the Treatment of Acute Renal Failure.
Francis D. Murphy and Earl G. Schulz, Milwaukee.

10:00 Treatment of Pulmonary Emphysema.
George N. Bedell, Iowa City.

10:30 Practical Aspects of Treatment of Congestive Heart Failure.
C. Thorpe Ray, Columbia, Mo.

11:00 Farmer's Lung (Silo-Filler's Disease)
Thomas Lowry, Minneapolis.

11:30 Current Management of Gouty Arthritis.
John H. Talbott, Buffalo.

Medical Management.
James B. Carey Jr., Minneapolis.
Surgical Management.
Monford D. Custer, Winchester, Va.

10:30-12:00
Symposium on Hypertension—Medical and Surgical
Does Hypertension Need Treatment?
Louis J. Tobian Jr., Minneapolis.
Optimal Medical Management.
Harriet P. Dustan, Cleveland.
Is There a Place for Surgery in the Treatment of Hypertension?
Jesse E. Thompson, Dallas, Texas.

1:30-4:00
Rheumatic Fever—Surgical Aspects.
Richard L. Varco, Minneapolis, Chairman.

This is essentially a postgraduate course directed toward the general practitioner. It will be presented in a concise, informative, and visual manner for active use in the general practice of medicine. The demonstrations will include the actual heart sounds and murmurs, cardiac catheterization, laboratory procedures, and the usual electrocardiograms, and x-rays.

Thursday morning, Dec. 4

9:30-10:30
Cesarean Section.
John L. McKelvey, Minneapolis, Chairman.
Participants: Irwin H. Kaiser, Minneapolis, and others.

10:30-12:00
Arthritis.
Paul Bilka, Minneapolis, Chairman.

Thursday afternoon, Dec. 4

1:30-2:45
Evaluation of Limb and Back Disability—A Practical Demonstration of the Office Evaluation..
Carl O. Rice, Minneapolis, Chairman.
Medicolegal Problems.
Brent McLeod, Minneapolis.
Disability in the Fingers and Hand.
J. H. Strickler, Minneapolis.
Disability in the Arm.
Albert Hays, Minneapolis.
Disability in the Leg.
Lester Carlander, Minneapolis.
Disability in the Back.
Quenton W. Mack, Boise, Idaho.

2:45-4:00
Emergency Procedures Commonly Encountered in the Care of Children.
Tague Chisholm, Minneapolis, Chairman.

Determination of the fluids indicated and the manner of administration, spinal taps, and the like.

Friday morning, Dec. 5

11:00-12:00
Medical Frontiers.
W. Albert Sullivan Jr., Minneapolis, Chairman.

There will be 5-min. capsule vignettes with demonstrations of current research. These will present the potentials of application to the practice of medicine.

TRANS-ATLANTIC MEDICAL CONFERENCE: ROOM 1

Friday, Dec. 5

American Medical Association Clinical Meeting, Minneapolis,
British Medical Association Clinical Meeting,
Southampton, England.

Presented in cooperation with Smith, Kline & French Laboratories, Philadelphia

10:00-11:00 a. m. (Central Standard Time)
4:00-5:00 p. m. (Greenwich Time)

Clinical Pathological Conference on Chest Diseases

Arrangements have been made by James Rogers Fox, Minneapolis, Chairman of the American Committee, and Walter Hedgcock, Assistant Secretary of the British Medical Association, for a Trans-Atlantic clinical pathological conference on chest diseases.

There will be a moderator and two clinicians for each group. During the first half hour, the British Medical Association will present cases with discussion by a two-way radio connection. The second half hour will be used by the American Medical Association for the presentation of cases, followed by a discussion between both groups.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will be located on the lower level of Minneapolis Auditorium, with access from the Industry Exhibits by stairs and ramps.

In addition to 98 individual scientific exhibits, the Council on Scientific Assembly has arranged several special features, including the Special Exhibit on Fractures, Special Exhibit on History of Medicine, and Manikin Demonstrations on Problems of Delivery.

PROBLEMS OF DELIVERY—MANIKIN DEMONSTRATIONS

Space 109

Manikin demonstrations on problems of delivery will be conducted at stated intervals throughout the week. An opportunity for questions and answers will be given following each demonstration.

Mancel T. Mitchell, Minneapolis, is in charge of the demonstrations. The following schedule will be presented:

Tuesday afternoon, Dec. 2

12:30 Forceps Deliveries.
Maxwell M. Barr, Minneapolis.
4:30 Breech Deliveries.
Charles H. McKenzie, Minneapolis.

Wednesday morning, Dec. 3

10:00 Breech Deliveries.
Richard R. Fliehr, Minneapolis.

Wednesday afternoon, Dec. 3

12:30 Forceps Deliveries.
Oliver H. Peterson Jr., Bismarck, N. D.
4:30 Forceps Deliveries.
Robert M. Wagner, Minneapolis.

Thursday afternoon, Dec. 4

12:30 Forceps Deliveries.
Owen F. Robbins, Minneapolis.
4:30 Breech Deliveries.
Melvin B. Sinykin, Minneapolis.

Friday morning, Dec. 5

9:30 Forceps Operations and Breech Deliveries.
Konald A. Prem, Minneapolis.

SPECIAL EXHIBIT ON HISTORY OF MEDICINE IN MINNESOTA

Spaces 303-306

The Special Exhibit on History of Medicine in Minnesota has been prepared by a committee of which Thomas A. Peppard, Minneapolis, is Chairman.

The exhibit presents the following:

1. History of Indian Medicine in Minnesota, arranged under the direction of H. Kleinman, Minneapolis.
2. History of the Mayo Clinic, arranged under the direction of Arthur B. Hunt and Arthur H. Bulbulian, Rochester, Minn.

3. History of the University of Minnesota.
4. Illustrations showing the progress of Minneapolis hospitals.

SPECIAL EXHIBIT ON FRACTURES

Spaces 401-404

The Special Exhibit on Fractures is presented under the auspices of the following committee:

Ralph G. Carothers, Cincinnati, Chairman.
Harry B. Hall, Minneapolis.
Charles V. Heck, Chicago.

Continuous demonstrations will be conducted daily from 10 a. m. to 12 noon and from 2 to 4 p. m., Tuesday morning to Friday noon on the following subjects:

Fractures Encountered by the Front Seat Passenger in a Crash.
Fractures of the Hip.
Fractures of the Ankle.

Basic principles will be stressed and ample opportunity will be allowed for questions. Members of the committee will be present to discuss individual problems with visiting physicians. A pamphlet giving the essential features of the exhibit will be distributed. The following surgeons will assist the committee in the presentation of the exhibit:

Roy E. Brackin, Winnetka, Ill.
Wesley H. Burnham, Minneapolis.
Charles DeBold Jr., Poughkeepsie, N. Y.
Nicholas J. Giannestras, Cincinnati.
Kenneth T. Hubbard, Oak Park, Ill.
Richard H. Jones, Minneapolis.
Edward H. Juers, Red Wing, Minn.
William J. Kisiel, Springfield, Mass.
John F. Lyford III, Hines, Ill.
Andrew R. Mailer, Poplar Bluff, Mo.
Glenn Moore, Flint, Mich.
Roland F. Neumann, Minneapolis.
Frank G. Ober, Burlington, Iowa.
Frederick G. Rosendahl, Minneapolis.
Edmund T. Rumble Jr., Callicoon, N. Y.
Harley M. Sigmond, Evanston, Ill.
Garland F. Smith, St. Louis.
Franklin V. Wade, Flint, Mich.
H. L. Wormhoudt, Ottumwa, Iowa.

OBSTETRICS AND GYNECOLOGY

Space 103

Perphenazine Intramuscularly in Labor.

T. G. Gready Jr., W. J. Estrada, and Joe B. Haden, Houston, Texas.

Space 104

The Psychic Factor in Prenatal Symptomatology.

Henry A. Belafsky, Samuel Breslow, Jack E. Shangold, and Leonard M. Hirsch, Perth Amboy General Hospital, Perth Amboy, N. J.

Space 105

Perinatal Mortality Pathology.

Frederick H. Falls and Charlotte S. Holt, Illinois State Department of Public Health, Chicago.

Space 106

Clinical Evaluation of Oxytocics.

William J. Fitzgerald, A. N. Brady Maternity Hospital and Albany Medical College, Albany, N. Y.

Space 107

Care and Comfort of the Postpartum Patient.

C. Donald Kuntze, New York.

Space 108

Evaluation of Synthetic Oxytocics in Obstetrics.

Herschel S. Murphy and Ernest C. Lowenstein, Rahway Hospital, N. J.; Archibald K. Maness, Cone Memorial Hospital, Greensboro, N. C.; and Floyd D. Gindhart, McKinley Hospital, Trenton, N. J.

Space 110

Synthetic Oxytocin.

Edward H. Bishop and Paul Stroup, Pennsylvania Hospital, Philadelphia.

SURGERY

Space 111

Management of the Patient Undergoing Open Heart Surgery.

C. W. Lillehei, Herbert E. Warden, Richard A. DeWall, Vincent L. Gott, Paul C. Hodges Jr., David M. Long, Paul Adams, Ray C. Anderson, Richard L. Varco, and Owen H. Wangensteen, University of Minnesota Medical School, Minneapolis.

Space 112

Surgical Management of Carcinoma of the Rectum and Rectosigmoidal Region.

C. W. Mayo, J. M. Waugh, E. S. Judd Jr., B. M. Black, G. A. Hallenbeck, and O. H. Beahrs, Mayo Clinic and Mayo Foundation, Rochester, Minn.

Space 113

Posterior Vaginal Anus.

Edward J. Donovan, J. Frederick Eagle, and Edward G. Stanley-Brown, St. Luke's Hospital, New York.

Space 114

A Standardized Method for the Production of Reversible or Irreversible Hemorrhagic Shock in Experimental Animals.

Richard C. Lillehei, Ralph R. Rayner, and Lloyd D. MacLean, University of Minnesota Medical School, Minneapolis, and the Ancker Hospital Surgical Research Laboratory, St. Paul; and Albert Einhaber and Robert W. Clarke, Washington, D. C.

Space 115

The Etiology of Aerosinusitis and Its Treatment.

Stanley H. Bear, Maxwell Air Force Base, Montgomery, Ala.

Space 116

Pigeon Toe: Study of Border-Line and Abnormal Postures of the Lower Extremities.

Kenath H. Sponsel, Minneapolis.

Space 117

Control of Tension in General Surgery.

Timothy A. Lamphier, Boston.

Space 118

The Emergency Treatment of Massive Upper Gastrointestinal Hemorrhage by Local Gastric Hypothermia.

Owen H. Wangensteen, Harlan D. Root, Peter A. Salmon, and Ward O. Griffen Jr., University of Minnesota Medical School, Minneapolis.

ARTHRITIS AND RHEUMATISM

Space 122

Salicylate Therapy in Rheumatic Diseases.

Theodore B. Bayles and Heinrich Tenckhoff, Robert Breck Brigham Hospital, Boston.

Space 123

Gold in Rheumatoid Arthritis.

L. Maxwell Lockie and Harold M. Robins, University of Buffalo Medical School, Buffalo.

Space 124

Chloroquine and Hydroxychloroquine in Rheumatoid Disease: Five Years Experience with Continuous Therapy.

A. W. Bagnall, University of British Columbia Medical School, Vancouver, Canada.

Space 126

Intrasynovial Steroid Therapy.

Joseph L. Hollander, Ernest M. Brown Jr., Ralph A. Jessar, Nathan M. Smukler, and J. Rush Shanahan, University of Pennsylvania School of Medicine and Hospital, Philadelphia.

Space 127

Diseases of the Connective Tissues.

Bernard M. Norcross and Salvatore R. LaTona, University of Buffalo School of Medicine and Buffalo General Hospital, Buffalo.

Space 130

Information on Arthritis: Aids to the Physician and Information for the Patient.

Russell L. Cecil and R. W. Lamont-Havers, The Arthritis and Rheumatism Foundation, New York.

Space 131

Improved Anti-Rheumatoid Chrysotherapy.

Richard T. Smith, William P. Peak, Kenneth M. Kron, Irvin F. Hermann, and Russell A. Del Toro, Benjamin Franklin Clinic, Philadelphia.

Space 132

Do You Have a Question, Doctor?

John W. Sigler, Detroit; L. Maxwell Lockie, Buffalo; and Donald F. Hill, Tucson, Ariz.

Space 134

Development of a New Uricosuric Agent.

J. J. Burns, T. F. Yü, Bernard B. Brodie, Alexander B. Gutman, J. Murray Steele, and Murray Weiner, National Heart Institute, Bethesda, Md.

INTERNAL MEDICINE AND THERAPEUTICS

Space 203

Cardiac Glycosides: Therapeutic Application.

Arthur C. DeGraff, New York University College of Medicine, New York.

Space 204

Prednisone Induced Diuresis in Congestive Heart Failure.

Allen D. Riemer, Denver.

Space 206

Returning the Coronary Patient to Productivity.

Shepard Shapiro, New York.

Space 207

Edema Mechanisms and Diuretic Therapy.

John H. Moyer, John R. Beem, Morton Fuchs, Gordon Bendersky, and Lewis C. Mills, Hahnemann Medical College and Hospital of Philadelphia.

Space 208

Streptokinase Buccally in the Treatment of Infection and Edema.

Joseph M. Miller and Milton Ginsberg, Veterans Administration Hospital, Fort Howard, Md.

Space 209

Glucosamine: An Amino-Sugar with Growing Therapeutic Potentialities.

W. C. Gittinger and H. Weiner, Pfizer Laboratories, Brooklyn, N. Y.

Space 210

Antipyretic Therapy in the Febrile Infant: An Everpresent Problem.

A. A. Mintz, F. T. Matthes, and A. L. Megarity, Jefferson Davis Hospital and Baylor University College of Medicine, Houston, Texas.

Space 211

Cycloserine in High Dosage.

Marjorie M. Pyle, William Barclay, John Kasik, and Karl H. Pfuetze, Chicago State Tuberculosis Sanitarium, Chicago.

Space 212

The Improvement of Steroid Preparations.

Hubert C. Peltier, Harold L. Upjohn, Robert O. Stafford, and Robert H. Levin, The Upjohn Company, Kalamazoo, Mich.

Space 213

Formamidinyliminourea (DBI), A New Oral Hypoglycemic Agent: Comparison with Other Blood Sugar Lowering Compounds.

Leo P. Krall, Robert Bradley, and Priscilla White, Joslin Clinic, Boston; Julius Pomeranze and Raymond J. Gadek, New York Medical College, New York; and Charles Weller and Alice Macauley, Grasslands Hospital, Valhalla, N. Y.

Space 216

Preserving the Diabetic Foot from a Triple Threat.

W. L. Lowrie, H. L. Johnson, W. E. Redfern, J. B. Bryan, F. W. Whitehouse, and E. A. Kish, Henry Ford Hospital, Detroit.

Space 217

Misleading Thoracic Roentgenograms.

C. H. Hodgson, J. A. Callahan, A. J. Bruwer, and A. H. Bulbulian, Mayo Clinic and Mayo Foundation, Rochester, Minn.

Space 218

Isolated Organ Perfusion: Chemotherapeutic Application.

J. B. Aust, R. K. Ausman, and W. O. Griffen Jr., University of Minnesota Medical School, Minneapolis.

Space 219

Pulmonary Alveolar Proteinosis: A New Entity.

Samuel H. Rosen, Armed Forces Institute of Pathology, Washington, D. C.; Benjamin Castleman, Massachusetts General Hospital, Boston; and Averill A. Liebow, Yale University School of Medicine, New Haven, Conn.

Space 220

The Hamman-Rich Syndrome: Fibrosing Interstitial Pneumonitis.

H. S. Van Ordstrand, W. R. Biddlestone, L. J. McCormack, and V. E. Reinking, Cleveland Clinic, Cleveland.

GASTROENTEROLOGY

Space 221

Cholecystokinetic Effect of D-Glucitol.

Harry Tirsch, Brooklyn, N. Y.

Space 222

Sustained Release Medication in the Treatment of Gastrointestinal Disturbances.

Frederick Steigmann and Ludwig Kaminski, Cook County Hospital, Chicago.

Space 224

Treatment of Autonomic Symptoms of the Gastrointestinal Tract.

Charles Wm. Smith and Chester G. Thomas, Harrisburg Hospital, Harrisburg, Pa.

Space 225

Evaluation of a New Anticholinergic Agent on the Gastrointestinal Tract of Man.

N. C. Hightower Jr., Scott and White Clinic, Temple, Texas; and M. S. Kleckner Jr., Yale University School of Medicine, New Haven, Conn.

FOODS AND NUTRITION

Space 226

Nutrition: The Core of Growth and Development.

Harold D. Lynch and W. D. Snively Jr., Evansville, Ind.

Space 227

A Practical Approach to Management of Overweight: With Special Reference to a New Non-stimulating Anorectic.

Raymond J. Gadek, Harold S. Feldman, and Ralph Lucariello, New York Medical College, Bird S. Coler Memorial and Flower and Fifth Avenue Hospitals, New York.

Space 228

Effects of Vitamin B_1 and B_{12}: Stimulation of Appetite and Weight Gain in Undernourished Children.

Emanuel Dubow and Robert H. Broh-kahn, Beekman Downtown Hospital, New York.

Space 229

You Can Reduce.

Philip L. White, Eugene H. Stevenson, and Mary Jane Kibler, Council on Foods and Nutrition, American Medical Association, Chicago.

Space 230

A New Dietary Management for Hypercholesterolemia.

P. A. Boyer Jr., J. T. Lowe, R. W. Gardier, and J. D. Ralston, Pitman-Moore Company and Central State Hospital, Indianapolis.

Space 231

Meat in the Diet of Premature Infants: Influence on Red Cell Volume and Hemoglobin Mass.

Thomas R. C. Sisson and L. E. Whalen, University of Rochester School of Medicine and Dentistry, Rochester, N. Y.

Space 232

Oral Iron Absorption in Normal and Iron Depleted Subjects: A Radioisotope Method Using Fe-59.

Donald R. Korst, Veterans Administration Hospital; and Ronald C. Bishop, Simpson Memorial Institute, University of Michigan Medical School, Ann Arbor, Mich.

Space 233

Iron Deficiency States: Treatment with Intramuscular Iron-Dextran Complex.

Harold S. Schiro, Cincinnati.

PSYCHIATRY AND NEUROLOGY

Space 307

Upright Dynamic Myelography.

Bruce N. Kvernland, Ray V. Grewe, and Ivan M. Woolley, Emanuel Hospital, Portland, Ore.

Space 308

Early Diagnosis and Management of Phenylketonuria.

Willard R. Centerwall and Siegried A. Centerwall, College of Medical Evangelists, Los Angeles.

Space 309

Control of Seizures and Hypertonus: Meprobamate in Tetanus, Epilepsy and Cerebral Palsy; An Evaluation.

M. A. Perlstein and Harry Elam, Cook County Hospital, Chicago.

Space 310

Treatment and Rehabilitation of Chronic Schizophrenic Patients.

George W. Brooks, Vermont State Hospital, Waterbury, Vt.; and Francis S. Irons, Vermont Vocational Rehabilitation Division, Montpelier, Vt.

Space 311

The Surgical Treatment of Syringomyelia.

W. James Gardner and Donald F. Dohn, Cleveland Clinic, Cleveland.

Space 312

Continuous Recording of Oxygen Consumption and Gross Body Activity in the Rodent: Metabolic Reactions to Stress and Their Pharmacologic Modification.

David T. Lykken and Godron T. Heistad, University of Minnesota Medical School, Minneapolis.

Space 313

Treatment of Chronic Psychosomatic Disorders in General Practice.

David M. Shoemaker and Fred J. Phillips, Quakertown, Pa.

Space 314

Neurological Examination of Infants.

Paul M. Ellwood Jr., Elizabeth Kenny Institute, University of Minnesota Medical School, Minneapolis.

Space 316

Early and Comprehensive Treatment of Parkinson's Disease.

Lewis J. Doshay, Columbia Presbyterian Medical Center, New York.

Space 317

Studies with TP 21: The Evaluation of a New Tranquilizing Drug.

V. John Kinross-Wright, Baylor University College of Medicine and Houston State Psychiatric Institute, Houston, Texas.

Space 318

Combined Dermatologic and Psychiatric Study of a New Tranquilizer.

Jay Shannon, University of Cincinnati College of Medicine, Cincinnati.

Space 321

Causes and Treatment of Tension in Young Adults.

Elliot J. Margolis, William J. Cauffman, William G. Pauley, and Paul C. Gregg, Levittown, Pa.

HEADACHE

Space 322

Newer Knowledge of Non-Migrainous Headaches.

Adrian M. Ostfeld, University of Illinois Research and Educational Hospitals, Chicago.

Space 324

Frontal Headache.

Henry D. Ogden, Louisiana State University School of Medicine, New Orleans.

Space 325

Headpain.

F. W. Wittich, Minneapolis.

ALCOHOLISM

Space 326

Alcoholism: A Basic Approach to Treatment.

Leon A. Greenberg, Yale Center of Alcohol Studies, New Haven, Conn.

Space 327

Community Roles in the Rehabilitation of the Alcoholic.

J. J. Van Gasse and Edward L. Costello, Wyckoff, N. J.

Space 328

Alcoholism: Alcoholism is Your Business.

Marvin A. Block, Buffalo, Committee on Alcoholism, American Medical Association.

Space 329

A Comparison of Blood Pressure and Pulse Changes: Citrated Calcium Carbimide-Alcohol and Disulfiram-Alcohol Reactions.

Reduction of Intracranial and Intraocular Pressure with Urea.

MANUCHER JAVID, University of Wisconsin Medical School, Madison, Wis.

REPORTS OF OFFICERS

REPORT OF BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

The following annual report of the Board of Trustees is respectfully submitted:

Report on Matters Referred by House of Delegates

All resolutions referred to the Board of Trustees by the House of Delegates at its meeting in June, 1958, have been forwarded to the several councils, committees, and departments of the Association concerned for study. As soon as reports are available from these groups, they will be transmitted to the House of Delegates for action.

Distinguished Service Award

The Board wishes to urge that members of the Association submit nominations for the Distinguished Service award. If possible, these nominations should be received in the office of the Executive Vice-President by March 1.

Annual and Clinical Meetings

The following places and dates have been selected for the Annual and Clinical Meetings of the Association:

Annual Meetings:	1959—Atlantic City, June 8-12
	1960—Miami Beach, June 13-17
	1961—New York, June 19-23
Clinical Meetings:	1959—Dallas, Dec. 1-4
	1960—Washington, D.C., Nov. 29-Dec. 2
	1961—Denver, Nov. 28-Dec. 1

Reorganization

From June, 1957, to Dec. 31, 1957, the position of General Manager was filled by Dr. George F. Lull, who became Assistant to the President on Jan. 1, 1958. Dr. F. J. L. Blasingame became the General Manager on Jan. 1, 1958, and conducted the administrative affairs of the Association in that capacity until the meeting of the House of Delegates in San Francisco in June when, by action of the House, the position of General Manager was eliminated and that of Executive Vice-President was substituted. The Board of Trustees officially designated Dr. Blasingame to that position and Dr. Ernest B. Howard to the position of Assistant Executive Vice-President at its meeting immediately following the adjournment of the House of Delegates.

Since Jan. 1 Dr. Blasingame has recommended and the Board has approved many changes in the headquarters office administrative set-up which has resulted in smooth functioning and efficient operation of the various departments. Additional recommendations are being readied for consideration by the Board of Trustees and will be reported at a later date.

PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION

The Journal of the American Medical Association

Although a survey was not made during 1958 the acceptance of The Journal as a source of information on scientific medicine and medical organizational events seems to be increasing. Surveys during the past eight years have revealed the coverage broadly desired by readers. These wishes have been met as circumstances have permitted and will be respected in the future. While an adequate résumé is difficult to prepare within the limits seemingly appropriate for an annual report to the House of Delegates, some indication of the activities for the past year can be gained by focusing attention on a few highlights.

The number of editorial pages published between July 1, 1957, and June 30, 1958, was 6,899. Advertising pages exceeded 6,500. During this time almost 700 manuscripts appeared in The Journal. Several special issues appeared which featured conventions, state board data, postgraduate courses, internships and residencies, and medical education.

An unique service provided through The Journal in 1958 was the issuance of three special numbers, one in February, one in March, and one in June. They were entitled:

"A Guide to the Evaluation of Permanent Impairment of the Extremities of the Back"
"Federal Income Tax Guide for Physicians"
"Principles of Medical Ethics: Opinions and Reports of the Judicial Council"

The response was sufficient to justify the hope that this practice can be followed selectively in the future as the need arises.

Seventy-Fifth Anniversary.—The July 12 issue of The Journal commemorated its 75th birthday. Developing the theme "Partners in Progress" contributors representing varying walks of life joined hands editorially to emphasize how medicine serves the community and in turn how other phases of community life affect medicine. This issue of The Journal was widely quoted and reprints of the articles are reported to be widely circulated. Some articles were reproduced in other periodicals, for example, John Steinbeck's story of the dedication of a boy and his family to obtaining a medical degree. Unforunately not all phases of community life could be represented, but reports seem to indicate that this rather unusual approach for an anniversary issue of a medical journal reached the objective in mind for it.

Medicine at Work.—There appears to be continued growth in readership of the section entitled Medicine at Work. Begun in 1956, this department attempts to document in highly readable form the significance of physician activities as they relate to nonmedical groups and individuals cooperatively engaged in health betterment along specific lines. During the past year (July 1, 1957, to June 30, 1958) Medicine at Work has explored "in depth" such varied subjects as aging, disaster preparedness, world medicine, rehabilitation, serendipity, grievance committees, and hospital care. Over 600 tear-sheets of these articles have been sent, on request, to physicians in private practice, armed forces, government agencies, hospitals, local health departments, medical centers, private research laboratories, and universities. The requests have come from 32 states and 7 foreign countries. Summaries of the articles have appeared in editorial and news columns of more than 400 daily and weekly newspapers. Digests or complete reproductions have been published in *Reader's Digest, Catholic Digest, Changing Times, Farm Journal, Best Articles & Stories, Today's Health, Trustee, Biochemic Review, Science News Letter,* and several score other lay, medical, and allied scientific journals. One Medicine at Work article (on religion and medicine) drew an audience of additional millions this year when the *Reader's Digest* translated an earlier condensation of it for five international editions and encouraged a team of English writers to adapt the article for *Digest* readers in Britain (crediting The Journal as the basic source). Because this total response to Medicine at Work now clearly illustrates the filling of a need in medical journalism, Mr. Milton Golin, who has handled this department, is assigned the task of adapting that feature-story format into a distinctive new section with the help of two new staff members. This section will include, in addition to the "in depth" feature, a planned layout of briefer and more varied items about activities more precisely within the medical profession and the A. M. A. organization. These items of significance will be reported in an interpretive tone similar to that of the Medicine at Work articles.

Medical News.—Eighteen hundred items were published in the Medical News section of THE JOURNAL during the year ended June 30, 1958. These reports originated from 47 states, Alaska, the District of Columbia, the Hawaiian Islands, Guam, the Canal Zone, Puerto Rico, and 72 foreign countries. Subjects ranged from medical conferences to licensure, and also included news about construction and expansion of hospitals and other health facilities, personnel changes, medical association elections, research studies, fellowships and awards, personals, public health, medical schools, clinics, and health surveys. During the year 295 JOURNAL pages were devoted to these news items and to 27 photographs and two maps relating to the items. In the same period, 3,922 *obituary notices* were published.

Questions and Answers.—More than 2,000 questions relating to practical medical problems were received in THE JOURNAL office. Answers to questions were prepared by 900 consultants recognized as competent authorities by the majority of the medical profession. Incidentally, the opinions offered as answers in the Questions and Answers section of THE JOURNAL are never intended to represent those of the American Medical Association or any other medical organization.

During the same 12-month period 754 Questions and Answers were published in THE JOURNAL. In addition, 72 comments concerning previous questions were also published utilizing a total of 292 pages of JOURNAL space. While there were 20% less Questions and Answers published than during the preceding year, 20% more page space was devoted to that section. As during the preceding years the predominant requests for clinical information were in the fields of dermatology and allergy. However, paralleling the number of questions concerning dermatology and allergy were inquiries concerning nutrition in medical practice. The number of questions on diet as a preventive and therapeutic tool would certainly seem to indicate an intense interest in this subject matter by the practicing physician. Based on the type of questions received after the previously mentioned subjects, expressed interest in the descending order seems to be in the field of industrial medicine, gastroenterology, obstetrics and gynecology, urology (primarily males), clinical pathology, endocrinology, and pharmacology. In every category there are always questions concerning the rare lesion or symptom seen for the first time by the inquiring physician.

In order to assure both the consultant and the eventual reader of the Question and Answer that the question comes from a reputable physician, therefore keeping the tenure of the question both medically reasonable and at the same time avoiding the propagation of "quack" information, every letter to THE JOURNAL must contain the writer's name and address before it can be considered. When, however, the inquiring physician requests his name be omitted, his request is meticulously observed. The consultant always remains unidentified. This not only allows the authority who answers the question to be completely unbiased, but at the same time it prevents his entering into profuse correspondence which would more than tax his already overworked schedule.

Medical Literature Abstracts.—THE JOURNAL first established an abstract service in 1899 under the departmental title "Current Medical Literature." This title was changed in 1954 to "Medical Literature Abstracts." Approximately 2,600 articles are abstracted each year; and 80 pages of abstracts as an average are published each month. These are taken from journals that may be published weekly, monthly, or even less frequently, so probably not more than 80 different publications are represented in one month. However, over a period of four months abstracts are made from as many as 250 different publications. Approximately two-thirds of the abstracts appearing in THE JOURNAL are from foreign language journals and one-third from publications of the British Commonwealth.

Specialty Journals

The analysis of the Specialty Journals has about run its course for any large scale improvement. Extensive changes in the department operation, and in re-designing the journals, have been accomplished. Improvement is, of course, a never-ending management responsibility involving the elimination of details which serve no useful purpose in the mechanical processing of articles. This goes on.

The Editorial Boards of several Specialty Journals are re-examining editorial policy. The *Archives of Internal Medicine,* for example, has become more departmentalized. These departments include Editorials, Reviews of Internal Medicine, Treatment in Internal Medicine, Evolution of Modern Medicine, Contributions of Basic Science to Modern Medicine, and greater emphasis on book reviews. The *Journal of Diseases of Children* has shifted its emphasis from a journal of abstracts to one of original articles and case studies. Its emphasis is on the academic side of the specialty. With more of the Editorial Boards meeting for the express purpose of re-examining editorial policy, it is anticipated that more of them will reveal definite planning as opposed to complete reliance on contributions. In every case, quality is the goal of editorial policy.

The *Archives of Industrial Health* has taken two important steps in becoming of greater service to more physicians in the various branches of Industrial Health. The American Academy of Occupational Medicine now designates the *Archives of Industrial Health* as its official organ. During the course of the year, the *Archives* also established an unofficial association with the Industrial Hygiene Foundation. In each instance, the papers presented at the Annual Meetings of these associations will be published as symposiums. The May, 1958, issue of the *Archives* carried the complete program of the Industrial Hygiene Foundation. The papers from the American Academy of Occupational Medicine will appear in the August, 1958, number.

There has been a heavy increase in the material published through this year. A supplement to the *Journal of Diseases of Children* was published in January on the subject, "The Prevention of Mental Retardation." A "Symposium on Visual Mechanisms" was published as a supplement to the *Archives of Ophthalmology* in October. The *Archives of Internal Medicine,* February issue, was twice its normal size as a result of publishing a collection of papers dedicated to Dr. William B. Castle. The *Archives of Pathology,* October issue, also was an enlarged dedicatory number to Dr. Shields Warren. At the beginning of the year the *Archives of Neurology and Psychiatry* was increased in size from 128 pages to 160 and the *Archives of Ophthalmology* from 192 pages to 208.

During the first eight months of 1958 the Specialty Journals published 1,078 original articles, 27 progress reports or general reviews, 132 case reports or clinical reports, 10 illustrated articles or scientific exhibits, and 9 editorials, or a total of 1,256 articles. The total of unpublished articles for all Specialty Journals is 845. It is anticipated that 625 more papers, covering all categories, will be published during the remainder of the year. The number of articles published in 1958 represents an increase of approximately 10% over the volume of scientific papers published during the first eight months of 1957. For this eight-month period there were 7.2% more pages of editorial matter in 1958 than in 1957.

One really new development in the Specialty Journals Department during 1958 is a new journal which is to be distributed to A. M. A. members as a benefit of membership. The A. M. A. Annual Convention will be the main source of its content. The title *Medicorama* has been selected because it appropriately expresses the vastness of the A. M. A. Convention and its total coverage of all medical branches.

The Section Secretaries make up the Board of Directing Editors. With this new journal as its publication outlet, the Directing Editors can plan at least in part the program for the Annual Meeting with a view to satisfying the needs of the A. M. A. total membership for literature on current medical problems.

Medicorama is a Specialty Journal in a different sense. It is to emphasize the interrelationship of the several sections of medicine in the discussion of a medical problem. It will, therefore, be valuable reading to all physicians rather than to one specialty. The contents of each issue of *Medicorama* will be planned. The conferences, panel discussions, and symposiums, individual papers, scientific exhibits and film reviews, all dealing with a common subject, will be brought together in one issue. In effect, each number of this publication will be a monograph which, for most practical purposes, will collate, coordinate, and integrate fragments of information for its readers.

The schedule for this journal calls for bi-monthly publication following the 1959 Annual Meeting, with the prospect of becoming a monthly publication following the 1960 convention. Two pilot issues are scheduled from the 1958 meeting in San Francisco. The first number, covering the subject, "Diagnostic Radiology," will be distributed February, 1959. The subjects, "Atherosclerosis" and "Psychiatric Emergencies in General Practice" will be reported in a May, 1959, number.

Despite this accelerated program, the Specialty Journals, as a group, remains on a desirable financial basis. The trend in the sale of advertising space is upward. There is evidence of an awakened interest in the possibility these journals offer. The editorial quality is ever improving, and all but two of these nine journals have comparable or top circulation among the specialty publications in their field.

Quarterly Cumulative Index Medicus

As usual two volumes of the Quarterly Cumulative Index Medicus have been printed during this fiscal year, Volume 57 in October, 1957, and Volume 58 in April, 1958. The former covers literature received from January through June, 1955, and the latter from July through December of that year. This still leaves the Index two years behind the previous publication schedule. The situation has shown little improvement in the past year for the same reasons that were mentioned in earlier reports. As of June 30, Volume 59 (January-June 1956) was in press and nearing the final stages of production. The cards for Volume 60 (July-December 1956) were practically ready to be processed. A system of prechecking copy has been devised to speed the work of editing this volume, and streamlining certain steps in revising cards and proofreading should also help.

The periodicals indexed have been divided into two groups, one including English-language journals and the other foreign-language publications. The former are processed as they are received and copy covering them is usually in file within two or three weeks. Part of the copy for the book section is also prepared currently. These are entries for books received for review and listed in THE JOURNAL of the American Medical Association. The rest of the titles are collected from book lists, catalogs, advertisements, and other sources just before each volume goes to press.

The Index remains fairly constant in size though 16 periodicals were added in Volume 57, and 10 in Volume 58. Volume 57 covered 32,175 articles and required 113,000 separate entries; Volume 58 included 31,213 titles with 111,300 entries. There were 1,346 books listed in Volume 57, and 1,318 in Volume 58.

Of the regular complement of 28 employees, 11 have left during the year, and 3 have taken long leaves of absence. In making replacements, the aim has been to maintain quality requirements even though the employment market for this type of work is still tight.

Standard Nomenclature of Diseases and Operations

In recent years, there have been notable advances in the knowledge of diseases and operations. Much of the information acquired has resulted from research, observations, and experimental data. Correct and acceptable terminology is being more and more emphasized. It is from comparable research that pathways are opened for improved methods of diagnoses, treatment, and care of the sick and injured. Results of the Standard Nomenclature Committees in their united effort to encourage the use of acceptable terminology have been far reaching, and their efforts will continue to be recognized as long as they continue to function.

Great strides have been made toward the completion of the Fifth Edition of the Nomenclature. Our Committees consider correct and acceptable terminology to be one of the paramount aids to education, communications, and research in the health program and are endeavoring to reevaluate their particular sections of the nomenclature with this in mind.

The editors are working cooperatively with all committees. The Dental Committee has had two meetings, and its section is ready for typing in final form. The Psychiatric Section has been presented for final approval. The Toxicology Committee met in Washington, D. C., on April 16, 1958, and another meeting is planned for September, 1958. As knowledge concerning toxicology has accumulated very rapidly in the past 10 years, it will be necessary to add, delete, and change this section extensively. The Respiratory, Ophthalmology, Urology, Dermatology, Cardiology, Hematology, and Female Genital Committees have all presented additional data. As the various sections are completed, they will be typed and mailed to each member of the respective committee for his final evaluation. It is anticipated that all material will be ready for publication by December 31, 1959.

The correspondence has continued to increase during the past year. Over 5,000 queries have been answered by the editors, and over 3,000 letters have come to the Standard Nomenclature Office, relating to specific and special Nomenclature problems, queries relative to recommended installation procedures, use of the Nomenclature in doctors' offices, medical clinics, pathology departments, tumor clinics, for filing medical literature, slides, and medical motion pictures.

The American Medical Association has conducted 12 Standard Nomenclature Institutes to date: Four at headquarters in Chicago, one in New York City, Atlantic City, N. J., Roanoke, Va., Indianapolis, Atlanta, Ga., Tulsa, Okla., San Francisco, and Boston. Approximately 1,400 students have been accommodated. These Institutes are tuition-free and are offered as a service to anyone using or interested in installing the Nomenclature. Nurses, doctors' secretaries, clinic clerks, statisticians, medical record clerks, technicians, and librarians, administrators, clinic directors, and physicians have attended. The teaching is under the direction of the editors. The program consists of elementary anatomy as it pertains to the topography of the Nomenclature and sound principles basic to the Nomenclature as well as recommended methods of installation and maintenance. Twenty-five states, Canada, and the territory of Hawaii have been represented. The Institutes are planned through 1961. In 1959, educational programs will be conducted in Tennessee, Washington state, and New York.

The Standard Nomenclature editors are working closely with the Bureau of Medical Economic Research on its project "Totality of Physicians' Service in Hospitals." It is anticipated that a satisfactory Clinical Statistical Classification may be devised from this project which will meet the needs of researchers throughout the country.

All articles published in The Journal of the American Medical Association are coded according to Standard Nomenlature and classified by disease, operation, and author. A special file is maintained by Standard Nomenclature personnel for articles on various drugs.

Standard Nomenclature exhibits have been shown at national meetings in Milwaukee, Atlantic City, and San Francisco. These exhibits acquaint physicians and lay personnel with the organization of the Nomenclature, how the committees work, and emphasizes instructions in use of the Nomenclature.

During the past year, in addition to the regularly sponsored Institutes, the Nomenclature Department has participated in state Institutes in Iowa and Indiana and in a two-day Standard Nomenclature program sponsored by the School of Hospital Administration of the Committee of the Hospitals of Quebec in Ottawa, Ontario. All lectures given at this Institute were translated into French and distributed to the students.

In addition to the regular routine work on the Nomenclature, a Second Supplement was compiled and printed in February, 1958. This supplement is now being distributed from headquarters, on request. A list of acceptable abbreviations is being compiled and is expected to be ready for distribution within the next year. A trial correspondence course in Standard Nomenclature is being conducted. Three students are participating in the pilot study.

In the interim between editions, it is necessary to add, condense, and completely rewrite certain sections of the Nomenclature; but it is the objective of the editors to accommodate the new knowledge without sacrificing essential data or materially increasing the size of the Nomenclature volume.

Today's Health

In the 12 months covered by this report *Today's Health* has undergone many changes which have resulted in an improved publication.

In July, 1957, *Today's Health* was given authorization from the Board of Trustees to undertake a complete reorganization of the *Today's Health* headquarters staff. This was a direct result of a proposal made in November, 1956, and based on the premise that "there is nothing wrong with *Today's Health* that cannot be corrected by following professional magazine publishing practice."

From an administrative standpoint, the major organizational changes took place in the Editorial Department. *Today's Health* was fortunate to secure the services of Mr. James M. Liston, former Special Features Editor of *Better Homes & Gardens,* as Editor. Mr. Liston is the first full-time editor the magazine has ever had, and he brought with him a thorough understanding of consumer magazine publishing. Shortly thereafter, two new Associate Editors, an Art Director, and a Production Coordinator were added to the editorial staff; the magazine was placed in the hands of one of the country's leading magazine artists who was commissioned to design the new *Today's Health;* a new technique of pictorial journalism was introduced along with a bright, cogent style designed to deliver the facts with a minimum of effort for today's busy reader; special editorial features were published that show people how to enjoy better health through better living; and, of course, *Today's Health* continued to build a reputation for publishing the definitive story in order to maintain reader confidence and acceptance.

In addition to a complete restyling of the format and a broadened editorial approach, one of the most significant changes was the expansion of the subtitle to read "Published by the American Medical Association FOR THE AMERICAN FAMILY." This clearly defines the editorial purpose of the magazine as well as the readership.

The new *Today's Health* was introduced to the general public with the May, 1958, issue. The reception was spontaneous and excellent as reflected by "fan mail," increased circulation, and increased advertising. *Today's Health* is being quoted more than ever before, and article reprints are at an all-time high.

It is an established fact that advertising revenue is the lifeblood of most magazines, and that is particularly true of *Today's Health.*

During the period covered by this report, the advertising sales staff was expanded by the addition of a third man in the New York office and commisioned representation on the West Coast and in the Southern states. Adequate office facilities were secured in New York and certain organizational changes were made in the headquarters office. All of this, together with intensified sales promotion and merchandising services and a "new" magazine, resulted in a substantial revenue gain over the previous year. Advertising renewals and the establishment of new advertising accounts point to an extremely bright future.

The addition of a Production Coordinator to the *Today's Health* staff has been particularly helpful to the advertising department. New production controls and procedures have been established, and liaison between the Advertising and Editorial Departments is excellent.

In August, 1957, a *Today's Health* Advertising Review Committee was appointed. Miss Evelyn J. Dyba was appointed advertising Copy Supervisor. Operating on a set of established Principles this committee has been very valuable to all phases of the magazine's operation.

AMA News

In accordance with various actions taken by the House of Delegates regarding a mechanism of communication for disseminating medicine's message to members of the American Medical Association and others in the health field, the Board of Trustees approved the establishment of a biweekly newspaper—*The AMA News.*

The newspaper will be edited with the idea of keeping the physician informed in the medicoeconomic field, concentrating on news not now carried in the A. M. A. journals.

The editor of *The AMA News* arrived at Chicago headquarters June 1, so actually this report covers the period from June 1, 1958, to June 30, 1958.

During June a printer was engaged and plans were completed to publish a pilot issue Aug. 11. First issue of *The AMA News* was distributed Sept. 22.

A format of the front page appeared on page three of the June 23 issue of the *Daily Bulletin* during the San Francisco convention.

LIBRARY

The Library has had another busy year. Altogether 3,175 letters involving reference work were received. In response, 2,170 package libraries were prepared for borrowers and 1,000 other requests were filled. These required a search of the literature, preparation of lists of books and articles, and location of various information. In addition, numbers of unrecorded questions were answered by phone and in person. The reference department has given special attention to supplying lists of recent references from the files for future volumes of the Quarterly Cumulative Index Medicus, and also to include reprints of this material in package libraries.

The Periodical Lending Service has recorded 9,900 loans in this period, 3,410 for package libraries. There were 2,515 intramural loans aside from the usual circulation of journals when first received.

A special effort has been made to increase the number of reprints, tear sheets, and other material in the package library files so that these may be substituted for complete journals in loaning material. This cuts postal charges and also the loss of periodicals which usually have to be replaced. Considerable use has also been made of Thermofax copies of shorter articles and those in repeated demand. Since there have been numerous requests from physicians and librarians for information on the organization of medical libraries in county societies, hospitals and clinics and on medical careers, attention has also been given to acquiring material on these two popular subjects outside the clinical field.

There were 292 book titles added to the catalog this year and 177 withdrawn, leaving a total of 4,320 including bound serials. As stated before, the aim is to keep the book collection current and useful without exceeding 5,000 volumes.

At the end of last December the Library was receiving 1,600 periodicals, almost evenly divided between English-language and foreign-language publications. During the report period 150 titles not previously received in the Library were noted, 60 of them entirely new publications. Of the total, 29 were boxed in the regular files and 51 referred to the sample collection. The rest were distributed to other departments and libraries.

The Library, as always, has recorded the books sent for review in THE JOURNAL of the American Medical Association and prepared the lists for the Books Received column. 1,477 publications were handled this year, many of them assigned for review. The details of this operation are also part of the Library routine.

Another regular duty of the Library is the compilation of an index to each of the three volumes of THE JOURNAL of the American Medical Association that appear annually.

Five members of the Library staff attended the refresher courses in medical library science which were offered by the Medical Library Association just before its annual meeting in June. These sessions proved most profitable to all whom it was possible to send.

LAW DEPARTMENT

This report covers the activities of the Law Department from July 1, 1957, to June 30, 1958. During this period the Department has continued to operate as the coordinating agency for the legal activities of the Association. In addition the Department provided staff assistance for the Judicial Council, the Committee on Legislation, the Council on Constitution and Bylaws, the Committee on Medicolegal Problems, and numerous other temporary committees.

Under the direction of the Secretary and General Manager and the Executive Vice-President, the Department has acted as legal adviser to the Board of Trustees and the House of Delegates, as well as to the officers and executive staff of the Association. This work has involved a variety of legal problems dealing with contracts, taxes, leases, copyrights, trade-marks, antitrust law, libel, slander, and insurance.

In association with outside legal counsel, members of the staff of the Law Department have provided advice in these matters and in handling four court cases to which the American Medical Association was a party.

Liaison Activities

Inter-Association Work.—Each of the attorneys on the staff of the Department continued to maintain liaison with one or more of the Association's permanent councils and committees by attending meetings, assisting in the answering of correspondence, reviewing prospective programs and giving oral and written legal advice. In addition, members of the staff have attended meetings and have provided legal and administrative assistance to numerous temporary committees and subcommittees of the Association. Examples of these special committees staffed by the Director or members of the staff include:

American Medical Association-American Bar Association Liaison Committee
American Medical Association-American Hospital Association Liaison Committee
Committee to Review the Heller Management Survey Report
American Medical Association-American Bar Association Committee on Narcotic Addiction
American Medical Association-American Hospital Association Joint Committee on Medical Professional Liability
Committee to Review Controversy between the Medical College of Georgia and the County and State Medical Societies

Medical Societies and Individual Physicians.—The Department has, through correspondence and personal visits, maintained contact with the executive secretaries and the legal counsel for state and county medical societies. Representatives of the Department have on request spoken at, or presented programs on medical-legal subjects at, state and local medical meetings and at joint medical-legal conferences.

The staff of the Department has also staffed and explained exhibits on Medical Professional Liability and the Drinking Driver at state and county medical meetings. These exhibits have been shown on 22 occasions.

In an effort to keep the legal counsel and executive secretaries of the medical societies advised of current legal activities, court decisions, and trends affecting medical societies and individual physicians, the Law Department initiated a periodical newsletter identified as "The Citation." The first issue was published on May 9, 1958.

Although a statistical record has not been kept of the number of letters received and answered, there is no doubt that several thousand inquiries were handled by the Department during the period of this report. These letters from individual physicians, attorneys, medical societies, and outside organizations deal with a wide variety of problems in the medical-legal field.

In the opinion of the Department, one of the most significant and successful activities during the year was the Second National Conference for Attorneys and Executive Secretaries of state and county medical societies. The two-day meeting which was held on May 9-10 was attended by 142 attorneys and executive secretaries. During the meeting 16 speakers presented papers and answered questions on the following subjects:

Legal Aspects of Medical Practice Through "Third-Party" Mechanisms
Medical Professional Liability
Libel, Slander, and Privacy in Medicine
Legislation and Lobbying Practices of State Medical Societies
Tax Advantages of Corporations and Unincorporated Associations

Medical-Legal Relations.—During the period of the report the Department has encouraged and participated in joint medical-legal conferences at the national, state, and local levels. Assistance has been provided in the negotiation of written codes of understanding between physicians and attorneys. Most significant in this regard was the assistance rendered to the American Medical Association–American Bar Association Liaison Committee in the drafting of a national Inter-Professional Code which was approved by the House of Delegates of the American Medical Association at its meeting in June. It is anticipated that the same Code will be endorsed by the House of Delegates of the American Bar Association at its meeting in August, 1958.

During the year, the Director of the Law Department was invited and agreed to participate as a member of the National Advisory Council of the Law-Medicine Research Institute of Boston University. The aim of the Law-Medicine Research Institute will be to bring together leading authorities in the fields of law, medicine, the behavioral sciences, and related areas to work on problems of mutual concern.

National Association.—Members of the staff attended or participated on the programs of the following national associations:

- International Association of Insurance Counsel
- Association of American Railroads
- Radiological Society of North America
- American Society of Clinical Pathologists and College of American Pathologists
- Northwestern University Traffic Institute
- International Association of Research Anesthesiologists
- American Standards Association
- Association of Medical Secretaries and Assistants
- American Association of Medical Clinics
- National Safety Council
- American Veterinary Medical Association
- National Association of Defense Attorneys
- National Association of Claimants Compensation Attorneys
- American Bar Association

Preparation or Review of Published Material

The Department has continued to work closely with the editors and the staffs of THE JOURNAL, specialty journals, and *Today's Health* in preparing special articles, book reviews, and editorials. Assistance has also been provided in reviewing material submitted from other sources with possible legal implications.

The following list indicated the material prepared by the Department and the dates of publication:

Professional Liability	
Profesional Liability Involving Physicians in Federal Government Service	Sept. 28, 1957
Analysis of Professional Liability Claims and Suits	Oct. 5, 1957
Medical Defense in the United Kingdom	April 26, 1958
Review of Medical Professional Liability Claims and Suits	May 10, 1958
Medicolegal Forms	
Consent to Operations and Other Procedures	Sept. 7, 1957
Patient's Right to Privacy	Sept. 14, 1957
Confidential Communications and Records	Sept. 21, 1957
Artificial Insemination	Sept. 28, 1957
The Physician-Patient Relationship	Oct. 5. 1957
Autopsy	Oct. 12, 1957
Miscellaneous	
Complaint Against a Physician Submitted to a Medical Society—Basis for Libel Action by the Physician	Sept. 21, 1957
Medical-Legal Problems and Their Solutions	Oct. 12, 1957
Use of Paternity Tests in Criminal Proceedings for Nonsupport	Dec. 28, 1957
The Sherman Act and the Practice of Medicine	Jan. 4, 1958
Fraudulent Concealment of a Patient's Cause of Action	Jan. 11, 1958
Use of Pooled Plasma as a Medicolegal Hazard	Jan. 18, 1958
Salga v. Stanford University Hospital (Gerbode Case)	Jan. 25, 1958
Medicolegal Aspects of Sterilization, Artificial Insemination and Abortion	Feb. 8, 1958
Opinions of the Judicial Council	Feb. 15, 1958
Ownership of and Access to Hospital Records	Feb. 15, 1958
Physical Examination of Plaintiff on Motion of Defendant	Feb. 22, 1958
Chemical Tests for Intoxication—"Implied Consent" Laws	June 14, 1958

The most significant contribution of the Department in this regard was the preparation and publication of the following three items:

(a) **"Medicolegal Forms with Legal Analysis."**—This booklet of 111 pages includes 42 suggested forms, explanatory text material, and case citations dealing with: Consent to Operations and Other Procedures; Patient's Right to Privacy; Confidential Communications and Records; Artificial Insemination; The Physician-Patient Relationship and Autopsies. To date these booklets have been distributed to members of the American Medical Association without charge and to other interested parties and organizations at one dollar a copy. Thus far 7,700 booklets have been distributed.

(b) **Special Edition of THE JOURNAL** dated March 1, 1958, entitled "Federal Income Tax Guide for Physicians." This item was distributed as a special edition of THE JOURNAL to all members of the Association.

(c) **Special Edition of THE JOURNAL** dated June 7, 1958, entitled "Opinions and Reports of the Judicial Council." This item was distributed as a special edition of THE JOURNAL to all members of the Association.

Special Projects of Medicolegal Significance

During the year the Department planned, developed, and directed a number of projects of substantial importance to the medical profession and the Association. Some of the more important ones were:

Medicolegal Film Series.—The Department assisted in the preparation of the script and advised in the production of a medicolegal film dealing with traumatic neurosis entitled "The Man Who Didn't Walk." This film was previewed at the Association's annual meeting in San Francisco in June. It was the third in a series of six to be prepared jointly by the American Medical Association and the American Bar Association with the financial assistance of the Wm. S. Merrell Company of Cincinnati.

Student Medicolegal Program.—Members of the staff participated in and helped to organize a Medicolegal Day at Harvard University. Students of medical and law schools in the Boston area were invited to attend this meeting and participate in a discussion of medicolegal problems. The program was jointly sponsored by the Student American Medical Association and the Junior Bar Association. The medical and law schools in the Omaha, Neb., area are planning a similar program for their medical and law students this coming spring.

Proceedings Before Federal Communications Commission.—In October the Department prepared and filed a brief in three Federal Communications Commission proceedings requesting that additional radio communication channels be made available to physicians for (1) day-to-day use to receive and answer emergency calls; (2) undergraduate and postgraduate medical training; and (3) use in a disaster or medical emergency. The Department has also assisted in staffing the Radio Communications Committee.

Medical Professional Liability.—The Department continued its study of medical professional liability. At its request a Joint Committee was established by the American Medical Association and the American Hospital Association in an effort to study in-hospital medical professional liability problems and to devise a workable prevention program.

All necessary preliminary work has been completed for an opinion survey of attorneys concerning this subject. A questionnaire has been devised and perfected on the basis of personal interviews with numerous attorneys located in various parts of the United States.

Medicolegal Abstracts

A continuing project of the Law Department has been the preparation of abstracts of court decisions in the medicolegal field for publication in The Journal. The preparation of Volume VI of the permanent bound volumes of abstracted cases has been initiated. References to a few of the cases abstracted and published during the period covered by this report are given below.

Licensure.—The Court of Appeals of Kentucky (Bandeen v. Howard, 299 S. W. (2) 249) upheld the revocation of an osteopath's license on the grounds that he used medicines of doubtful value and made unjustified promises of cure. It was shown that he had utilized "Koch Shots" for cancer treatments. The Court of Civil Appeals of Texas (Wilson v. State Board of Naturopathic Examiners, 298 S. W. (2) 946) upheld the constitutionality of the Texas Naturopathic Act. Both the District Court of Appeal of California (Furnish v. Board of Medical Examiners, 308 P (2) 924) and the Supreme Court of Washington (In re Kindischi, 319 P (2) 824) upheld the revocation of a license to practice medicine for violation of the income tax laws on the ground that such violations involved moral turpitude.

Medical Professional Liability.—Leaving a foreign body in a patient's abdomen is usually sufficient to raise an inference of negligence under the doctrine of res ipsa loquitur. The Supreme Court of California, however (Leonard v. Watsonville Community Hospital, 305 P. (2) 36) held that this inference could be dispelled by the testimony of the defendants given as adverse witnesses in response to the plaintiff's subpoena. The Court of Civil Appeals of Texas (Sims v. Auringer, 301 S. W. (2) 286) held that the execution of a release to the person causing an automobile accident also operated as a release of a physician charged with malpractice in the care of the injuries caused by the accident. The Court of Appeals of Georgia (Robinson v. Campbell, 97 S. E. (2) 544) held that a physician is not liable for injuries to a patient with defective eyesight who is hurt trying to climb out of an examination chair unassisted and in an unfamiliar office. The Supreme Court of California (Salgo v. Leland Stanford Jr. University Board of Trustees, et al, 317 P. (2) 170) held that aortography and its results, because it is a relatively new diagnostic procedure, is not a matter of common knowledge among laymen and it cannot be said that it is a matter of common knowledge that injury results only where there has been negligence in its use. Since it is a matter outside the realm of the layman's experience, it cannot be the basis for the application of the doctrine of res ipsa loquitur.

Consent.—The Supreme Court of Oklahoma (In re Kyle's Autopsy, 309 P. (2) 1070) refused to uphold an autopsy permission given by the sisters of the decedent when the surviving spouse refused such permission. The Supreme Court of Florida (Stauf v. Holden, 94 So. (2) 361) held that a trial court should not have charged the jury that "In a case against a physician for malpractice, the professional character and reputation of the physician is the most important matter at stake, and hence he should not be condemned by evidence that does not point to his negligence." The United States Court of Appeals for the Fifth Circuit (Lester v. Aetna Casualty and Surety Company, 240 F (2) 676) held that the consent of a wife to electroshock treatments for her husband was sufficient where it appeared that the husband's condition was such that it would be unwise and unsafe to require him to undergo the strain of discussing and considering the possible hazards involved in such treatments.

Hospital Liability.—The Supreme Court of Iowa (Wittmer v. Letts, 80 N. W. (2) 561) held that the operation of a county hospital is a proprietary function, at least so far as a pay patient is concerned, and should be considered in the same light as a private hospital which is liable in tort for injuries to pay patients injured through the negligence of its employees. The Supreme Court of Nevada (Hughey v. Washoe County, 306 P (2) 1115) also upheld that liability of a county hospital. The Court of Appeals of Tennessee, however (McMahon v. Baroness Erlanger Hospital, 306 S. W. (2) 41), held that the rule of governmental immunity protects a governmental hospital from suit for damages because of the negligent acts of its employees.

The Court of Appeals of Tennessee (Rural Education Association v. Bush, 298 S. W. (2) 761) held that a hospital was liable for the negligence of a nurse who, through an inadequate sponge count, permitted the leaving of a sponge in a patient's body during surgery. The Court held the counting of sponges was not a medical act. In considering whether or not a hospital should be liable for the negligent acts of its nurses, the Court of Appeals of New York (Bing v. Thunig, 143 N. E. (2) 3) held that the test should be "Was the person who committed the negligent injury-producing act one of its employees and, if he was, was he acting within the scope of his employment?"

Privileged and Confidential Communications.—The Supreme Judicial Court of Maine (Dunbar v. Greenlaw, 128 A. (2) 218) held that a physician's certificate of insanity in a detention hearing is privileged and cannot be the basis for a libel action. The Court of Appeals of New York (People v. Decina, 138 N. E. (2) 799) held that the presence of a police guard at the hospital door who was able to see and hear all that took place between the patient and his physician did not destroy the physician-patient privilege created by the New York law. The physician should not have been permitted to testify.

The Supreme Court of Minnesota (Nelson v. Ackermann, 83 N. W. (2) 500) held that when a physician-patient privilege is asserted by a party to an action seeking recovery for personal injuries and the nature and extent of the injuries are involved, it is not error to permit fair comment to the jury by the adverse party on his inability to examine such attending physician concerning his examination and treatment of the patient.

Miscellaneous.—The Supreme Court of Washington (Young v. Liddington, 309 P (2) 761) held that a hospital record containing a medical opinion as to causation, which is not the result of an observed act, condition, or event, is not admissible in evidence.

The Supreme Court of Minnesota (Maetzold v. Walgreen Company, 83 N. W. (2) 233) held that the privileged communications statute of that state did not disqualify or preclude an attending physician from giving expert medical testimony based on a hypothetical question which excludes all knowledge or information gained by the doctor in examining or treating the patient.

The Supreme Court of North Carolina (Sherin v. Lloyd, 98 S. E. (2) 508) held that in an action for damages, resulting from negligent breach of duty, the statute of limitations begins to run from the time the wrongful act or omission complained of was committed without regard to the time when the harmful consequences are discovered. The United States Court of Appeals for the sixth circuit (Merck and Company v. Kidd, 242 F (2) 592) held that the pharmaceutical company which prepared dried blood plasma is not liable to a person who acquires homologous serum jaundice following the use of the plasma. The presence of the hepatitis virus in the plasma does not render it "filthy" under the Food and Drug Act, nor does it constitute negligence per se.

The Supreme Court of California (People v. Duroncelay, 312 P (2) 690) held that it was not an unreasonable search and seizure to extract blood for testing purposes, even without consent, when the extraction is made in a medically approved manner and incident to the lawful arrest of one who is reasonably believed to have violated the law.

The United States Court of Appeals for the eighth circuit (Rigall v. Washington County Medical Society, et al, 249 F (2) 266) held that the practice of medicine in the state of Arkansas did not constitute trade or commerce within the meaning of the Sherman Act.

COMMITTEE ON MEDICOLEGAL PROBLEMS

This report covers the activities of the *Committee on* Medicolegal Problems for the period from July 1, 1957, to June 30, 1958. During this period, the Committee held two meetings at which reports were received from the following subcommittees: Professional Liability, Chemical Tests for Intoxication, Forensic Pathology, and Forensic Psychiatry.

During the year Dr. Manfred S. Guttmacher of Baltimore, was appointed by the Board of Trustees to replace Dr. Henry A. Davidson of New Jersey.

Medical Professional Liability

The Subcommittee on Medical Professional Liability continued under the Chairmanship of Dr. Joseph F. Sadusk with the substitution of Dr. William M. Nebeker of Salt Lake City to replace Dr. C. G. Heyd of New York as a member.

The group had a meeting in Chicago on March 14, 1958, to work out the final details for a medicolegal program on the subject of medical professional liability which was presented as part of the scientific program of the American Medical Association at the annual meeting in June, 1958. The session was conducted on June 24, at which time the following program was presented.

Standard Provisions of Professional
Liability Insurance Policies
Howard Hassard, *San Francisco*
General Malpractice Insurance Problems
Joseph Linder, New York
Expert Advisory and Witness Panels
Joseph F. Sadusk Jr., Oakland, Calif.
National Medical Professional Liability Trends
C. Joseph Stetler, Chicago

The subcommittee also continued to work with the Law Department in its survey of insuring companies and the legal profession in an effort to develop the proper criteria on which to base a sound and workable claims-prevention program.

Chemical Tests for Intoxication

The Committee with the cooperation of the Law Department continued the presentation at medical and medicolegal meetings of its mock trial demonstration illustrating the introduction of chemical test results in a drunk driving case.

Articles which will comprise the chapters of the manual on Chemical Tests for Intoxication to be published by the Committee are appearing in The Journal of the American Medical Association. It is contemplated that the manual will be completed and distributed in the near future.

During the year the Committee prepared and had published in The Journal two editorials dealing with chemical tests. The first reviewed the bases for the recommendations of the Committee concerning presumptive levels of alcohol content in the blood for chemical test statute purposes. The other outlined the position adopted by the Board of Trustees on the recommendation of the Committee endorsing uniform state legislation patterned after the "implied consent" laws in effect in several states. These laws provide for a presumption to the effect that in applying for and receiving a driver's license a motorist impliedly consents to the taking of a chemical test, if and when arrested for driving while intoxicated.

Medicolegal Film Project

The Committee in cooperation with the Law Department assisted in the preparation of the script and advised in the production of a medicolegal film dealing with traumatic neurosis entitled "The Man Who Didn't Walk." This film was previewed at the Association's annual meeting in San Francisco in June. It was the third in a series of six to be prepared jointly by the American Medical Association and the American Bar Association with the financial assistance of the Wm. S. Merrell Company of Cincinnati.

Coroner-Medical Examiner System

The Committee continued its work during the year in support of the Model Post-Mortem Examinations Act as approved by the National Conference of Commissioners on Uniform State Laws. On Dec. 21, 1957, the Committee published an editorial in The Journal reviewing the progress of the model law during the preceding year.

Distribution of Pamphlets

The Committee continued the distribution of several leaflets and pamphlets by its subcommittees. During this period, 15,050 copies of a leaflet entitled "Test Your A. Q. (Alcohol Quotient)—20 Questions on Alcohol" were distributed. The Committee also continued its cooperative arrangement with the medical schools and distributed approximately 2,400 copies of the pamphlet entitled "Malpractice and the Physician" to graduating medical students. Three hundred requests were filled for the pamphlet "Medicolegal Aspects of Blood Transfusions" and the 1952 report of the Committee dealing with the "Medicolegal Applications of Blood Grouping Tests."

Exhibits on Medical Professional Liability and Chemical Tests for Intoxication

The Committee assisted in the presentation and explanation of the exhibits on chemical tests for intoxication and medical professional liability. These exhibits were shown on 22 occasions.

COMMITTEE ON LEGISLATION

This report covers the period from Sept. 1, 1957, to Aug. 31, 1958. It is necessary to include the months of July and August, 1958, in order to cover the complete activities of the Second Session of the 85th Congress which adjourned on Aug. 24, 1958.

During this period there have been no changes in the composition of the Committee on Legislation. The Committee is presently constituted as follows:

George M. Fister, M.D., *Chairman*
McKinnie L. Phelps, M.D., *Vice Chairman*
C. Byron Blaisdell, M.D.
R. B. Chrisman, Jr., M.D.
Frank C. Coleman, M.D.
Harlan English, M.D.
Frank J. Holroyd, M.D.
J. Lafe Ludwig, M.D.
John E. McDonald, M.D.
D. Olan Meeker, M.D.
George E. Twente, M.D.
Mr. Warren E. Whyte, *Executive Secretary*

During this period the Committee met on four occasions; Jan. 11, 1958, in Chicago; March 29, 1958, in Washington, D. C.; and in an informal meeting of those members present at the annual session of the Association in San Francisco in June, 1958. The Committee had previously met on Aug. 24, 1957, in Chicago. All important legislation of medical interest introduced in the Second Session of the 85th Congress was considered, Association legislative policies and activities were reviewed, and appropriate recommendations were submitted to the Board of Trustees. At the meeting on March 29, the Committee voted to hold its future meetings in Washington, D. C., when Congress is in session, so as to give the members an opportunity to visit their senators and representatives.

Second Session, 85th Congress

Although a final tabulation has not been made, approximately 700 bills of a medical nature or of direct interest to the medical profession were introduced in the 85th Congress; 361 were introduced in the First Session and approximately 340 in the Second Session. The major legislative measures were considered by the Committee on Legislation and recommendations as to the positions of the Association were made to the Board of Trustees.

The number of medical bills introduced in the 85th Congress was an increase of approximately 23% over the 84th Congress, in which 571 bills were introduced. The number in the 84th Congress was in turn a 40% increase over the total in the 83rd Congress.

During the 85th Congress the American Medical Association testified or sent formal statements on 28 important bills. In 19 instances the Association was supporting the legislation or some principle involved. On six occasions the Association was in opposition to the legislation and on four occasions the testimony was solely informational.

The 85th Congress enacted 15 bills of a medical nature. These have either become law or are awaiting the President's signature at the time of this report. Only one of these measures was opposed by the Association. This was H. R. 11414 which provided for annual federal grants of one million dollars to schools of public health. This bill was subsequently amended in the Senate so as to restrict somewhat the use to which these grants could be put. Seven of the bills enacted were actively supported or endorsed by the American Medical Association.

The Forand Bill

Undoubtedly the most important legislation with which the Committee dealt during the period covered by this report was the Forand Bill, H. R. 9467. This measure proposed an amendment to Title II of the Social Security Act so as to provide hospital, surgical, dental and nursing home benefits for the more than twelve million beneficiaries of the Old Age and Survivors Insurance program. It was strenuously opposed at all levels of organized medicine and by the majority of other groups in the health field. At the adjournment of the 85th Congress no action had been taken on the medical aspects of the Forand Bill other than inclusion in the general hearings on Social Security of the Ways and Means Committee of the House of Representatives.

When the Committee on Legislation was informed at its meeting on Aug. 24, 1957, that the Forand Bill was about to be introduced, it recommended to the Board of Trustees that a special committee be set up to study the background of this legislation and to prepare the necessary material and information to be used in opposing this legislation and in testifying before Congress. Dr. Fister was appointed as the Chairman of this committee, later named the Task Force on Social Security Hospitalization Benefits.

Due to the seriousness of the Forand type legislation and its clear-cut threat to the medical profession, the Association established a full-time staff task force to work on this campaign. This group met with the Committee on Legislation at its meetings on Jan. 11 and March 29. The plans and strategy of this special staff operation were placed before the Committee on Legislation in detail and received the endorsement of the Committee on each occasion.

The members of the Committee on Legislation and the state legislative keymen devoted a great deal of time during the period of this report to the Forand campaign. The overall strategy was to contact effectively the 25 members of the House Ways and Means Committee, to which H. R. 9467 had been referred, and to persuade them and other influential Congressional leaders that this legislation was not in the public interest. It was decided that an all-out appeal to the public was not wise at this time as there did not appear to be any public demand for the legislation.

Testimony was given on the Forand Bill by the Association during the Social Security hearings of the Ways and Means Committee in June, 1958. Appearing for the Association were Dr. Leonard W. Larson, Chairman of the Board of Trustees, and Dr. Frank Krusen of Rochester, Minn.

Although this legislation was defeated in the 85th Congress, there can be little doubt that legislation of this type will be the most important legislative measure facing the medical profession and the Committee on Legislation for the next several years. The Committee feels that this type of legislation is a clear-cut and direct threat to the private practice of medicine and it will do everything within its power to insure its defeat.

The Jenkins-Keogh Bills

The Jenkins-Keogh Bills, H. R. 9 and H. R. 10, and similar legislation have been of vital interest to the American Medical Association and the Committee on Legislation since 1951. These measures would provide income tax deferment on amounts put into retirement funds by self-employed persons. After many years of effort, the Jenkins-Keogh Bills came extremely close to enactment in the Second Session of the 85th Congress. H. R. 10 was reported favorably by the House Ways and Means Committee and passed the House of Representatives by an overwhelming voice vote. The bill was referred to the Senate Finance Committee at a very late date and sufficient time did not remain for hearings. However, it was offered as an amendment to a general tax bill from the floor of the Senate. A point of order was raised as to whether it was germane to the measure it sought to amend. It was voted to be not germane by a margin of only 10 votes. It was the general feeling that if Jenkins-Keogh had been brought to a vote in the Senate solely on its merits, it would have passed. The long-standing opposition to Jenkins-Keogh by the Treasury Department and by several congressional leaders appears to be weakening and there is good basis for believing that it will be enacted during the 86th Congress.

Medicare

Another matter of serious concern to the Committee on Legislation during the period of this report were the attempts by certain representatives of the Department of Defense and several congressional leaders to restrict the free choice of civilian physicians and facilities under the Dependents Medical Care Program. The American Medical Association has never endorsed the Medicare program as such but believes that it should be left to the discretion of Congress as to whether such medical care should be given to the dependents of service personnel. The Association has stated, however, that if such a program is to be undertaken, the dependents should have a free choice between military and civilian medical care and health facilities. It is felt that free choice will not only insure a higher standard of medical care for dependents but will also eliminate the need for drafting physicians into the armed forces to care for these dependents.

An attempt was made during the Second Session to restrict this free choice by drastically cutting the appropriation for civilian care of dependents and by placing an absolute ceiling on the amount the Defense Department could spend on such civilian care. The Association and the Committee on Legislation vigorously opposed these restrictions. On two occasions requests for legislative action went out from the members of the Committee to the state legislative keymen and executive secretaries. Congress finally restored the appropriation and eliminated the ceiling on the amount to be spent for civilian care. However, before this was done, the officials of the Department of Defense agreed to restrict the use of civilian physicians and facilities to some extent by administrative regulation.

Other Important Legislative Matters

In addition to those measures mentioned already, the Committee on Legislation dealt with numerous other legislative problems during the period of this report. Included were bills to extend the Hill-Burton construction program and bills to allow loans to be made under this program to those who did not wish to accept grants. The Association testified at the Hill-Burton hearings and made several recommendations for the improvement of the program. Congress finally limited its action to extending the Hill-Burton program and to providing for loans under the program.

During the 85th Congress the Association testified on two occasions concerning veterans legislation. On July 24, 1958, Dr. Russell Roth testified before the House Veterans Affairs Committee concerning the Association's over-all policy on veterans' medical care and our views in general as to the Veterans Administration's medical care program. No definitive action was taken by the 85th Congress in the field of veterans' medical care.

In conjunction with its campaign against Forand-type legislation the Association endorsed several proposals which would serve to help meet the problems of the health care of the aged. On the premise that too little is actually known concerning the problems of the aged, the Association strenuously supported H. R. 9822 which would provide for conferences in each state concerning the health problems of the aged and which would culminate in a White House Conference on Aging in 1961. This bill was enacted. The Association also supported a program of F. H. A. type insured loans for nursing homes. Testimony was presented to both the House and Senate on this subject. The proposal was passed by the Senate but was defeated in the House.

Several bills were introduced in Congress concerning federal grants to medical schools. The Association sent a statement to Congress concerning its position on such grants and representatives of the Association appeared before the House Subcommittee on Health concerning this proposal. No action was taken by Congress on these measures.

Another matter of interest to the Association was the reorganization of the Department of Defense insofar as it would eliminate the position of Assistant Secretary of Defense for Health and Medical Affairs. The Association testified in opposition to the elimination of this important post in our defense establishment. As the reorganization was finally enacted it was left up to the discretion of the Secretary of Defense as to whether one of his assistant secretaries would carry this title. The Association also opposed the elimination of special incentive pay for physicians in the Armed Forces as set up by the Medical Officers Career Incentive Act. The military pay raise legislation originally would have eliminated this special pay for physicians, but as finally enacted this feature of the Career Incentive Act was retained.

State Legislative Keyman Organization

In the latter part of 1956 the Committee on Legislation recommended to the Board of Trustees that a state legislative keyman organization be set up. It was proposed that one physician be appointed in each state as the keyman on national legislative affairs, and that he be formally appointed by the Board of Trustees. The members of the Committee on Legislation were each assigned several states and it was their responsibility to maintain relations with the keymen in their states and to provide information and relay requests for legislative action directly to the keymen. After this proposal was approved by the Board, keymen were nominated and appointed in each state and alternate keymen designated in several states.

During the period covered by this report several requests for legislative action were made through the members of the Committee to the keymen. In addition, the keymen were active in cooperating with the Committee and the staff group throughout the Forand Bill campaign. The response from the physicians throughout the country on Jenkins-Keogh and Medicare was outstanding. The activities of the keymen on the Forand Bill were extensive and had a great deal to do with the Association's success on that legislation during the 85th Congress.

Legislative Activities of the Woman's Auxiliary to the American Medical Association

The program of close cooperation with the Woman's Auxiliary on legislative matters was continued during the period of this report. The Chairman of the Legislative Committee of the Auxiliary, Mrs. Charles L. Goodhand, continued to attend the meetings of the Committee under a policy instituted in February, 1957. The Woman's Auxiliary has completed its own keywoman organization and all requests for legislative action sent to the state legislative keymen were also relayed to the Woman's Auxiliary through their Legislative Committee.

A. M. A. WASHINGTON OFFICE

Relations of Office Staff with Congress and Agencies

Indicative of the expanding interest of Congress in health activities of all sorts, health or medical bills were before 13 of the 19 House committees, and 13 of the 20 Senate committees during the last session. This required the Washington Office to make contacts with staffs and members of 26 committees in addition to covering hearings; in some cases only a few conferences or phone calls sufficed, in others most members of the committee had to be approached repeatedly.

Generally, these contacts were to give staff or committee members a better understanding of the A. M. A. position on certain legislation, but in some instances they were merely to pass on to the committee for its benefit technical health or medical information. Many hours of office time are required to assemble information for Congress, at its request.

In addition to conferences with senators, representatives, and staff people on specific legislation, Washington Office personnel contacted virtually all senators and representatives at their offices or elsewhere in a routine long-range effort to establish and maintain the best possible relationships.

To handle these activities, principal use is made of the four physicians on the Office staff—Director, Acting Director, Associate Director, and Assistant Director, and the staff's three attorneys, all of whom are registered lobbyists.

During the session, the Washington staff covered in person more than 175 man days of open hearings on Capitol Hill and scores of meetings and news conferences in Washington. The objective was to keep in close touch with developments that might affect the A. M. A.'s policies or its legislative operations, and at the same time to obtain prompt, first-hand reports for use in Office publications.

On 18 occasions one or more witnesses testified on behalf of the A. M. A. this year, all of whom were first briefed by the Chicago staff, the Washington Office staff, or both prior to their appearances on Capitol Hill. In addition, 25 letters were sent to committees to apprise them of the A. M. A.'s position on individual bills, and the reasons for the position. In addition, on a number of occasions letters were sent to members of particular committees or to all members of the Senate or the House urging them to consider the A. M. A.'s reasons for favoring or opposing certain bills. In most cases these letters were sent by Dr. F. J. L. Blasingame, A. M. A.'s Executive Vice-President. More than 300 individual letters were sent by the Office to senators and representatives.

Office staff members also worked closely, officially and unofficially, with executives of a number of federal agencies, including the Departments of Defense, Commerce, Health, Education, and Welfare, and Treasury; Army, Navy, Air Force, and Coast Guard; Veterans Administration, Civil Service Commission, Federal Communications Commission, Small Business Administration, Federal Housing Agency, World Health Organization, Civil Aeronautics Board, Civil Aeronautics Administration, Pan American Sanitary Bureau, and Federal Civil Defense Administration.

The Forand Bill

The Office, as did the rest of A. M. A., gave top priority this year to efforts to defeat labor-sponsored legislation to provide, within the framework of Social Security, a compulsory health insurance program for the nation's 14 million aged persons. In addition, the office was active in connection with legislative developments on: the Jenkins-Keogh bill, the Hill-Burton bill, the new Aviation Agency, Medicare, Defense Reorganization, FHA loans for nursing homes, the White House Conference on the Aged, and many other important issues.

Relations with Other Medical and Related Groups

The Washington Office assists in the general efforts of the A. M. A. to establish and maintain cordial working relationships with other groups in the health and welfare fields for the promotion of joint legislative efforts and for improvement of various programs, governmental and private.

To this end Office personnel have been in steady contact with the American Hospital Association, American Association of Retail Druggists, American Dental Association, American Association of Nursing Homes, the U. S. Chamber of Commerce, American Thrift Assembly, several national insurance organizations and many others.

There was particularly close coordination between the Office and the American Thrift Assembly, formed by the A. M. A. and a number of other groups to promote passage of the Keogh retirement bill. The Washington Office Director (and subsequently, the Acting Director) was a member of the ATA executive committee and assisted in shaping ATA policies and administrative practices; a representative of the Office met regularly with ATA officials, and legislative efforts of the two were closely correlated and coordinated.

On invitation, Office personnel visit state medical society meetings and take part in their programs. An increasing amount of time is devoted to answering the requests of state and local societies and acting as their Washington "agents" in dealing with Congress and government agencies. The staff also keeps in close touch with A. M. A. councils that have Washington responsibilities, and Washington personnel frequently attend council and bureau meetings in Chicago and elsewhere. Where possible, the Office assists them in relations with Congress and Federal officials.

Publications

Beginning in September, 1958, the Washington Office will cover Washington for the new bi-weekly AMA News. During 1958 the Office continued its editorial projects, which were:

The AMA Washington Letter, generally held to four pages, a weekly roundup of important medical news in Washington; during the Congressional session the Letter carries a Legislative Boxscore when developments warrant.

The Quarterly Legislative Review, a publication of varied length that summarizes each three-months' Congressional activity.

Legislative Analysis, generally weekly, but published only while Congress is in session, a detailed report on all medical bills introduced. This service is mailed to a limited list, including House of Delegates, Board of Trustees, Committees, state secretaries and other state society officials, auxiliaries and others who are required to follow Washington legislation closely.

Washington News in The Journal, two pages weekly.

The Month in Washington, an article of about 800 words condensing medical news for publication in state and regional journals.

Washington Feature, supplied on a non-schedule basis to The Journal, a more comprehensive treatment of a particular subject than is possible in the weekly news.

GP Washington News, supplied monthly to GP, the journal of the Academy of General Practice.

Federal Medical Legislation, in The Journal, a summary of bills introduced.

New Physician Column, monthly coverage for the journal of the Student American Medical Association.

Special Reports, published when developments warrant, this year on such subjects as the Forand bill, the Jenkins-Keogh bill, the President's budget message. The most widely republished Special Report is an annual summary and short analysis of every health or medical program that can be located in the new appropriations. During the session these Special Reports are a particularly valuable legislative tool, enabling the Office to alert rapidly an active segment of the profession when a situation becomes critical.

A single mailing list is used for the Letter, Special Reports, and Quarterly Legislative Review. "Sudden death" cards are used every two years to hold down the circulation of the above publications to those who have a genuine and continuing interest in Washington developments. At the time the last such check was made (1957) there were 9,500 on the mailing list. Before the one month deadline set for return of the cards, more than 70% of the readers had replied, asking to have their names retained. Now the circulation—names added only on personal request—again has reached 9,500 in less than a year.

A growing and time-consuming responsibility of the Washington Office is to answer inquiries from the news services, newspaper bureaus, television and radio, magazine writers, other associations in the health field, government agencies, students, and other private individuals. Our library, now almost 3,000 volumes, is of help in this work.

DEPARTMENT OF PUBLIC RELATIONS

The period covered by this report is July 1, 1957, to June 30, 1958.

The Department of Public Relations continued and expanded its efforts to give both the public and the medical profession a positive, constructive view of the American Medical Association's policies, actions, and services. The program during this one-year period included numerous special projects, designed to achieve particular objectives, in addition to continuing activities aimed at channeling information to the press, television, radio, general public, state and county medical societies, individual physicians, and other organizations.

Advisory Committee

The Advisory Committee to the Director of Public Relations, which met four times during the year, gave valuable advice concerning medicine's public relations problems, current programs and future projects. Members of the Advisory Committee were:

Mr. Robert D. Potter
Executive Secretary, Medical Society of the County of New York
Mr. John E. Farrell (Sc.D.)
Executive Secretary, Rhode Island Medical Society
Mr. Ralph R. Marshall
Executive Secretary, New Mexico Medical Society
Mr. W. Harold Parham
Assistant Managing Director, Florida Medical Association
Mr. Donald L. Taylor
Executive Secretary, Iowa State Medical Society

Mr. George Saville
Director of Public Relations, Ohio State Medical Association
Mr. Ed Clancy
Director of Public Relations, California Medical Association
Mr. John C. Foster
Executive Secretary, South Dakota State Medical Association
Mr. Robert I. Howard
Executive Secretary, Medical Society of Virginia

Press Relations

Annual Meeting.—Total press room registration at the San Francisco meeting, June 23-27, was 129, including 51 newspaper and news magazine reporters, 8 magazine and free lance writers, 38 reporters from medical, technical, and trade publications, and 32 medical public relations personnel. Press coverage was heavy, and especially wide use was made of stories on Dr. Louis Orr's quackery speech, the use of hypnosis for heart surgery, the A. M. A. policy action on hypnosis, the controversy over the 1960 annual meeting city, and the policy action on the UMWA Welfare and Retirement Fund. For the first time, scheduled press conferences were held on scientific subjects, including space medicine and hypnosis for heart surgery. These 10 conferences were well attended and produced excellent stories.

Clinical Meeting.—The Philadelphia session, Dec. 3-6, was covered by 18 newspaper, news magazine, and wire service reporters and 16 from medical and trade publications. Publicity results were good, especially on the GP of the Year award to Dr. Cecil W. Clark, physician hero of the Louisiana hurricane, and the A. M. A. policy action on water fluoridation, which also received extensive editorial comment.

Special Conferences.—The department provided news coverage for the various annual conferences and special meetings sponsored by the Association, including the National Conference on Physicians and Schools, Mental Health Conference, Medical Civil Defense Conferences, Nutrition in Pregnancy Conference, Industrial Health Conference, Congress on Medical Education and Licensure, Rural Health Conference, and the Committee on Toxicology Conference on Labeling of Hazardous Substances. Press coverage varied according to the size and publicity potentialities of the meetings, but in most cases it included advance news releases, press room services, and special follow-up services.

Special Releases.—Subjects of special stories included Asian influenza, A. M. A. administrative changes, poliomyelitis "Operation Roundup," German claims for a cure of Gehrig disease, opposition to the Forand Bill, Dr. Julian Price's prognostication on the future of medicine, formation of the Joint Council to Improve the Health Care of the Aged, mental health, medical motion pictures, and the model law for the labeling of chemicals.

Continuing Projects.—The press section continued its production and distribution of the Secretary's Letter and the Weekly News Release. The news release was used more frequently to publicize the positive aspects of A. M. A. policies and projects, and greater use was made of material appearing in *Today's Health*. The staff prepared additional stories for use in newspaper medical supplements and answered an average of three or four queries per week from newspaper reporters and other writers. Work began on a health column which will appear this fall in the *Clubwoman*, publication of the General Federation of Women's Clubs.

Magazine Relations

Continuing its liaison with magazine editors and free lance writers, the department received an average of 10 requests per week for assistance in the preparation of medical or health articles. During this period general periodicals with a circulation of over one million published a total of 377 articles on such subjects. In addition, 49 articles appeared in the four major newspaper supplements, *This Week*, *American Weekly*, *Parade*, and *Family Weekly*. A weekly summary of these articles was prepared for publication in The Journal of the American Medical Association. Not one of these articles could be construed as detrimental to the medical profession.

Television and Radio Activities

Television continued to take an increasingly higher proportion of the total departmental effort. This resulted from a greater demand for A. M. A. help and a more aggressive information program to the industry by the department staff and the Physicians Advisory Committee on Television, Radio, and Motion Pictures. Although actual production was held to a minimum, preliminary work was begun for the filming of a 27-minute television program on the subject of food faddism. The department produced and distributed four feature newsclips, including a one-minute extract from Dr. Gundersen's inaugural address which was used on more than 200 TV news programs throughout the United States and viewed by an estimated 15 million people. The department continued its liaison with the National Association of Broadcasters, the three major networks, and free lance television workers; handled TV-radio coverage at special A. M. A. conferences and meetings, and counseled state and county medical societies on local programing.

TV Committee.—The Physicians Advisory Committee on Television, Radio, and Motion Pictures entered its third year of operation. The committee continued to fulfill its responsibility of assuring the accurate dissemination of medical facts and creating a favorable climate of public opinion for the medical profession through material presented via television, radio and motion pictures. In addition to continuing its liaison with the producers of "Dr. Hudson's Secret Journal," "Dr. Christian," and "Frontier Doctor," the committee reviewed and edited many scripts for network programs. This included several for such top-ranking shows as "Climax," "Playhouse 90," "Studio One," "Armstrong Circle Theatre," and "GE Theater." Work was continued with Paul Coates on his "Confidential File" syndicated series and with Art Linkletter's "House Party" program on CBS-TV. Current members of the committee are:

California:
  Eugene F. Hoffman, M.D., Chairman
  Robert W. Gentry, M.D.
  E. Vincent Askey, M.D.
  Dudley M. Cobb, M.D.
  Richard O. Myers, M.D.
  Marcus H. Rabwin, M.D.
  James F. Regan, M.D.
  Charles C. Stehly, M.D.
  Edward T. Tyler, M.D.
New York:
  Gerald D. Dorman, M.D., Co-Chairman
  Henry I. Fineberg, M.D.
  Renato J. Azzari, M.D.

Daily Bulletin of the Air.—As an experimental project, in cooperation with Merck Sharp and Dohme, a series of five television programs and five radio programs was presented over San Francisco stations to report daily news of the Annual Meeting to both physicians and the public. It was planned to edit kinescopes of the television programs into a motion picture for use on educational television and at medical society and hospital staff meetings.

TV Films.—The new film, "Whitehall 4-1500"—designed to show how the A. M. A. serves the American public—was introduced at the 1957 Public Relations Institute in late August. It was then used on 154 TV stations with an estimated audience of 10,088,126. Figures for three other PR films given wide distribution to the public via television were: "Even For One," 384 stations with 24,668,940 viewers; "Operation Herbert," 52 stations with 2,375,200 viewers, and "A Life to Save," 72 stations with 1,916,000 viewers.

Miscellaneous Activities.—Active assistance was given in production of "The American Doctor," presented on "Wide Wide World" over the full NBC-TV network in October, and "Salute to the Medical Profession," broadcast over the NBC Monitor radio network in June. The department provided news and research service to television newsmen and helped arrange appearances of A. M. A. representatives on both local and network shows, an example of the latter being the panel discussion on medical care costs on ABC's "Open Hearing" telecast.

Motion Pictures

Hollywood Films.—The Physicians Advisory Committee on Television, Radio, and Motion Pictures continued to cooperate with producers and directors of the major studios at various stages in the production of full-length motion pictures and short subjects with a medical story line.

PR Films.—Five 16-mm. films, each providing an important message from the medical profession, were distributed to school, church, and club groups with the following results: "Your Doctor," 267,718 people at 5,598 showings; "A Life to Save," 49,366 at 1,057 showings; "Even For One," 82,424 at 1,824 showings; "Operation Herbert," 68,700 at 2,200 showings; and "Whitehall 4-1500," 57,840 at 1,248 showings.

For Students.—The department cooperated with McGraw-Hill Text Films in the preparation of two motion pictures to be used for the instruction of high school and college students—one on the general subject of choosing a doctor and the other on quackery.

Coordination.—The department again coordinated promotion and publicity for medicolegal films and, in addition, helped with the promotion of "Helping Hands for Julie," which was produced by the A. M. A., American Hospital Association, and Squibb.

Literature Distribution

Distribution of pamphlets, leaflets, booklets, brochures, and reprints totalled 4,501,192 during the period of this report. Among the major new public relations pieces were "The Fifth Freedom," a leaflet on free choice of physician; "Do You Like to Make Decisions?" a leaflet emphasizing the importance of the individual physician's judgment, knowledge, and skill; "Health Care for the Aged"; "Which Way?" dealing with the issue of social security coverage for physicians; two brochures on the training of medical secretaries, and pamphlet reprints of "The Health of the Nation" by Dr. Julian Price and "Salute to the Medical Profession" by radio-TV commentator Alex Dreier.

Cooperative Projects.—In cooperation with A. M. A. councils, bureaus, committees, and other departments, staff members assisted in the production and/or distribution of "Protecting the Health of the High School Athlete," a booklet on sports injury clinics; the 1958 Rural Health Conference Digest; the new Principles of Medical Ethics; "Look Before You Leap," a placement bureau leaflet; the Personal Health Information Card (distribution 1,000,000) and the Family Health Record (distribution 1,579,300); and "Near Life, Near Death, Near God," a reprinted Journal article which was sent to more than 50,000 Catholic, Protestant, and Jewish clergymen in all parts of the country.

Special Projects

Medical Education Week.—The department again handled the Association's participation in Medical Education Week which was observed nationally from April 20-26 under the sponsorship of the A. M. A., Student American Medical Association, Woman's Auxiliary to the A. M. A., Association of American Medical Colleges, American Medical Education Foundation, and the National Fund for Medical Education. In addition to its work on the national coordinating committee, the department prepared and distributed four kits—on basic "working materials," community programs, radio and television, and newspaper promotions—at two-week intervals to over 2,000 state and county medical society officers, medical school deans, and public relations directors, S. A. M. A. chapter presidents, and Auxiliary state officers. Medical societies in 32 states, Hawaii, and the Isthmian Canal Zone reported local observances. National promotion also was obtained through science writers; medical, surgical and popular publications; JOURNAL advertisers; health columnists; and national advertisers.

National Science Fair.—For the third year the department also handled the Association's participation in the National Science Fair, held May 7-10 in Flint, Mich., under sponsorship of the Science Clubs of America. A special panel of A. M. A. judges selected four outstanding exhibits in the basic medical sciences, and the two top winners were well-publicized guests at the San Francisco meeting. The four citations at the 1958 Fair, largest ever held, were presented at a special A.M.A. luncheon attended by 820 students, teachers, regional fair sponsors, and medical and press representatives.

Farm-City Week.—The Association again cooperated with some 400 industries and farm, civic, and professional organizations in the third annual observance of Farm-City Week, held Nov. 22-28 with Kiwanis International as coordinating agency. The department's promotional work included communication with each state and county medical society, a suggested program of activities, liaison information, a general news release, and an editorial in THE JOURNAL. The Association also contributed toward the cost of producing advertising mats for distribution to U. S. newspapers.

Asian Influenza.—Cooperating with the Committee on Influenza of the Council on National Defense, the department carried out a program to help alert the public on the danger of an Asian influenza epidemic in the fall of 1957. In addition to the news releases already reported under press relations, informational packets were distributed to state and county medical societies, and promotional material—including a television spot and three radio spots—was made available to broadcast media. This project was carried out in conjunction with the Surgeon General's Office of the U. S. Public Health Service.

Poliomyelitis Inoculation.—Continuing the campaign initiated early in 1957 to stimulate public interest in poliomyelitis vaccination, the department distributed four issues of the "Physicians Against Polio" newsletter to state and county medical societies. Two reminder cards, for physicians to send to patients, were produced in cooperation with the National Foundation for Infantile Paralysis. Sample cards and order blanks were sent with a letter from A. M. A. President Allman to 200,000 physicians. This was followed up by a flyer to state and county societies and an ad in THE JOURNAL. Approximately 17,000 orders were received for 2,450,000 third shot reminders and 3,105,000 series reminders. The department also published a booklet on inoculation clinics, in cooperation with the N. F. I. P., and worked with the Advertising Council on two related poliomyelitis promotional campaigns.

Social Security for Physicians.—In cooperation with the Assistant Executive Vice-President and the Law Department, this department helped carry out a professional education program on the issue of compulsory OASDI coverage of self-employed physicians under the Social Security Act. This work included an editorial, a President's Page, and one of a series of three articles, all in THE JOURNAL; distribution of the "Which Way?" pamphlet to 200,000 physicians, and preparation of a comprehensive kit of informational materials used to fill requests from medical societies and individual physicians.

Forand Bill.—In cooperation with the Task Force set up to coordinate A. M. A. and medical society activities regarding the Forand Bill, this department helped develop the "Facts About the Forand Bill" leaflet and the "Health Care for the Aged" booklet. Separate mailings of these, accompanied by letters of transmittal, were made to 200,000 physicians, residents and interns. Prior to establishment of the special Task Force, this department prepared two speeches, two JOURNAL editorials, and one President's Page on the Forand Bill.

Science Writing Workshops.—To help improve understanding and cooperation between medicine and the reporters who cover scientific news for small and medium-size newspapers, the department conceived, arranged, and promoted the first two science writing workshops sponsored jointly by the A. M. A. and the National Association of Science Writers. Held in Syracuse, N. Y., and Cincinnati, with the active cooperation of state and county medical societies in those areas, each of the meetings drew about 50 reporters, medical society representatives, and persons from allied groups.

Proprietary Medicine Advertising.—At the request of the House of Delegates, the department laid the groundwork for a program to improve "truth and decency" in advertising over-the-counter medical products to the public. A meeting was held with representatives of the American Association of Advertising Agencies, American Association of Newspaper Representatives, American Newspaper Publishers Association, Association of National Advertisers, Columbia Broadcasting System, Magazine Advertising Bureau, Magazine Publishers Association, National Association of Broadcasters, National Better Business Bureau, National Broadcasting Company, and The Proprietary Association. Consensus was that voluntary arrangements should be made to screen questionable advertising of proprietary drugs, and the National Better Business Bureau was suggested as the best central agency for such screening. This department developed a five-point program which was approved by the Board of Trustees and the House of Delegates at the San Francisco meeting. As a result, the A. M. A. has become a subscribing member of the N. B. B. B., and plans are under way for another meeting with interested parties.

Services to State and County Societies

A. M. A. News Notes.—Twelve issues of this monthly newsletter on Association projects and services were distributed to state and county medical society editors, state executive officers and A. M. A. department heads and guides.

PR Doctor.—Six issues, including a special television issue, were distributed to provide state and county societies with practical news and examples of public relations projects. A new feature was initiated: a special one-page insert to be used with corresponding PR Exchange items as supplementary materials for PR in Action kits.

PR Institute.—The fifth annual Public Relations Institute, held Aug. 28-29, attracted approximately 400 representatives of state and county medical societies for discussions of public relations problems and exchanges of how-to-do-it information on such subjects as press relations, grievance committees, legislation, professional liability, and doctor-lawyer cooperation. PR aids were displayed, and at the closing session the participants received special packets containing summaries of all Institute presentations.

PR in Action Kits.—The special television issue of *PR Doctor* was added to the list of PR packets, bringing to 14 the total available on request to state and county societies.

House of Delegates Report.—The roundup story on House of Delegates policy actions was mailed on the final day of the Philadelphia and San Francisco A. M. A. meetings to all delegates, state and county editors and secretaries, A. M. A. officers and trustees, and other interested parties. The mailing list reached a total of 855 out of a run of 900 at the San Francisco meeting.

Counseling.—The department met a large number of requests from state and county societies for advice and/or materials in solving specific public relations problems or developing programs.

Services to Officers and Trustees

In providing assistance to the President, President-Elect, Executive Vice-President, and other Association officers, staff writers assisted in the preparation of 68 speeches, 12 President's Pages for THE JOURNAL, and two special by-line articles. The speeches—covering a wide variety of subjects involving A. M. A. policies, problems, and activities—were heard by an estimated 20,000 persons. Thousands of others read news accounts of the speeches or the full texts reprinted in journals.

Executive Assistant.—Work of the executive assistant assigned to the President and President-Elect also included 30 days of travel covering 14 trips to meetings in 13 states; arrangements for 12 press interviews or conferences; arrangements for 13 television and radio appearances; distribution of advance, press room, and follow-up copies of speeches; assistance on correspondence and itineraries; and editorial assistance on "Allman-Ack," a special booklet printed for the Philadelphia Brotherhood Week meeting in tribute to Dr. David B. Allman.

Presidential Inauguration.—For the sixth year the department handled all writing, arrangements, promotion, and publicity for the presidential inauguration ceremony, which at the 1958 Annual Meeting drew a capacity audience in the Rose and Concert Rooms of San Francisco's Sheraton-Palace Hotel. In addition to Dr. Gunnar Gundersen's installation and inaugural address, the program included choral music by the Oakland Shrine Chanters and presentation of the A. M. A. Distinguished Service Award and two Distinguished Layman's Awards. The department also arranged the President's Reception and Ball, which followed the inaugural ceremony.

General Services

In addition to activities reported in previous categories, this department also: published the *Daily Bulletin* at the A. M. A. meetings in Philadelphia (12,000 copies and 16 pages) and San Francisco (34,500 copies and 50 pages); produced 22,000 copies of the general program for the San Francisco meeting; handled photography and requests for prints at the Philadelphia and San Francisco meetings; carried out an expanded program of liaison with women's organizations, including medical assistants groups, Woman's Auxiliary to the A. M. A., General Federation of Women's Clubs, National Federation of Business and Professional Women's Clubs, and American Association of University Women; assisted the A. M. A. Membership Department and state societies in orientation and membership promotion programs; conducted the guided tour program at A. M. A. Headquarters, which accommodated 353 visitors; prepared the visual presentation for the Board of Trustees on the value of establishing the *AMA News;* sent out 300 packets on socialized medicine; and counseled other Association departments on a wide variety of public relations problems.

Conclusions

The work of the department is constantly expanding, and it also is felt that the public relations program is steadily improving as greater and greater emphasis is placed on positive, constructive activities.

COUNCIL ON MENTAL HEALTH

Since its last annual report the Council on Mental Health has held two Council meetings, November, 1957, and February, 1958. An Executive Committee meeting of the Council was held in April, 1958. The primary interests of the Council for the past year have been the formulation of a final report on the Medical Use of Hypnosis for consideration by the Board of Trustees, study concerned with the possible inadequacies of the Medicare Program, the formation of a Joint Committee between the Council on Mental Health and the Council on Industrial Health, and a strengthening of liason between the Council and the 46 committees on mental health of the state medical associations. This coordinating relationship is in great part carried on through the Annual Conference of Mental Health Representatives of State Medical Associations, which is held in November of each year.

Medical Use of Hypnosis

After a study of approximately two years the Council's *Ad Hoc* Committee on Medical Use of Hypnosis, forming a committee of members as a whole, presented to the Board of Trustees in May, 1958, its final report on the Medical Use of Hypnosis. The Board of Trustees recommended that the report be submitted to the House of Delegates for final action at the next annual meeting of the Association in June, 1958. At this meeting the House of Delegates, on recommendation of the Reference Committee on Hygiene, Public Health, and Industrial Health, approved the Council's report on hypnosis. This report, along with its bibliography, was published in the Sept. 13, 1958, issue of THE JOURNAL of the American Medical Association, page 186, and reprints will be made available to interested persons from Council headquarters in Chicago.

Committee on Alcoholism

The Council's Committee on Alcoholism has held two meetings, September, 1957, and January, 1958. Since the last annual report, the Committee's Manual on Alcoholism, consisting of a series of articles on the medical, physiological, psychiatric, and social aspects of alcoholism, along with guest editorials, in cooperation with the A. M. A. Bureau of Health Education, has been published, and is available to physicians at a nominal fee through the A. M. A. Order Department. In conjunction with the regular committee meetings, the Committee on Alcoholism has established "institutes" on alcoholism. The primary purpose of these "institutes" is to educate the physician, particularly the general practitioner, in the treatment of patients suffering with alcoholism. These "institutes" work on a cooperative basis with the state medical societies and are arranged only on the request of state medical societies in connection with their annual meetings. The first of the "institutes" was given in San Francisco in September, 1957, and the second in Galesburg, Ill., in January, 1958. A third "institute" is being planned with the Colorado State Medical Society for September of this year. The Committee has developed with the A. M. A. Bureau of Exhibits two excellent educational exhibits on alcoholism. The Classified Abstract Archive of the Alcohol Literature, a service for physicians at the Council's headquarters office in Chicago, is still maintained by the Committee.

Narcotic Addiction

Since the Council's Report on Narcotic Addiction was approved at the annual meeting in June, 1957, the Council's headquarters office has distributed approximately 1,500 copies of the report. Most of these reprints go to physicians, lawyers, and interested government agencies.

With the resignation of the former Chairman, Dr. Robert H. Felix, the Committee, under its new Chairman, Dr. Harris Isbell, has undertaken plans to collaborate with the A. M. A. Bureau of Exhibits in the establishment of an exhibit on Narcotic Addiction.

Joint Commission on Mental Illness and Health, Inc.

The Council has continued its active cooperation with the Joint Commission on Mental Illness and Health, Inc., during the past year. At the present time five members of the Council are also members of the Joint Commission, and Dr. Leo H. Bartemeier, Chairman of the Council, continues in his capacity as Chairman of the Board of Trustees of the Joint Commission. Dr. Richard J. Plunkett, Secretary of the Council, continues as Associate Director of the Commission's headquarters staff.

The Joint Commission now has 12 projects and field studies in the mental and emotional illness field actively under way. It has submitted two annual reports and plans to have its final report ready by the Fall of 1959.

The two most recent study projects undertaken by the Joint Commission are a study of the relationship between religion and mental illness, a project supported by the Rockefeller Brothers Fund, and a study of the epidemiology of mental and emotional illness including multiprofessional viewpoints on etiology and considerations related to the over-all ecology of mental illness and problems related to the communicability of mental and emotional illness.

In all of its aspects the work of the Joint Commission continues to be an extension of the interest of the Council and of the Association itself in providing for improvement in the care of mentally and emotionally ill patients.

Fourth Annual Conference of Mental Health Representatives of State Medical Associations

On Nov. 22 and 23 the Council sponsored its Fourth Annual Conference of Mental Health Representatives of State Medical Associations to consider related problems in the field of mental health. There were four discussion groups:

(1) The Role of the General Practitioner in Relation to the Specific Psychiatric Case.
(2) Blue Cross-Blue Shield and Other Voluntary Health Insurance Plans for the Psychiatric Patient.
(3) Relationship of the Psychiatrist in Private Practice to the General Hospital in his Community.
(4) Psychiatric and Related Mental Health Problems in Industry.

The Conference was chaired by Dr. Leo H. Bartemeier, Council Chairman. The guest speakers of the evening of Nov. 22 were Dr. Ernest B. Howard, Assistant Executive Vice-President of the Association and Dr. Frank E. Hartung, Associate Professor, Department of Sociology, Wayne University, Detroit. The Proceedings of the Conference have been published and distributed to all state medical associations and other participating groups. Copies of the Proceedings are available at headquarters office. The Council is now making preparation for its Fifth Annual Conference scheduled for Nov. 21 and 22, 1958, at the Drake Hotel, Chicago. Because of increased participation in the Conferences by state representatives and outside organizations, five topics will be discussed at the Fifth Annual Conference, i. e.:

(1) Emotional Block Versus Brain Damage in the Diagnostic Categories in Mental Retardation or Mental Deficiency in School Children.
(2) Communicability of Mental and Emotional Illness.
(3) Education for Psychiatric Medicine.
(4) The Joint Commission for Mental Illness and Health—Progress and Problems.
(5) Mental Illness and Health in the Aged.

These subjects will continue to be active interests of the Council during the coming year.

Woman's Auxiliary

In July 1957 the Council on Mental Health recommended to the chairmen of all state mental health committees that it would be helpful if the chairmen of the State Mental

Health Committees of the Woman's Auxiliary could sit as permanent guest members at each of the meetings of their state association committees on mental health. Since that time the Council has received a number of replies from these chairmen indicating that they were cooperating in this effort. The Council continues to give supervisory advice to the Woman's Auxiliary in the development of its programs on mental health.

Headquarters

Because of the increasing amount of work since its inception, the Council requested the Board of Trustees to appoint an additional member; and in December, 1957, Dr. Norman Q. Brill of Los Angeles was elected, thereby raising the total number of members to nine, and giving the Council better geographical representation. In the last year the Council has had representation on two committees of the Association, Dr. Walter Baer on the Committee on Rehabilitation and Dr. Hugh Carmichael on the Committee to Study Paramedical Areas in Relation to Medicine.

As in the past years, the Council continues a close liaison with other councils and committees at the Association headquarters. The Council also continues to work closely with many organizations in the field of mental health outside the American Medical Association. Some of these organizations are the American Psychiatric Association, the American Nurses Association, the National Institute for Mental Health, the American Association of Mental Deficiency, the American Bar Association, and the National League for Nursing, and continues actively to support the work of the Joint Commission on Mental Illness and Health.

COUNCIL ON RURAL HEALTH

During the past 13 years the Council on Rural Health has been motivated by certain basic concepts in our over-all philosophy of self-help and the following six guides to our thinking of health problems and their solution are:

1. That each of us is largely responsible for our own health; that through the many decisions we make daily we profoundly affect our physical and mental status.
2. That our inalienable right to life, liberty and the pursuit of happiness is ours *only* if we value it enough to preserve it for ourselves.
3. That everyone has an inherent right to knowledge. But that it is our responsibility to acquire the knowledge needed to accomplish our purpose, be that health maintenance or any other objective.
4. That it is the duty of each of us to be a good citizen and pull our full pound when it comes to promoting and defending the common welfare, our homes, our community, and our country.
5. That we do best when we join with other citizens of good intent and gain the advantages that accrue from organization and team work.
6. That as the world of medicine and the world of agriculture advance through constant change, we all do better for ourselves if we depend upon our own ability and upon our own determination to "Help Ourselves to Better Health."

A signal honor was bestowed on Mrs. Charles W. Sewell, a co-founder of the Council on Rural Health, during the A. M. A. annual session in San Francisco. Mrs. Sewell was cited for her humanitarian service in the field of rural health. The award is given to a distinguished layman who has served to advance the ideals of American medicine and also has contributed notably to the public welfare. She is the first woman to receive the medical organization's citation for distinguished service. Only five persons, including Mrs. Sewell, have received the award since it was established in 1948. The Council takes great pride in this well deserved recognition.

During the past three years the U. S. Department of Agriculture with the assistance of the Department of Health, Education and Welfare, has been conducting a number of pilot projects in some of the economically depressed areas in 31 different states. The purpose is revolutionary in that the activity of federal agencies is advisory, dealing with an organized group of local citizens representing a broad cross section of local opinion and leadership. Within the state the Agricultural Extension Service exerts some leadership through the County Extension personnel. The objective is to pursue all possible promising activities as decided upon by the local group affecting the resources, the health and the social and civil activities of the total population. This is a most promising effort in harmony with local free choice and with responsibility inherent with such freedom. Since health is one of the pursuits to be followed, the Council has pointed out to state and county medical societies this opportunity for leadership in all matters where sound medical practices are concerned. In May these 84 pilot county plans were reviewed at Memphis, Tennessee, at which the Council was represented by the Executive Director and the Chairman. The follow-up on this program comes within the scope of its field activities.

A new activity of the Council was the compilation, printing, and distribution of nine health discussion lessons for the National Grange to use as program material by leaders of state and Pomona Grange groups. Ten thousand of each, with various A. M. A. pamphlets were forwarded to the national office for distribution to state groups.

In October a two-day study conference was held at Purdue University for chairmen and members of state rural health committees which was attended by leaders in rural health from 23 states. This was a training program, a re-statement of the goals for the future and as assessment of achievements up to the present, with special emphasis on the philosophy and aims of the Council. Later a summary of the meeting, together with a 15 point program, was mailed to all chairmen, committee members and executive secretaries of state societies as an aid in carrying out their duties in the rural areas, and as an aid to newly assigned members of the various state committees. As a result of this activity, the House of Delegates, at the Clinical session in Philadelphia, December, 1957, took favorable action requesting the state medical associations to give further support and encouragement to their state rural health committees, and to form a closer liaison with and work with all farm organizations and rural groups.

The 13th National Conference on Rural Health was held in Jackson, Miss., March 6-8, 1958. The theme of the over-all meeting was "As the World Turns." The program was well balanced, ably presented, and enthusiastically received by the entire audience. The Council would like to pay particular tribute to the Mississippi State Medical Society for the gracious hospitality extended to the entire group during our National Conference last March. They were keenly interested at all times in every phase of our planning and cooperated in every way to make this meeting most successful. The entire membership as well as the staff extended every courtesy, for which the Council is most grateful.

During the year the Chairman has been privileged to attend rural health meetings in many areas of the country. They were well attended by many people of widely different interests, brought together by the common denominator of citizenship and a general interest in better health. The Council has been encouraged by the fine enthusiasm and enduring interest of lay leaders in this over-all problem. They seem especially encouraged and stimulated by the efforts being promoted by the medical profession through the A. M. A. In no other way could the participation of so many able lay leaders have been obtained. We have been impressed by the universal demand for the best in medical care. There is no market for known second-rate services. This is true on all levels of society. Our doctors have the same schooling and training wherever they locate and they all have the same opportunity to accept the challenges of the city or the greater challenge of the town. There are still many opportunities to locate and practice in places where one can be reasonably busy doctoring people who need him and want him. This is the essence of a satisfactory professional life to be found in greatest abundance among the sturdy, independent, self-respecting people who live in rural America. The Council has deeply appreciated the good advice and assistance accorded it by its five advisory groups. The American Farm Bureau Federation, The National Grange, The Association of Land Grant Colleges, Committee on Policy and Extension, and the Farm Foundation of Chicago have each contributed from their experience and wisdom to the shaping of a successful year. This year the Council has added to its advisory membership. The American Veterinary Medical Association has been invited to join us and give us the benefit of its experience in the rural health field.

The Executive Director spent only the first six months of this year in activities of the Council on Rural Health. The last half of the year he was engaged largely in over-all activities of the A. M. A. in the legislative field.

During the time he spent on rural health he visited 18 states in the further development of the longtime program of the Council. Six of these states were visited twice, first, to gather ideas from the leaders of organizations for the program of the National Conference on Rural Health and, second, as a follow-up in locating talent for the program.

The Executive Director, along with the chairman, spent a great deal of time in developing the program for the Second Conference of State Chairmen of Rural Health Committees which was held at Purdue University on Oct. 4-5, 1957.

It was during the first six months of the year that the farm magazine health column series was developed. This is the second year for this activity and, though it consumes a great deal of time in corresponding with individual physicians and with the editor who rewrites and adapts the original articles, this is considered one of the most rewarding activities of the whole program.

The Executive Director attended such important national meetings as the American Country Life Association, the National Association of County Agricultural Agents, the American Association of Land Grant Colleges and Universities, the American Farm Bureau Federation, the National Grange, and other similar organizations.

A number of addresses were made before state and regional groups and time was also spent in counseling, advising, and promoting rural health organizations.

During the second half of the year, while the Executive Director was traveling into the states in connection with legislation, contacts were made with rural health leaders and the program promoted as much as possible. A great deal of work has also been carried on by correspondence.

As in other years, the activities of the Council office have been concerned with routine duties which consist of acting as an information source and clearing house for various organizations in rural health areas. It continues to maintain close relationships with state medical societies and state committees concerning rural health matters; also carries out assignments delegated by the chairman and the members of the Council, which include contacts with farm groups and trips to various parts of the country in connection with selection of sites for our national conferences. The office also maintains a current roster of all state committee members and a mailing list of approximately 5,000. In carrying out plans for our 13th national conference a pre-conference flier and a conference program were designed, printed and distributed, as well as approximately 5,000 invitations. A digest covering our 13th national conference was compiled, printed, and approximately 2,000 copies have been distributed. Three executive sessions and two full Council meetings have been held, as well as the annual advisory meeting. The activities also include mimeographing and mailing of specialized material of interest to rural people, mimeographing and distribution of the monthly farm articles, etc.

The two pamphlets "Check and Know" and "Member of the Family—Your Doctor" continue in demand and approximately 5,000 copies of each have been distributed during the year; also, a large number of complete kits of material on rural health have been furnished on request.

The Council continues to send out in response to a vast number of requests the popular booklet "Medical Scholarship and Loan Programs." Our mailing also includes tearsheets, reprints, booklets, etc., supplied by the various departments of A. M. A.

The "Personal Health Information" cards, originally developed by the Council at the special request of the Farm Bureau Federation, have proved to be a most successful project. In cooperation with the Public Relations Department last year, one million of these Health Information cards have been given wide distribution throughout the country. In addition, 50,000 copies were distributed directly through the Council. This distribution does not include the printing of the wallet sized card which has been carried on by the American Farm Bureau Federation as its own special project for which it has assumed the expense of printing. The joint project carried on between the Public Relations department and the Council with the "Family Health Record" booklets has also been a most worthwhile endeavor, and approximately 91,000 copies have been distributed during the past year.

Six hundred fifty pamphlets on organic phosphate insecticide poisoning, with accompanying letter of explanation, were sent to all state rural health committees and directors of Extension services of the State Agricultural Colleges.

DIVISION OF COUNCILS OF THERAPY AND RESEARCH

The Division consists of the headquarters staff of the Council on Drugs, Council on Foods and Nutrition, Council on Medical Physics, Committee on Research, Committee on Toxicology, Committee on Pesticides, Committee on Cosmetics, Bureau of Investigation, and the A. M. A. Chemical Laboratory.

These departments have constantly endeavored to expand their activities and improve their programs of operation with the view of rendering a better service to the medical profession and also the general public. The development of new drugs and other new potential aids for the diagnosis, prevention, and treatment of disease has continued to proceed with constantly increasing rapidity. In order to meet this challenge the evaluation of data or evidence and the publication of concise and authoritative scientific reports has been increased significantly.

Members of the staff have answered numerous inquiries relating to drug therapy, nutrition, toxicology, clinical research, medical devices, and cosmetics. Not infrequently they have also been requested by other departments at headquarters to render an opinion regarding the scientific soundness of a proposed exhibit, article for publication, or medical motion picture.

The Director of the Division has continued to serve as Chairman of the Advertising Committee for the scientific publications of the A. M. A. In this capacity he has had the responsibility of making certain that all proposed advertising copy for these publications is screened in order to insure compliance with the A. M. A. principles governing advertising. The task of determining the eligibility of products for advertising has often been tedious and difficult, particularly when the findings of various clinical studies were in conflict. Products that were of unestablished therapeutic value have been ruled ineligible. Likewise, irrational or "shotgun" mixtures of drugs have been rejected for advertising. A very considerable amount of time has been spent in making deletions or appropriate revisions of proposed claims or statements which were judged to be in violation of our governing principles. Every effort has been made during the past year to continue the established policy of being as fair and consistent as possible in screening all proposed advertising copy and of maintaining our standards at as high a level as is both possible and practicable.

COUNCIL ON DRUGS

The activities of the Council for the period July 1, 1957, to June 30, 1958, were focused chiefly on its established function of providing unbiased information and timely reports on drugs and drug therapy as a scientific service to the medical profession. The Council's over-all program for fulfilling this obligation has comprised the following three broad areas of action: (1) evaluation of evidence and description of individual new drugs, including additional forms and uses of previously considered drugs; (2) reviews of drug therapy in specific diseases or clinical conditions; (3) consideration of special therapeutic problems involving individual or classes of drugs.

The administration and implementation of the Council's program entails the preparation and publication at headquarters of a biweekly confidential Bulletin which is sent to all members as a means of conducting all transactions and recording the proceedings of meetings. Additional special Bulletins are issued when necessary for action on urgent matters. In addition, the headquarters staff serves all other headquarters departments as a source of information on drugs, provides replies to numerous outside inquiries concerning therapy, and participates in the scientific activities and meetings of outside organizations which pertain to this field.

Evaluation of Individual Drugs

The evaluation of available evidence for individual new drugs, together with proposed new uses of previously described drugs, and the preparation of statements concerning them for publication in The Journal of the American Medical Association and in the Council's annual publication, New and Nonofficial Drugs (N. N. D.), continues to be the major and most important activity of the Council and its staff. It embraces the Council's fundamental program for evaluation of drugs which was instituted in 1955 to replace the former seal-acceptance procedure. During the period of this report the following operations basic to this activity were accomplished: (*a*) consideration and adoption of nonproprietary names for 35 new compounds (prior to their evaluation and/or introduction for clinical use) through negotiations with American commercial sources and in cooperation with the U. S. Pharmacopeia, National Formulary, National Institutes of Health (in the case of biologics and addicting drugs), World Health Organization and British Pharmocopeia Commission; (*b*) evaluation of scientific data and reports of investigations (usually furnished through the cooperation of manufacturers) by direct contact with more than 150 expert outside consultants, and the members of the Council; (*c*) preparation by the staff, together with review and authorization for publication by the Council as a whole, of new monographs for 45 previously unevaluated drugs, including additional salts and esters; (*d*) preparation and similar consideration for publication of 5 supplemental statements on additional uses or routes of administration of previously evaluated drugs; (*e*) transmission of statements for publication to all cooperating manufacturers, including consideration of their valid criticisms, prior to release of statements for inclusion in The Journal and in N. N. D.; (*f*) revision of New and Nonofficial Drugs, 1958, together with appropriate chapter and sectional changes which resulted from the incorporation of 48 new monographs and the omission of 13 monographs on drugs no longer marketed or sufficiently well-known to make their further description unnecessary.

In conjunction with the publication of monographs, the Council instituted in The Journal and in N. N. D. 1958, the listing, in appropriate generic terms, of available pharmaceutical dosage forms and sizes or strengths of individual drugs, as an aid to prescribing. This additional feature of Council monographs was announced and simultaneously implemented as a change in operation in The Journal of Sept. 13, 1958. The Council also adopted and implemented a uniform system for expressing metric dosage and dosage sizes so as to state all amounts of 1 gram (Gm.) or more in terms of that unit, and all lesser amounts in terms of the milligram (mg.), except where the microgram (mcg.) has been established for highly active drugs such as cyanocobalamin (vitamin B_{12}).

At the close of the current period, a total of 29 new drugs were under various stages of evaluation with a view to publication of monographs on their actions, uses and dosage.

Reviews of Drug Therapy

Sponsorship of a continuing series of reports on the status of therapy in specific diseases or clinical conditions, prepared by selected outside authorities, constituted the second most intensive activity of the Council. Its continuation was considered essential to supplement the Council's statements on individual drugs. The preparation of reports on 25 additional topics was authorized for future publication over a two year period. A total of 9 reports of this kind were published during the year and included such important medical subjects as rheumatoid arthritis, infectious hepatitis, upper respiratory infections, and anemias. The Council also published a special report of the 1957 Veterans Administration–Armed Forces Conference on Chemotherapy of Tuberculosis, reviewing recent developments in the treatment of that disease.

Special Therapeutic Problems

Several special problems involving drugs and/or therapy were considered during the period covered by this report. The Council published 4 reports on the following varied subjects: dosage of vitamin K in hemorrhagic disease of the newborn; potential hazards of meprobamate; psychotherapeutic drugs; methods for identification of hospital solutions and preparations of drugs. The latter subject was considered in connection with the employment of short-cuts such as color for distinguishing certain types of hospital solutions. Such methods were considered likely to increase rather than decrease confusion in identifying preparations of all kinds and accordingly were discouraged in favor of adequate and carefully read labeling. The Council jointly sponsored, with the Council on Foods and Nutrition, publication of a report on flavonoids in human nutrition and medicine. At the request of a special Committee on Influenza, the Council also adopted a report on antibiotics and influenza which was published with reference to the outbreak of an Asian strain of this infection.

The Council reconsidered jointly, with the Council on Foods and Nutrition, the highly controversial subject of fluoridation of public water supplies as a method of prophylaxis for dental caries, a matter referred to the Councils for further study and a report of findings for consideration at the December 1957 Clinical Meeting of the Association in Philadelphia. The Councils held a special joint meeting at A. M. A. headquarters in Chicago on Aug. 7, 1957, to hear the views of two prominent opponents and two proponents of fluoridation. On the basis of available information and evidence, the Councils subsequently transmitted a report confirming the safety and efficacy of the procedure which was adopted by the A. M. A. House of Delegates (Proceedings of the Philadelphia Meeting, *J. A. M. A.* 166:1616 [March 29] 1958).

At the request of a special Committee on Amphetamines in Sports, the Council sought to obtain from several authorities information concerning the effect of such stimulants on the physical performance of trained and untrained athletes. The Council transmitted the data obtained for consideration by the committee.

Membership

Through nominations submitted for consideration by the Board of Trustees, Dr. Arthur C. Curtis, Dr. James P. Leake, and Dr. Torald Sollmann were re-elected to membership on the Council for additional five-year terms extending through 1962. By similar action, Dr. Louis S. Goodman was elected to fill the unexpired term, extending through 1959, created by the resignation of Dr. Joseph Stokes Jr.

Annual Meeting

The annual meeting of the Council was held at A. M. A. headquarters in Chicago on Nov. 1 and 2, 1957. Dr. Torald Sollmann and Dr. James P. Leake were re-elected Chairman and Vice-Chairman respectively. The closing date for annual editions of N. N. D. was advanced from Oct. 1 to Aug. 1 to make the book available in January of each year. The Council voted to discontinue its sponsorship of two former book publications, Glandular Physiology and Therapy, and Fundamentals of Anesthesia, because of their limited sale and the availability of other adequate publications in these fields. The Council also dissolved its advisory committees on contraceptives, dermatological vehicles, and radioactive isotopes to permit wider use of consultants as provided under its revised program of operation for evaluation of drugs. This was implemented with the understanding that members of these former committees could be invited to serve as individual consultants if the need for their opinions in these fields should arise. The Council authorized the selection of two full-time practitioners of general medicine to attend its next annual meeting as a means for gaining a closer perspective of the problems of the average physician.

The Council voted to circulate for comment by American drug and pharmaceutical manufacturers the principles promulgated by the World Health Organization for devising international names for drugs, with a view to their adoption and publication on an advisory basis, as a guide for achieving greater uniformity in the development of nomenclature for new compounds. On the basis of generally favorable replies received, including suggestions for improvement, the Council subsequently adopted and transmitted a proposed revision of the principles for consideration by the international organization.

Sponsorship of Symposiums on Drug Therapy

The Council also considered at its annual meeting and subsequently undertook sponsorship of an A. M. A. symposium and panel discussion on the Use and Abuse of Adrenal Steroids in cooperation with the George Washington University School of Medicine and the Medical Society of the District of Columbia. The program for the meeting, planned by a committee of the Council, was scheduled for presentation on Sept. 25, 1958. It was visualized that a meeting of this kind could provide physicians with additional practical clinical information on timely therapeutic subjects and attract wider attention to the work of the Council as an Association-supported scientific service to the medical profession.

COUNCIL ON FOODS AND NUTRITION

Nutrition education and information are the major interests of the Council on Foods and Nutrition. In the past year, increased emphasis has been placed on its program of supplying information designed to add to the armamentarium of the practicing physician. Sponsorship of symposiums, exhibits, articles in The Journal, publication of monographs, and review of institutional advertisements and other special educational materials have for many years constituted the Council's information program and, having proved this efficacy, the Council has worked to strengthen this program. Several new activities have been introduced this year including fellowships to medical students for research in clinical nutrition.

The Council carried out cooperative programs with a number of agencies during the year. One of the most interesting of these activities was in cooperation wi the Council on Drugs on the preparation of a report on the safety and effectiveness of the fluoridation of public water supplies.

The special interest in the possible relation of diet to atherosclerosis and cardiovascular disease that has been so prominent during the past 18 months has done much to focus attention on the general role of diet in the maintenance of health and on the place of nutrition in clinical medicine. The Council through its symposiums and special articles on this subject has been one of the leaders representing the medical profession in stimulating research while at the same time cautioning the public and industries to maintain a rational approach and reasonable attitude about dietary changes hopefully designed as safeguards against the onset of atherosclerosis.

Council Request Articles

The articles that are published in the Council column of The Journal are requested specially and reviewed by the Council. Council reports and statements are, of course, prepared by the Council itself. Judging by the reprint requests and citations in the scientific and the lay press, the articles are proving to be a most worthwhile activity.

Twenty-five request articles have been published in The Journal since June 30, 1957. In addition, 15 others have been received and are being processed for Council review before publication. Forty-two additional articles are being prepared at the request of the Publications Committee of the Council. Many of the articles are co-sponsored by the Nutrition Foundation as part of a cooperative program in nutrition education.

These articles represent a direct contribution to The Journal of approximately 110 pages. Nine articles in a series of 12 on "Modern Nutrition," are being published in *Today's Health* under the co-sponsorship of the Council and the Bureau of Health Education.

Three special monographs were published during the year, each made up of the articles from the Council-sponsored symposiums. Additional material that was not published when the collection of papers appeared in The Journal was included in two of the monographs. The titles are (1) "Some Inorganic Elements in Human Nutrition," (2) "Relation of Proteins and Amino Acids to Nutritional Health," and (3) "Fats in Human Nutrition—with Particular Attention to Fats, Cholesterol, and Atherosclerosis."

Council Statements

The 1957 report mentioned that the Council had completed and would soon publish a statement on multivitamin preparations as dietary supplements and as therapeutic agents. However, the statement was rewritten in the middle of 1957 and then submitted to the medical directors of various pharmaceutical companies for review. As a result of this review, the statement was again revised in October, 1957, and submitted for publication in January, 1958. On instruction from the Board of Trustees, and at the request of an *Ad Hoc* Committee of the American Drug Manufacturers Association, the statement was recalled from publication until a meeting could be arranged between the *Ad Hoc* Committee and the Council. At the meeting, which was held in New York City on April 11, 1958, the Council statement was thoroughly discussed in a way that appeared to be mutually satisfying to all concerned. The vitamin statement was extensively revised and finally adopted by the Council late in June, 1958.

Symposiums

The Council annually sponsors a symposium on some aspect of clinical nutrition. These symposiums, which have attracted large audiences, serve to highlight recent developments, to outline areas in need of further research, and to keep the physician informed of trends and changes in concepts. The publicity and news releases that emanate from the symposiums, plus the published reports in THE JOURNAL, further expand the area of influence.

The fall symposium, "Nutrition in Pregnancy," held on Oct. 11, 1957, at the University of Missouri, was sponsored by the Council with the cooperation of the Boone County Medical Society, School of Medicine, and the Adult Education and Extension Service of the University of Missouri. The speakers and their topics were as follows:

(1) Dr. Ray Hepner, Associate Professor of Pediatrics, University of Missouri Medical Center—"Influence of Maternal Nutritional Level on the Fetus and Infant"

(2) Dr. Icie Macy Hoobler, Consultant, Merrill-Palmer School Former Director, Research Laboratory, Children's Fund of Michigan—"Metabolic and Biochemical Changes in Normal Pregnancy"

(3) Dr. Genevieve Stearns, Research Professor of Orthopedics, State University of Iowa—"Importance of Nutritional State of Mother Prior to Conception"

(4) Dr. Joseph Warkany, Professor of Pediatrics, University of Cincinnati—"Nutrition Experiments as an Instrument of Teratologic Research"

(5) Dr. William J. McGanity, Associate Professor of Obstetrics and Gynecology, Vanderbilt University School of Medicine—"The Effect of the Reproductive Cycle on Nutritional Status and Requirements"

(6) Miss Dorothy Vorhies, Associate Professor of Nutrition and Dietetics, Outpatient Department, University of Missouri Medical Center—"Dietary Habits During Pregnancy"

The Council, in cooperation with the Nutrition Foundation, Inc., held a week-long symposium as a scientific exhibit feature of the San Francisco A. M. A. meeting. This presentation, also called a question and answer symposium, was entitled, "Diet as a Preventive and Therapeutic Tool for the Doctor." Each day a particular aspect of clinical nutrition was discussed, e. g., diet in cardiovascular renal disease, including the sodium-restricted diet, diet in coronary artery disease, diet in hypercholesterolemia, and diet in disease. Although the session on cardiovascular renal disease was the most popular, the others, which included diet in certain problems of internal medicine, the nutritive value of foods, diet in health, and diet and weight control, were well attended. A total of 22 topics were presented and discussed informally. A rather complete summary of the symposium was published in THE JOURNAL (167:1514-1515 [July 19] 1958). Plans are being formulated for a similar question and answer symposium for the 1959 annual A. M. A. meeting.

Exhibits

The Council, in cooperation with the Bureau of Exhibits, constructed a new exhibit entitled, "You Can Reduce," which has proved to be very popular. The exhibit demonstrates how to formulate a basic reducing plan tailored to fit the needs of the individual. The viewers can participate physically in three different ways, thus assuring their interest.

The staff of the Council office showed exhibits at seven professional meetings during the year.

Review of Educational Materials

The Council statement of review, granted for use on educational advertising and other informative materials, has become an important symbol of quality. The Council reviews these materials prepared to inform the public and the profession of the nutritional and physiological values of foods without reference to specific brands, processors, or distributors. The distribution by the food trade associations of some of these booklets and charts has exceeded 10 million.

During the year under consideration, the Council reviewed for medical soundness 55 educational advertisements, three booklets, and several charts. These materials were submitted principally by the American Meat Institute, the National Dairy Council, the American Institute of Baking, and the National Live Stock and Meat Board. A large number of advertisements, booklets, manuscripts, scripts, and films were reviewed by the Council office. These materials, of course, carry no statements of the fact that the A. M. A. review was made.

Joint Report of the Fluoridation of Public Water Supplies

The Board of Trustees directed the Council on Drugs and the Council on Foods and Nutrition to prepare a joint report on the safety and effectiveness of the fluoridation of public water supplies. Previously, the Councils had prepared a joint statement on the safety of fluoridation, which was published in 1951. At that time the opinion was expressed that "The use of drinking water containing up to one part per million of fluoride is safe." The 1957 report was prepared by the two Councils and presented to the Board at the Clinical Session in December, 1957. The Board transmitted the report to the House, which accepted the report as submitted.

Cooperation with the Nutrition Foundation

The Nutrition Foundation, New York City, is an incorporated organization formed by the food industry for the support of basic research and education in the science of nutrition. As part of a medical and nutrition education program, the Foundation cooperates with the Council on Foods and Nutrition in several activities.

The Nutrition Foundation sponsors the Joseph Goldberger award in Clinical Nutrition that is presented by the Board of Trustees of the A. M. A. in cooperation with the Council. The Goldberger award for 1958 (a plaque and $1,000) was presented in absentia to Dr. Virgil P. Sydenstricker, professor emeritus of medicine at the Medical College of Georgia. Dr. Sydenstricker has made outstanding contributions to the knowledge of nutrition and has done extensive research on nutritional deficiency diseases.

The Nutrition Foundation cooperated and helped support the Council program of request articles for the Council columns of THE JOURNAL. These articles were discussed earlier in this report.

A further activity initiated during the year in cooperatoin with the Foundation provides for 10 annual fellowships to qualified medical students for intensive research under faculty supervision. The purpose is to stimulate medical students to take an active interest in clinical nutrition. These fellowships of $600 each are granted in honor of the Joseph Goldberger award recipients. The first awards, given in 1957, were presented in honor of Dr. Paul György. Ten students selected from 40 applicants were granted the fellowships for use during the summer period.

Committee on Gastrointestinal Dietary Therapy

The Council, in cooperation with the American Dietetic Association, is sponsoring a committee to study the diets commonly used in the therapy of gastrointestinal diseases.

The committee, under the Chairmanship of Dr. Franz J Inglefinger, Massachusetts Memorial Hospital, is exploring current practices and concepts as a prerequisite to making recommendations for the necessary research. The work of this committee should lead to a more rational concept of the so-called soft, bland, or low residue diet.

Restricted Sodium Diet Booklets

Three diet booklets, describing severe, moderate, and mild sodium restriction at several caloric levels, have been produced in cooperation with the American Heart Association, the American Dietetic Association, the U. S. Public Health Service, and the Nutrition Foundation, Inc. These booklets, distributed by the local chapters of the American Heart Association, have proved to be most useful to the physician and to the diet therapist. In addition, table top exhibits and supporting materials have been prepared in order to promote the use of these booklets.

Activities of the Office of the Secretary

The Secretary and Assistant Secretary participated in a number of programs as representatives of the Association. These included formal addresses before many food trade associations and state and national professional organizations. Many of the addresses were reproduced in the appropriate trade association journals. A number of the articles were written by the Secretary.

The Council office was pleased to cooperate with the editorial department of The Journal in a consulting capacity for the section entitled, "Questions and Answers," and for a number of articles and editorials. The office was called upon many times to review articles for *Today's Health* and for the Public Relations Department. Reciprocal cooperation was enjoyed with these departments and with the other departments and bureaus of the Association.

Organization

Dr. Charles S. Davidson is the Chairman of the Council and Dr. John B. Youmans the Vice-Chairman. Dr. Wendell H. Griffith was re-appointed to another five-year term with the Council.

The Council held its regular fall meeting at Columbia, Mo., on Oct. 11, 1957. Two special meetings were also scheduled during the year. One was held on Aug. 7 with the Council on Drugs to hear testimony on the fluoridation of public water supplies, and the other was held in New York on April 11, 1958, with the *Ad Hoc* Committee of the American Drug Manufacturers Association to discuss the Council statement on multivitamin preparations. The regular spring meeting of the Council was held in San Francisco in June, 1958.

Several Council members received recognition for their outstanding contributions in the fields of science and administration.

Dr. Conrad A. Elvehjem, a member of the Council of long standing, has been appointed President of the University of Wisconsin. He had been Chairman of the Department of Biochemistry since 1944 and Dean of the University Graduate School since 1946.

Dr. George R. Cowgill was presented the Osborne and Mendel award of the American Institute of Nutrition. The award was given in recognition of his many pioneer and subsequent fundamental research contributions to our knowledge of the B vitamins and of protein nutrition; and for his numerous other broad contributions to the science of nutrition as a teacher, as editor of *The Journal of Nutrition*, and as an expert advisor in the field.

Dr. John B. Youmans is retiring as Dean of Vanderbilt University Medical School at Nashville and will begin an assignment as technical director of research in the office of the surgeon general.

Dr. Grace A. Goldsmith has been selected as the new chairman of the Food and Nutrition Board, National Research Council. She has been vice-chairman for several years and has taken over the chairmanship upon Dr. Elvehjem's resignation.

Dr. David B. Hand returned as head of the Department of Food Science and Technology at the New York State Agricultural Experiment Station after a leave of absence on special assignment with UNICEF.

COUNCIL ON MEDICAL PHYSICS

This report covers the period from July 1, 1957, through June 30, 1958, and is the second Annual Report of the Council, which was organized in mid-1956. The Council studies and reports to the profession and to the public on general classes of medical apparatus and on problems and techniques which involve the application of physical and biophysical principles in medicine.

During the past two years, the mouth-to-mouth method of artificial respiration has received much attention in the public press. Believing that physicians would be interested in knowing of the scientific data in support of the efficacy of this method, the Council invited a number of workers who had done substantial amounts of research on this technique to contribute to a symposium on the subject. A symposium consisting of four papers was published in the Council columns of The Journal in May, 1958. While, if properly applied, this method of artificial respiration can be effective in infants, small children, and adults, it has, up to the present time, been recommended for general use primarily in infants and small children. A study of the scientific data and of the other factors involved is being conducted by the Council and the publication of a general evaluation statement is planned.

The inhalation of negative air-borne ions has been proposed for the relief of asthma, hay fever, the improvement of the feeling of well-being, and for a number of other conditions. This controversial subject is under evaluation by the Council at the present time. The evidence in support of the pros and cons of electrical stimulation of the muscles of respiration as a means of artificial respiration is being reviewed and the report is to be published shortly. The use of radioactive (beta) sources in the treatment of eye diseases is now being reviewed by Council consultants and will soon appear in the Council columns of The Journal.

At the December, 1957, Clinical Session and at the June, 1958, Annual Meeting, the Council sponsored an exhibit on emergency artificial respiration. The exhibit included (1) mechanically animated figures demonstrating the back-pressure arm-lift method of artificial respiration; (2) a description of various manual methods and the mouth-to-mouth method of artificial respiration; and (3) charts presenting data on the efficacy of these various methods of artificial respiration.

For a number of years the Council on Drugs has sponsored the publication of the book "AMA Fundamentals of Anesthesia." Because a number of other very similar books are now available to the profession, that Council decided not to continue with the publication. The Council on Medical Physics then decided to explore revision of the book so as to place more emphasis on the various types of apparatus found in the operating room, including anesthesia equipment, other respiratory equipment, cardiac monitors, defibrillators, and pacemakers. It is also planned to devote attention to the problems of operating room safety and explosion hazards.

During the year the Board of Trustees asked the Council to consider the advisability of establishing a Committee on Atomic Medicine and Ionizing Radiation and after study the Council recommended that such a Committee be established. The Board approved the recommendation and the House of Delegates concurred at the June, 1958, Annual

Session. Careful attention is being given to the selection of the members of the Committee in order to expedite its activities.

During the period of this report 1,032 reprints were distributed from the Council office. These covered such diverse fields as the therapeutic uses of ultrasonic energy, artificial respiration, ozone apparatus, uses of diathermy, therapeutic exercise, instruction sheets for building physical therapeutic devices such as the shoulder wheel, hand exercise table, walker, electrical muscle stimulators, and the whirlpool bath. Also distributed were 59,550 pocket-size instruction cards on the back-pressure arm-lift method of artificial respiration. A new pocket-size instruction card was developed which also included the mouth-to-mouth method of artificial respiration for use in infants and small children. This card became available in June, and approximately 300 were distributed to the end of that month.

The program of the new Council has come along slowly, yet on a sound procedural basis. The coming year promises to be an even more productive one in terms of service to the profession and to the public.

COMMITTEE ON RESEARCH

During the current year the activities of the Committee on Research have been expanded and steps have been taken to revamp procedures.

Cooperative Investigation

The Committee on Research is awaiting the final report of the Subcommittee on Breast and Genital Cancer in order to determine the effectivenes of collaborative reporting developed in conjunction with this study. This approach may be of value in the study of unresolved problems in which no investigator has a large enough series of cases to warrant publication of conclusive findings.

Subcommittee on Breast and Genital Cancer.—The Subcommittee on Breast and Genital Cancer, reconstituted from the Cancer Study Group of the former Subcommittee on Steroids and Hormones, has completed the reanalysis of the case reports received in the study and, at the present time, is engaged in the preparation of the final report. It is anticipated that the report should be ready for publication at an early date. The Subcommittee intends to distribute an auxiliary report to interested parties containing all of the statisical information derived from the study. In this way the complete information on all phases of the study will be made available to everyone. It is hoped that this auxiliary report will be distributed soon after the final report is made to the Committee on Research. The Subcommittee felt that sufficient progress had been made in the reanalysis to permit the presentation of a preliminary report at the Seventh International Congress on Cancer, in London, England, on July 7, 1958.

Subcommittee on Diabetes and Pregnancy Wastage.—The Subcommittee on Diabetes and Pregnancy Wastage was expanded during the year so that there is representation from eight geographic regions of the country. The scope of the study has been expanded, and under the present plan, a series of patients treated with steroids and hormones will be compared with a series treated with long-acting preparations and a series of untreated controls. It is anticipated that this study will require at least two years for the accumulation of sufficient data which would form the basis of a report. The Subcommittee intends to correlate the microscopic findings from a study of the placental tissue and autopsy specimens with the clinical use of the drugs.

Subcommittee on Blood Dyscrasias.—The Subcommittee on Blood Dyscrasias was expanded during the year and its membership has geographic representation from eight areas of the country. The Registry on Blood Dyscrasias, conducted by the Subcommittee, has completed a two-year pilot study and since 1956 has received 356 case reports submitted by 143 physicians. The Subcommittee on Blood Dyscrasias has reviewed the work of the Registry and as a result has concluded that the Registry has served to alert physicians to the possible toxicity to the hemopoietic system of some of the newer therapeutic agents. The Subcommittee proposed that better coverage could be obtained if the number of collaborators were increased and steps were taken to provide wider distribution of the information. It is hoped that through such an expanded program the resources of the Registry may be made more valuable to the medical profession.

Educational and Informational Projects

The Committee on Research authorized the formation of a Subcommittee on Publications to solicit original articles, abstracts, and reviews concerned with research advances in the basic medical sciences. However, to date, little progress has been made because of an apparent duplication between units of the A.M.A. which has now been resolved; it is hoped that the Subcommittee will soon transmit material for publication. During the year the Committee on Research authorized the publication in The Journal of a statement by the Subcommittee on Blood Dyscrasias entitled "Blood Dyscrasias Associated with Promazine Hydrochloride Therapy"; an article entitled, "Drug Reactions, Enzymes, and Biochemical Genetics" by Arno G. Motulsky, M.D.; and a statement entitled "Classification of Types of Hypertension," by Drs. Albert A. Brust, George A. Perera, and Robert W. Wilkins. During the year the headquarters staff arranged a Conference on Staphylococcic Infections in Hospitals and representatives of national professional and public health organizations met in Cleveland, on Nov. 14, 1957, to consider this problem. The participants of the Conference drafted a report which the Board of Trustees accepted and sent to the Joint Commission on Accreditation of Hospitals for consideration and action. This conference has served as a stimulus for a number of meetings by several of the organizations which sent representatives to Cleveland. In addition, a number of hospitals have created "Committees on Infection" to investigate and develop control measures within their own institutions as recommended by the Conference. Interest has been manifested in the Proceedings of the "Conference on Comparison of the Biological Properties of Steroids and Hormones" and a number of requests have been received from overseas for copies of this transcription.

Grants-in-Aid

The Board of Trustees increased the appropriation for this program to meet the estimated increase in the number of requests for funds anticipated for 1958. The Subcommittee made 88 awards, totaling approximately $30,000, from among 112 applications received—of these awards, 82 went to medical schools and 6 went to other medical institutions. The Subcommittee's records show that 38 research projects, which received grants prior to this year, were the basis of articles appearing in scientific periodicals.

COMMITTEE ON PESTICIDES

This is the ninth annual report of the Committee on Pesticides. During the past year, the following activities were engaged in by the Committee in furtherance of its study program on the health hazards of pesticides.

Educational Activities

The series of Committee reports reviewing medical and public health aspects of pesticidal chemicals has been extended to 23 with the recent publication in The Journal of the report on the recurring problem of thallotoxicosis. A staff report discussing morbidity and mortality from the use of economic poisons in the United States is presently awaiting publication in the *A. M. A. Archives of Industrial Health.*

This report is based on an analysis of 37,000 incidents of poisoning reported by poison control centers, industrial commissions, and state departments of health for the period covering 1956-57. A preliminary report, by the Secretary, on antagonism of the lethal effects of parathion was also published in the *Federation Proceedings*, March, 1958. The full report of the study of chemical protection against parathion poisoning is awaiting publication in *Archives internationales de pharmacodynamie et de thérapie*.

Annual Meeting

The Committee held its annual meeting on May 10, 1958, at the headquarters of the American Medical Association. Current problems involving council status, legislation, and environmental health were discussed.

The possible hazards of fertilizers containing elements of chromium and nickel were next considered. A report of tumors found on autopsy of farm animals was considered and the question of whether this was due to the possible carcinogenic action of the contaminants in the fertilizer was reviewed. The high amounts of chromium and nickel found in fertilizer were considered to be due to poor analyses. No hazard to plants, humans, or wildlife could be ascertained from the available data.

The health hazards of pesticides to humans and wildlife from government sponsored mass pest control programs were next discussed. Opposition to broad-scale pest extermination programs conducted by the U. S. Department of Agriculture has recently culminated in a current court action in the East. An injunction has been sought to prevent the federal government from engaging in unwanted pesticide sprayings which arose from the application, last year, of 3,000,000 pounds of DDT in New York, New Jersey, and Pennsylvania. The plaintiffs are attempting to prove that the hazards to human and animal life from the use of pesticides on a large scale far outweigh their benefits.

The importance of this test case is related to whether government agencies will be prohibited from carrying out pest control programs because of allegations of health hazards. The plaintiffs attempted to show that the pest control program was dangerous, unusual, and illegal use of authority. This was difficult to establish since it was requested by three states and done in cooperation with the U. S. Department of Agriculture. The possible hazards from applying pesticides by aircraft over privately owned areas included injury to human health and contamination of food for animals and humans by pesticide residues. Attention was directed to the claim that no residue above tolerance was found to be present on any garden crops which were so sprayed.

The fire ant control program presents a similar problem in the South. It was pointed out that the people who complain about such programs are usually not the ones who have to face the insect problem. Local people who faced the fire ants requested the U. S. Department of Agriculture to aid them in controlling the pest. Steps were taken to minimize the hazards to beneficial forms of life by treating certain portions of the infested areas by air and others by hand. It was concluded that opposition to spraying programs is often caused by persons who do not know enough about such programs and are frightened by what they do not understand.

The problem of witch weed has also presented itself in this area. This parasitical plant attaches itself to the roots of the grass family and destroys crops such as corn. Cooperation, within government, of the various departments (Fish and Wildlife Service, United States Public Health Service, Department of Agriculture) concerned with the hazards of agricultural pest control programs has begun. The Committee believed that many obstacles could be avoided if conflicting interests within government could be consulted before new pest control measures were employed.

The Committee voted that both sides of the issue in these pest control programs should be pointed out when inquiries are directed to the Committee office. It recommended that steps be taken to provide clearer understanding of the hazards presented by the spraying programs by showing the steps that have been taken to prevent injuries from occurring, as well as the need for such programs which are of benefit to the public.

Compliance with the Miller Pesticide Amendment to the FDA Act was also discussed. This Amendment makes it illegal to ship food in interstate commerce if the residue tolerances are not complied with. It has been reported that pesticides are being used on forage crops too close to harvest and, as a result, the residues in the end products exceed the limits set by the amendment. No knowledge of any product put on the market with excessive amounts of residue was reported. However, it was pointed out that present methods of analysis may not pick up information on the toxicity of metabolites. The introduction of new agents is faster than research on the metabolite products. It was noted that the greatest proportion of DDT present in body fat of the general population came from residues of insecticide in meat; however, the amounts found are below the tolerance limits. A statement concerning the present status of this matter will be considered by the Commitee for future publication.

Service Activities

The Committee on Pesticides collaborated with other groups and organizations during the past year on problems of mutual concern. It continues to cooperate with the Interdepartmental Committee on Pest Control. The Committee participated in the selection of several generic names for new pesticides during the past year. Through the Secretary it maintained its representation on the Sectional Committee on Common Names for Pest Control Chemicals (American Standards Association) and Liaison Panel of Food Protection Committee (National Research Council). The Secretary participated in a symposium on pesticide poisoning at the annual meeting of the American Academy of Occupational Medicine at which time data was presented on Committee studies on the incidence of pesticide injury.

The Committee continues to provide information and assistance to the Committee on Toxicology in the development of a model law to require precautionary labeling of hazardous substances. It reviewed existing labeling statutes, as applied to pesticides, and the members participated in the two American Medical Association legislative conferences on the labeling of hazardous substances.

During the past year, the Committee was asked by physicians and private agencies to consider and render opinions on a variety of medico economic problems involving the hazardous potentialities of pesticides. It considered problems such as the hazards of dispensing of rodenticides (e.g., thallium and strychnine) in metal bottle caps, organic phosphate insecticide poisoning, clinical experience with malathion insecticides, and thallium poisoning. It also considered the merits of a product promoted for the removal of spray residues on fruits and vegetables.

The Committee was requested by a government agency to review the present status of vaporizing devices for insecticides. Cases of poisoning from the accidental ingestion of vaporizer pellets by children, agranulocytosis, other systemic injuries and possible chronic poisoning from continuous exposure to vaporizer fumes were compiled from Committee files. A request from industry to review and make recommendations on the occupational hazards of mercury fungicides is also under consideration. Dieldrin poisoning in public health workers, the hazards of arsenicals in medicated animal feeds and pesticide food contaminants as possible carcinogens are also being considered by the Committee.

COMMITTEE ON TOXICOLOGY

This is the fourth annual report of the Committee on Toxicology. The following is a résumé of its more important activities and accomplishments during the past year.

Educational Activities

The series of Committee reports has been extended to 10 with the publication of a report on "Recommendations of Committee on Toxicology on First-Aid Measures for Poisoning." An additional committee report on "Accidental Iron Poisoning in Children" is under consideration.

Two staff reports were published in THE JOURNAL on "Toxicity Problems of Cosmetics"(166:638 [Feb. 8] 1958) and "Principles for Precautionary Labeling of Hazardous Chemicals" (166:2154 [April 26] 1958). Other staff reports appeared in the *American Perfumer* ("Toxicity of Cosmetics"), *Journal of the American Pharmaceutical Association* ("Uniform Chemical Label Law"), *Canadian Medical Association Journal* ("Problems of Assessing Clinical Toxicity"), *Food, Drug and Cosmetic Law Quarterly* ("Labeling of Dangerous Household Chemicals"), and the *Home Safety Review* of National Safety Council ("Calculated Risks of Accidental Poisoning in the Home").

Legislative Activities

One of the most far-reaching projects the Committee has undertaken is the drafting of a model bill to require a warning statement in the identification of hazardous ingredients on the labels of chemical products. This bill is intended to reduce needless injuries and deaths by requiring hazardous chemicals to carry warning labels and to identify dangerous ingredients.

With the assistance of the Law Department, a survey of existing laws and regulations was compiled last year. This study revealed a hodge-podge of state and local regulations for the labeling of chemicals. The draft of a model bill has been finalized and meetings with interested parties in government, medicine, and industry are being held.

The first Legislative Conference was held on May 9, 1958, and it was attended by representatives of 40 national organizations such as the American Municipal Association, Michigan State Medical Society, American Pharmaceutical Association, Industrial Medical Association, National Safety Council, etc.

Attention was focused on the general nature of the problem as seen by the medical profession, public health officials, and the public, by remarks from a pediatric representative, and officials of the American Public Health Association and the National Safety Council. The principles which the Committee employed in formulating the provisions of a model law for labeling all types of hazardous substances were next reviewed. A comparison of the model bill with other tentative legislative proposals followed.

An industry-wide label law conference was held on July 25, 1958. The second meeting discussed proposed legislation requiring the declaration of hazardous ingredients and warning statements on the label and in the accompanying literature of household, commercial, and industrial packaged chemicals. Representatives of trade associations, toxicity testing laboratories, chemical trade unions, and other interested groups participated.

A film strip, for use on television newscasts, was recently prepared for the Committee on Toxicology by the Public Relations Department. The film strip is devoted to publicizing the Committee's efforts to obtain warning statements on the packages of chemical products and it highlights the Committee's recommendations on this subject. This film strip was released during the first week of May, 1958, and was sent to nearly 400 television stations throughout the country.

Service Activities

The Committee on Toxicology has collaborated with other groups and organizations during the past year. The Committee cooperated with the American Academy of Pediatrics and the American Public Health Association in a nationwide project to study the treatment of kerosene poisoning. Approximately 30 poison control centers and affiliated hospitals and clinics participated in this clinical study which is expected to take from three to five years. An initial result of this study has been the discovery of a means for determining blood levels of absorbed petroleum distillate. The value of anti-inflammatory agents such as steroid hormones has also been investigated.

Through the Secretary, representation is maintained on the Committee of the Chicago Poison Control Center, the Steering Committee of the National Clearinghouse for Poison Control Centers, the American Standards Association–Z66 Committee on Hazards to Children, and the U. S. Food and Drug Administration's Committee on Adverse Reactions to Drugs. During the past year, the Secretary addressed the American Academy of Occupational Medicine, the American Society for Pharmacology and Experimental Therapeutics, and the Food and Drug Law Section of the New York Bar Association.

During the past year, the Committee was asked by public and private agencies to consider and render opinions on a variety of problems involving the hazardous potentialities of chemicals. Among them were questions concerning the hazards of a dental cosmetic, packaging of hazardous nonmedicinal agents in capsule and tablet form, chemical additives to foods, revision of the New York City Sanitary Code, and the control of the sale of rocket chemicals. The sale of drugs in supermarkets, the limitations of "beer-can" fire extinguishers, drug data for poison centers, and hazards of carbon tetrachloride in hobby activities were also considered.

Several hundred inquiries on the health aspects and usefulness of pesticides were also answered by the Committee office. Assistance was provided various departments at headquarters in the preparation of book reviews, "Questions and Answers," reviewing manuscripts, and advertising on matters involving toxicology.

COMMITTEE ON COSMETICS

This is the ninth annual report of the Committee on Cosmetics. During the past year the Committee has continued to promote its educational program through the publication of reports, articles, and editorials in THE JOURNAL of the American Medical Association and in *Today's Health*; in presenting symposiums before professional groups; and in its inquiry and advisory service.

The Committee's major function continues to be its accumulation, preparation, and dissemination of information pertinent to its objectives. These are to promote a better understanding of the function, care, and significance of the skin, with special reference to the role of cosmetics and allied pereparations; to assist in the acquisition of new knowledge concerning the relationship between cosmetics and the skin; to emphasize the serious psychological implications of these conditions characterized by temporary or permanent skin disfigurement; to provide the public with such information as will enable it to wisely select and intelligently use cosmetics; to stimulate increased cooperation between the health professions and the toilet goods industry in providing the public with safe, effective, ethically advertised products; and to supply available data from our files to authorized persons.

At the invitation of the Medical Sciences Section of the American Association for the Advancement of Science, the Committee held its third symposium "The Human Integument–Normal and Abnormal" in December, 1957. This was a two-day program with half-day sessions devoted to the protective function of the skin, circulation and vascular reactions, sebaceous gland secretion and pathogenetic factors in premalignant conditions and malignancies of the skin. In the future, the symposium papers will be published as a monograph by the American Association for the Advancement of Science. Dr. Stephen Rothman, Chairman of the Committee on Cosmetics, is the editor. Discussions have been initiated on the 4th symposium of the Committee which will include papers on dermatologic and surgical procedures to improve the appearance of skin disfigurements.

During the past year, the following reports have been published in THE JOURNAL under the auspices of the Committee on Cosmetics: "Control of Axillary Sweating and of Body Odor" by Dr. Franz Herrmann and Dr. Marion B. Sulzberger; "Scientific Formulation of Cosmetics" by Dr. Paul G. I. Lauffer; and "Toxicity Problems of Cosmetics" by Dr. Bernard E. Conley. A report entitled "Suntanning-Potentiation with Oral Medication" prepared by Dr. Marion B. Sulzberger and Dr. Aaron B. Lerner has been authorized for publication. Other reports under consideration concern the use of antibiotics in cosmetics and the role of electrolysis in the management of hypertrichosis.

The office of the Committee on Cosmetics is now engaged in a study of resistance to inaccurate advertising claims of three health-oriented groups—nurses, physicians' wives, and *Today's Health* readers.

The Committee is particularly indebted to the many consultants who have so willingly offered and rendered assistance in special problems during the past year.

CHEMICAL LABORATORY

The portion of the Chemical Laboratory's program which demanded about three-quarters of its time and effort during the past year was concerned with its Tests and Assays program. This program involves the establishment of monographs of tests, procedures, and tolerances in cooperation with pharmaceutical firms for new and nonofficial drugs on the market. During this past year monographs have been completed and published on acetazolamide, acetazolamide sodium, aminopentamide sulfate, busulfan, carbazochrome salicylate, chlorquinaldol, cryptenamine, cryptenamine acetates, cryptenamine tannates, dimethicone, diprotrizoate sodium, diprotrizoic acid, ethchlorvynol, fludrocortisone acetate, hydroxyzine hydrochloride, hydroxystilbamidine isethionate, iodipamide, iodipamide methylglucamine, iodipamide sodium, isometheptene, isometheptene hydrochloride, isometheptene mucate, mecamylamine hydrochloride, methyprylon, monobenzone, sitosterols, tricyclamol chloride, tridihexethyl iodide, and zoxazolamine. Monographs on five other products were completed but not published for various reasons. Work is in progress and in most instances near completion for 28 other new drugs.

During this past year serious consideration has been given to the mechanism of operation of the Tests and Assays program and its aims. There has been much correspondence and consultation with organizations concerned with this problem and the matter will extend into the coming year.

Work has continued on the in vitro method for the determination of the rate of release of delayed and sustained release medication. The early phases of the work were embodied in a paper entitled "In Vitro Method for the Determination of the Rate of Release of Amphetamine Sulfate from Sustained Release Medication." This was published in the journal *Drug Standards.* There has been an exchange of ideas on these testing procedures with representatives of some of the pharmaceutical firms and with technical personnel of the Food and Drug Administration. Additional studies have been continued in an attempt to refine the testing method to embrace a wide range of pellet sizes, and to study the rates of release of several different preparations of sustained release capsules.

Because of a need for a rapid means for identifying tablets or capsules, there is being developed in our laboratory what we hope will be a simple, practical aid in the identification of drugs. The scheme relies on the physical characteristics such as size, shape, color, scoring, and similar features of tablets and capsules. A preliminary study of 500 products has been made using the proposed scheme and it appears to be a promising tool for the stated purpose. It would presumably be of value to physicians, attendants in emergency receiving rooms, toxicologists, police officers, and pharmacists—in particular, hospital pharmacists. The promise shown by the scheme and the favorable comments from several individuals indicate that the time and effort to carry out such a comprehensive scheme is warranted.

Arrangements were completed with the College of American Pathologists for the use of the Chemical Laboratory personnel and facilities to check hemoglobin standards available on the market. This is a phase of a certification program the College of American Pathologists is carrying out on hemoglobin standards.

An investigation was undertaken on certain solutions and solid phase materials with respect to their feasibility as ultraviolet reference standards.

Collaborative studies, at the request of an outside agency, for several of the cardiac drugs were conducted and completed.

The Laboratory this past year, as it has for many years, drew the structural formulas for the Council on Drugs book "New and Nonofficial Drugs." It took an active part in an advisory capacity to the Council on Drugs in its nomenclature program. An outgrowth of this has been the establishment of an extensive file which lists the generic name and structural formula of all new drugs which come to our attention. The Laboratory worked with and for many departments within the American Medical Association. The staff, almost daily, was requested by members of the Editorial Staff to check the accuracy of chemical statements and nomenclature in articles presented to the A. M. A. journals. Consultation by a member of the staff was regularly conducted with the A. M. A. Library personnel to advise on the classification of entries of chemical and pharmaceutical information for the Quarterly Cumulative Index Medicus. Members of the staff advised the Advertising Committee of the American Medical Association with respect to chemical and other technical statements appearing in advertising copy. Other services to American Medical Association departments were concerned with reviewing chemical articles proposed for publication in A. M. A. journals, answering queries from the Questions and Answers column in THE JOURNAL, supplying data on composition of products, and reviewing books for THE JOURNAL and the *New Physician.* Many letters of inquiry on technical matters were answered. Cooperative work and liaison have been maintained with the Food and Drug Administration, the United States Pharmacopeia, The American Dental Association, and the American Pharmaceutical Association.

Because of the work during past years on cigarette smoke and filters which was carried out and published by the laboratory, a member of the staff was requested to appear before the Blatnick Committee—a subcommittee of the United States House of Representatives. Testimony was given with respect to our studies. Later we were requested by the Federal Trade Commission to take part in discussions concerning the establishment of standard methods for testing cigarettes.

BUREAU OF INVESTIGATION

Of the several scientific activities of the Division of the Councils of Therapy and Research, the Bureau of Investigation differs only in the fact that it deals with the unscientific side of medicine. It is concerned with reporting

UMWA Welfare and Retirement Fund.—The report of the Committee concerned with relationships between the medical profession and the United Mine Workers of America Welfare and Retirement Fund is included in the report of the Council on Medical Service (page 1109).

Guides for Evaluation of Management and Union Health Centers.—In the previous Annual Report, the Committee noted that two changes would be recommended to the House in the text of these Guides, and these changes were approved by the House at the 1957 Clinical Session. Following the adoption of these changes, the Committee further recommended to the Councils on Medical Service and Industrial Health that the wording of two footnote references be changed in order to bring this Guide up to date. This recommendation was approved by the Councils at their meetings in June, 1958. Future printings of the "Guides for Evaluation of Management and Union Health Centers" will replace the reference "1954 Principles of Medical Ethics" with the statement "From the 1954 edition of the Principles of Medical Ethics which are contained in the Opinions and Reports of the Judicial Council (1957) and which have been incorporated in the June, 1957, Principles of Medical Ethics." The reference to "Guiding Principles of Occupational Medicine" will be deleted and substituted with "Statement on 'Scope, Objectives and Functions of Occupational Health Programs,' (J. A. M. A. 164:1104-1106 [July 6] 1957)."

1958 Survey of Union Health Centers.—In February, 1958, the Committee initiated its third Survey of Union Health Centers. The first two reports on these centers which were published in 1953 and 1954 contained descriptions of 12 and 17 health centers respectively. The new publication to be issued will contain descriptions of 27 of the approximately 50 such centers in existence. This survey is one of a continuing series to be conducted periodically in order to keep the medical profession informed of developments in this field.

In view of the numerous requests for copies of this publication, the 1958 Survey will include a copy of the revised "Guides for Evaluation of Management and Union Health Centers."

A Preliminary Guide for Measuring Work Absence due to Illness and Injury.—The last report of the Committee cited the studies, conferences, and various published materials on the subject of work absence which had created a considerable amount of interest among many physicians. It was also reported that the Committee was engaged in the preparation of a Guide on the basis of whose definitions and formulas a uniform group of statistics could be compiled by physicians in industry. The Preliminary Guide as approved by the Councils on Medical Service and Industrial Health will be published in pamphlet form and distributed soon to several thousand physicians and other personnel working in this field. The Committee is inviting comments on the Guides it has prepared, and plans to issue subsequent revisions based upon the suggestions and experiences of persons who use these Guides in their work.

Miscellaneous: Being prepared for publication and distribution to the medical profession is a "Summary Report on Health and Welfare Plans Under Collective Bargaining." This publication represents a distillation of some pertinent data relating to the provisions of hospital, surgical, and medical benefits in 300 plans which cover approximately five million workers, or over 40% of the total number of employees estimated to be covered by health insurance plans under collective bargaining as of the end of 1955. The material in the Committee's publication is based upon a study prepared by the Bureau of Labor Statistics of the United States Department of Labor. Its publication is considered to be an aid to those physicians and medical societies interested in various types of coverage under, and provisions of, collective bargaining agreements.

The Committee has been authorized by the two Councils to conduct a survey of small plant occupational health programs for the purpose of providing the profession with descriptions of various examples of how such programs operate, the types of service they provide, the relationships of physicians involved in such programs to physicians in the community, and other aspects of the operations of these programs which will be of interest to the medical profession. An important by-product of this study is expected to be the recognition by physicians of the value of such programs, particularly among establishments employing fewer than 100 employees.

The Committee has devoted some time to discussing the activities of different types of mobile units and the range of services they provide. Its future meetings will discuss this matter in greater detail, particularly to determine to what extent the screening of employees for the express purpose of detecting nonoccupational diseases is properly a part of an occupational health program.

Committee on Medical Education and Training (Standing Committee).—This Committee studied the matter of improving the teaching of occupational medicine. A statement, setting forth clearly what along the lines of occupational medicine should be taught to medical students, is now being prepared.

Joint Conference with Chairmen of State Medical Society Committees on Industrial Health.—The Council on Industrial Health has regularly held, on the eve of its Annual Congress on Industrial Health in January or February, a meeting with the chairmen of the committees on industrial health of the state medical associations. This meeting has proved valuable both to the state medical associations and to the American Medical Association. It has helped to keep the Council apprised of problems requiring its attention. At the same time it has brought to the Council, for the solution of such problems, the collective thinking of the state chairmen, representing the views of physicians engaged in occupational health at the "grass roots." Solutions thus developed have been of inestimable value to the states concerned, often sparing them from having to "learn the hard way." Additionally, the Council, attuned as it is at A. M. A. headquarters level to the views and policies of organized medicine at this level, has been able to communicate these views and policies to the state chairmen for dissemination to their "constituencies" for their information and guidance. Conversely, the state chairmen and the industrial physicians they represent, being in touch with privately practicing physicians at the "grass roots" level, have been able to gather the latters' views, which have a vital bearing on industrial medicine, and to communicate these views to the Council. This has made the pronouncements of the Council, and of the A. M. A. at the Council's instance, more realistic and helpful, as such pronouncements do not emanate from any "ivory tower" out of touch with the hard facts of life encountered in the day-to-day practice of medicine and industrial medicine.

Committee on Scientific Development (Standing Committee).—The Committee on Neurological Disorders in Industry (Dr. Edward D. Schwade, Milwaukee; Dr. Harry E. Tebrock, New York City), approved by the House of Delegates in December, 1957, held its first meeting in June and felt that a great deal of careful thinking was needed in order to determine in which direction the Committee should proceed. The Committee felt that workers with a neurological disorder were being greatly discriminated against by industry, and that the preparation of guides or standards for industrial physicians to follow would be extremely valuable. The Committee felt that it would have to do some research to see the problem from the standpoint of the industrial physician before it went ahead with its plans.

Committee on Industrial Medical Records.—This Committee, which has been inactive since presenting its original report on November, 1956, was reactivated under a new chairman. The Committee will study the 1956 report and proceed from there. It is expected also to develop record and report forms for use in the study and control of sick absence in industry. This material will ultimately be utilized in conjunction with the Guides which are being developed by the Committee on Medical Care for Industrial Workers

Committee on Occupational Cancer.—The Committee's report on "Occupational Cancer: Methods of Epidemiological Study" was published in THE JOURNAL in April.

Committee on Industrial Ophthalmology.—This Committee has prepared three statements, which have been submitted to THE JOURNAL for publication. They are: "The Effect of Fluorescent Light on Vision," "Use of Water in Emergency Treatment of Chemical Eye Injuries," and "Eye Safety Equipment." Two other documents are in draft form and are not yet ready for publication, namely, "Tonometry in Glaucoma Surveys" and "Guiding Principles and Procedures for Industrial Ophthalmic Nursing."

Committee on Occupational Dermatoses.—Dr. John G Downing, who had been chairman since 1952, resigned and was designated Emeritus Chairman of this Committee. Two reports of the Committee are ready for publication: "Occupational Dermatoses—An Introduction," and "Occupational Dermatoses—Predisposing and Direct Causes."

Committee on Medical Services for Construction Projects.—This new *ad hoc* committee was authorized by the Board of Trustees, on request of the Council, to be composed of Drs. Irving Tabershaw and Joseph Quigley, in order to give their previously written article, "A Guide for Medical Services for Construction Projects," the status of an official Council publication. The article has been seen by the members of the Committee on Scientific Development and is being prepared for the suggestions and approval of the Council for eventual publication in THE JOURNAL and reprinting later.

Joint Committee on Mental Health in Industry.—In line with an agreement reached by the Council on Mental Health and the Council on Industrial Health, after studies and discussions initiated some years ago by the Council secretaries, the two Councils requested the Board of Trustees for authority to establish this joint Committee. This authority was granted in February and, with the Board's approval, the Committee was formed. It plans to meet in November on the occasion of the meeting of the Council on Mental Health with the state mental health representatives. It is expected that this Committee will in good time bring to bear effective medical, joint psychiatric and occupational medical, leadership in the solution in industry of such mental health problems as alcoholism, interpersonal frictions, and proper placement and utilization for maximum productivity of individuals who are emotionally or mentally disturbed.

Committee on Health Programs for Hospital Personnel.—This Joint Committee of the American Hospital Association and the American Medical Association (represented by the Council on Industrial Health) has completed its "Guiding Principles for an Occupational Health Program in a Hospital Employee Group," and the Committee has now been discharged. The Guide has been approved by both parent groups and was published in the Feb. 15, 1958, issue of THE JOURNAL as well as in *Hospitals*, the Journal of the American Hospital Association. This might pave the way to preparing occupational health guides for other special groups, such as the petroleum, steel, and aviation industries.

Committee on Health Education in Industry.—The Committee studied the matter of health education in industry and reported that it felt that the A. M. A. could not furnish health education materials to millions of workers, and that the Council could use the services of the Bureau of Health Education. The Council accepted the report and discharged the Committee, with the feeling that it had not had such ambitious plans in mind for the Committee. It was felt that perhaps the matter could again be taken up later, or that some one might be added to the staff with abilities in the area of industrial health education.

Council Exhibits and Film

The Council on Industrial Health exhibit entitled "Hazards of Solvents at Home—on the Job" was displayed at the Oklahoma State Medical Society meeting at Oklahoma City during the past year. Plans are now being made to build another Council exhibit. The Council continued to investigate the possibilities of having a film on occupational health, but nothing definite has as yet been advanced.

Staff Activities

During the past year thousands of copies of reprints pertaining to occupational health were supplied to industrial physicians, general practitioners, nurses, and other interested parties. In response to numerous requests from medical and nursing schools, Council publications have been furnished in quantities for use in occupational medicine and nursing instruction. Hundreds of inquiries were answered, some requiring a great deal of literature research. These inquiries concerned a large number of subjects, such as occupational health programs, industrial nursing, industrial hygiene, job health hazards, job and highway safety, physical examination programs, aviation medicine, and preventive medicine in general. Members of the Council and members of the Council's various committees were extremely helpful in providing information for many of the inquiries.

A great deal of staff time was spent in connection with committee activities. Several Council Bulletins were published for the information of its members, and a history covering the Council's activities of the past ten years was prepared.

Joint Activities with A. M. A. Groups

The Council on Industrial Health continued its cooperative efforts with other groups within the A. M. A. In addition to the aforementioned joint activities with the Council on Mental Health, the Council on Industrial Health worked closely with the Committee on Toxicology of the Council on Drugs and with the Council on Medical Service.

The Council on Industrial Health also worked with the Council on Rural Health and occasionally with almost every one of the A. M. A.'s councils, bureaus, and committees. It also contributed staff members' time to staffing A. M. A. Committees and Joint Council Committees.

Cooperation and Liaison with Other Groups

Members of the Council and staff have assisted the American Board of Preventive Medicine in examining candidates for certification in occupational medicine. It has had liaison with approximately 30 other societies, associations, or groups outside of the structure of the A. M. A.

Future Plans of the Council

The Council on Industrial Health has asked for permission to set up a Committee for the Classification of the Pneumoconioses.

The plans for a "Primer" for occupational health programs were put aside for the time being. The Council agreed that such a primer was needed to answer requests for help and guidance from physicians contemplating the establishment of occupational health programs, but that the variety of such programs is so great that the preparation of a primer will require a lot more thought and study. In the meantime, a general letter was prepared as a format to use in writing individualized answers.

The Council plans a comprehensive study of the scope of its future activities. It plans to reactivate and revitalize its committees which have not been active and which are still needed. Within the time available to its limited staff and very busy committee members, the Council will attempt to increase the amount of work its committees turn out.

The Council intends to take stock of its position in the A. M. A. organizational structure in order to see where it can improve its liaison with other councils and committees within the A. M. A. and with outside individuals and organizations interested in occupational health.

The Council intends to evaluate its public relations within its special fields of activity so that more industrial and other interested personnel know of, and make use of, the facilities and knowledge of the Council.

The Council will try, especially, to activate and to make more effective, the Joint Conference with Chairmen of State Medical Society Committees on Industrial Health. It will continue to devote efforts to improving its Annual Congress on Industrial Health.

COUNCIL ON NATIONAL DEFENSE

This report covers the activities of the Council on National Defense for the period July 1, 1957-June 30, 1958.

Meetings and Administrative Actions

During the period covered, the Council and each of its two Committees held two regular meetings. The Council met in Chicago on Oct. 27, 1957, and on May 11, 1958; the Committee on Military Medical Affairs met in Washington, D. C., on Oct. 9-11, 1957, and in Chicago on May 10, 1958; and the Committee on Civil Defense met in Atlanta on Oct. 5-6, 1957, and in Dallas on March 8-9, 1958.

The Executive Committee and other members of the Council met during the Association's 1957 Clinical Session in Boston and its 1958 Annual Meeting in San Francisco. In addition, during the reporting period, Council and Committee members, including the Secretary of the Council, participated in a number of meetings with officials of federal government agencies, state medical societies, and various allied medical and health groups at which problems in the fields of military medicine and civil defense were discussed and views exchanged.

At the 1957 Philadelphia Clinical Session, the Board of Trustees re-elected Dr. Reuben A. Benson of Bremerton, Wash., and Dr. Perrin H. Long of Brooklyn to Council membership for a five-year term to expire Dec. 31, 1962.

Military Medical Activities

At the Washington, D. C., meeting, the Committee on Military Medical Affairs was briefed on various military medical subjects and on organizational and administrative matters within the medical services of the military departments and the U. S. Public Health Service. In separate meetings, the Committee met with Surgeon General Leroy E. Burney, U. S. Public Health Service; Deputy Surgeon General James P. Cooney, U. S. Army, representing Surgeon General Silas B. Hays; Deputy Surgeon General Bruce E. Bradley, U. S. Navy, representing Surgeon General B. W. Hogan; Surgeon General Dan C. Ogle, U. S. Air Force; Dr. Frank B. Berry, Assistant Secretary of Defense (Health and Medical); Dr. Elmer Hess, Chairman, Health Resources Advisory Committee, Office of Defense Mobilization; and Dr. W. Palmer Dearing, Assistant Director for Health, Office of Defense Mobilization.

At these meetings the federal government representatives outlined the organizational structure, authority, responsibility, and functions of their agencies in medical and health matters and discussed with the Committee some of the problems in their respective areas.

The plan to schedule at least one of its two annual meetings in Washington, D. C., has permitted the Committee on Military Medical Affairs to meet with the top level medical representatives of the several Federal agencies and military departments, thereby promoting friendly discussion of appropriate subjects and maintaining a proper liaison.

The Washington, D. C., executive session of the Committee as well as the Chicago meeting in the spring of 1958 considered and acted upon many matters in the field of military medical affairs. Some of the more important actions are outlined.

Commissioning of Optometrists by the Armed Forces.—In June, 1955, at Atlantic City, the House of Delegates adopted Resolution No. 78 concerning ophthalmologic-optometric relations. Part (3) of the resolving clause of the resolution specifies that the Section on Ophthalmology of the A. M. A. ". . . oppose the commissioning of optometrists as such, by any title, in the Armed Forces, and feel that positive action should be taken to bring about the discontinuance of this practice, and request that the Armed Forces provide full medical eye care for all personnel to the end that no member may be subjected to eye care by nonmedical personnel without direction or supervision by an ophthalmologist . . ."

Again in November, 1956, the House of Delegates reviewed this matter and reaffirmed its position. At the request of the General Manager of the Association, the Council considered this matter and recommended the Board actively support part (3) of Resolution No. 78. The Board approved such action and on Jan. 31, 1958, letters were sent to the Secretary of Defense and the surgeons general of the Army, Navy, and Air Force opposing the commissioning of optometrists because "the diagnosis of disease constitutes the practice of medicine and the professional aspects dealing with the prevention of blindness and the conservation or restoration of vision are problems for medical consideration."

Compensation for Military Physicians.—During the legislative process which culminated in the enactment of Public Law 85-422, approved May 20, 1958, which adjusts the method of computing basic pay for officers and enlisted members of the uniformed services, a reduction of benefits achieved by military medicine under the Medical and Dental Officer Career Incentive Act of 1956 was proposed. It will be recalled that the Cordiner Committee was created in May, 1956, to develop and recommend a program of legislative and administrative measures suitable to attract and retain the combat leadership, scientific, professional, technical, and management skills required by our Armed Forces today and in the future.

It is the Association's view that the special pay provisions of the 1956 Act is largely a method of equalizing earnings to compensate for the long and expensive medical education and the resultant delay in earnings to the medical doctor. It was proposed that the special pay received by medical officers of the Armed Forces be reduced by as much as $100 to $150 monthly in the groups of the most experienced physicians. The proposed reduction would not have resulted in decreased compensation for any medical officer but undoubtedly would have had an adverse effect on the attraction and retention of qualified physicians for the military services. For this reason, the Association in opposition to the proposed reduction made its views known to the Congress.

The Association's position was accepted by Congress and thus prevailed in this matter. Public Law 85-422 did not alter the incentive pay provisions of the Medical and Dental Officer Career Incentive Act of 1956.

Extension of "Doctor-Draft" Act.—In response to the request of the Assistant Secretary of Defense (*Health and Medical*), the Association, in June, 1958, made its position known with respect to the extension of the special provisions of the Universal Military Training and Service Act applicable to medical, dental or allied specialists. This legislation, Public Law 85-62, expires June 30, 1959.

The Assistant Secretary was advised that the Association believes that physicians should be registered and classified in the same manner as other citizens in the same age group;

deferred for educational purposes in the same manner as other registrants; and called to active duty or inducted under the same general provisions as other registrants deferred for educational purposes.

No information was presented to the Association which warranted a change in the views presented to the Congress at the time the bill which became Public Law 85-62 was being considered. At that time, in June, 1957, the Association recommended that "the discriminatory and undemocratic legislation known as the Doctor Draft Act be terminated at the present expiration date, June 30, 1957 . . . (however,) if the demands for the defense and security of our nation are such that, in the opinion of Congress, it is necessary to have a Universal Military Training and Service Act to maintain the strength of our Armed Forces, then one method to insure a sufficient supply of physicians for the Armed Forces would be to enact (this) legislation . . ." In addition, in regard to specialists, categories, the Association recommended that the word "other" be substituted for the word "allied" wherever it appeared in the proposed legislation. This proposal was not adopted by the Congress.

Participation in Local Medical Society Affairs by Physicians in Federal Service.—Because of the variance in local and state society rules and regulations and the frequent change of assignments of medical officers of the several services there is no simple or practical manner in which the Council or its Committee on Military Medical Affairs can implement Resolution No. 29 of the 1957 Philadelphia Clinical Session of the House of Delegates, by assisting in increasing participation of physicians, engaged in Federal medical services, in the affairs of local medical societies. The Reference Committee on Medical Military Affairs at the June, 1958 Annual Meeting in San Francisco urged the members of the House of Delegates to stimulate interest in such participation in their own state and county societies by the best locally acceptable plan.

Reorganization of the Department of Defense.—During several months of the reporting period covered by this annual report, the Congress and the Executive branch of the Government were concerned with the proposed reorganization of the Department of Defense. The Council and its Committee followed the developments of this legislation very closely and kept the General Manager and the Board advised as to the status thereon. Inasmuch as the Association understood that in the reorganization it was contemplated that the position of Assistant Secretary of Defense (Health and Medical) would be downgraded to a position of Assistant to the Secretary, representatives of the Association on several occasions presented its views in vigorous opposition to both the Congress and the Executive branch at the highest levels. In addition, the Chairman of the Council's Committee on Military Medical Affairs testified at hearings on the proposal before the U. S. Senate Committee on Armed Services.

The Association believes that it is in the best interests of the national security, the military medical services and the provision of the best possible health services to the personnel of the Armed Forces that the position of Assistant Secretary of Defense (Health and Medical) be maintained in the Department of Defense with a civilian physician appointed to this position with the advice and consent of the Senate. Experience has clearly demonstrated the need and effectiveness of the Assistant Secretary in the formulation of military medical policy and programs, both administrative and military, of the Department of Defense. Moreover, the incumbent of this position, because of his rank, has received the respect of his opposite numbers in the highest circles in our own government, foreign governments and in the professional and scientific organizations.

To downgrade this position would have a most deleterious effect at all echelons within the defense organization upon the medical and health services of our Armed Forces and upon the morale of military personnel. This would involve medical and health policies and programs at all echelons and command levels throughout the defense organization. The loss of stature and prestige in this position would be reflected in the inter-agency health programs within our own government and in the medical and health relationships between our government and other governments with which we are allied.

The need for health and medical policy coordination at the highest level in the Department of Defense is undeniable.

Military Veterinary Corps.—Since early in 1956 when action was initiated by the Department of Defense to eliminate the functions performed by military veterinarians, the Council has urged the Association to pursue a course of opposition to the elimination of the corps. In 1956 the House of Delegates voted to oppose any elimination of military veterinarians and in May, 1957, this position was reiterated and reaffirmed by the Association. On Oct. 1, 1957, by directive of the Secretary of Defense, certain functions of the veterinarian corps were ordered transferred to the Department of Agriculture and military veterinarians were to be released from active duty, transferred or reassigned. At the request of the Council, the Association sent a letter on Oct. 16, 1957, to Secretary McElroy requesting that the Oct. 1 directive be reconsidered because such action may endanger the health of military personnel. The implementation of the directive was delayed to permit a full study of the subject. The fact that this directive has not been put into effect to date coupled with the fact that, under the Department of Defense Reorganization Act of 1958, it will be more difficult for the Secretary, should he so desire, to abolish the veterinary corps than was possible before enactment of the legislation, may indicate that the military veterinary corps will not be abolished as initially contemplated.

Survey of Discharged Medical Personnel.—The Council has continued to conduct an opinion survey among physicians being released from active military service to obtain information on the utilization of physicians and medical staffing conditions in the Armed Forces. From June, 1952 to July, 1958, the Council has distributed 20,222 questionnaires, of which 13,518 were filled out and returned. Summary results of the survey are periodically compiled and published in THE JOURNAL, and copies of the reports are sent to the military departments.

Placement Assistance.—Another continuing program operated by the Council assists physicians being released from active military service by providing information on available civilian medical opportunities. This program has been well received by the participating physicians. Up to July, 1958, the Council has sent letters outlining the program to 18,656 physicians and received 5,186 replies, of which 3,480 were from physicians who requested and were given placement assistance.

Liaison with Physicians on Active Military Duty.—Since January, 1954, the Council has prepared a monthly article for publication in the *United States Armed Forces Medical Journal.* This activity was undertaken to establish and maintain liaison between the Association and physicians in uniform. In this reporting period, these articles have covered such subjects as the summary of survey reports of physicians leaving military service, activities of the AMA councils, reports on proposed and enacted legislation of the 85th Congress, problems of the aging, report on actions at the Association's Annual Meeting and Clinical Session, the Asian influenza epidemic, the revisions of the Principles of Medical Ethics, and medical education of Armed Forces personnel.

Medical Civil Defense Activities

In the fall of 1957, the Council's Committee on Civil Defense, recognizing the need for closer and more effective liaison on medical civil defense matters at state, regional, and national levels, initiated the practice of meeting in each of the seven Federal Civil Defense Administration Regions.

Two-day meetings are held. On the first day the Committee meets with the executive secretary of the medical society of each state in the region, the chairman of each state society's emergency medical service committee, the chairman of the committee on civil defense of the woman's auxiliary to each state society, and the FCDA regional medical officer. The second day is devoted to an executive session meeting of the Committee.

The two regional meetings thus far have been very successful. The exchange of ideas and information and the discussion of common problems at such meetings have proved to be most helpful in the coordination of medical civil defense efforts. They have also stimulated further action at state and local society level.

The first regional meeting was held in FCDA Region III in Atlanta, Ga., in October, 1957. This region comprises the states of Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina, and Tennessee. The second meeting was held in Dallas, Texas, in FCDA Region V in March, 1958. The states of Arkansas, Louisiana, New Mexico, Oklahoma, and Texas are in this region.

By means of these meetings, as well as meetings with FCDA and the officials of other federal government agencies, effective liaison is maintained by the Committee on Civil Defense at state and national levels. In addition, some of the other more important accomplishments in the field *of medical civil defense activities follow.*

Central Repository of Medical Credentials.—In September, 1957, the World Medical Association requested the endorsement of the American Medical Association of the proposal for a Central Repository of Medical Credentials. The proposal anticipates a service to assure physicians throughout the world who avail themselves of the service that they always will be able to prove themselves medically trained and fully accredited to practice medicine. The Board of Trustees in October, 1957, favorably received the recommendation of the Council and approved in principle the idea of a Central Repository for Medical Credentials and recommended that the World Medical Association do all possible to implement the proposal. Later, at the Annual Meeting in San Francisco, the Board voted to request the WMA, United States Committee, Inc. to take complete charge of all procedures connected with the utilization of the Repository by physicians of the United States. The Council has offered to assist the WMA in every way possible to acquaint United States physicians with the facilities available through the central repository and its offer has been accepted.

Proposed FCDA Delegation of Certain Responsibilities for Civil Defense Health Services.—In January, 1958, the FCDA advised the Association that a further assignment of civil defense health services from the FCDA to the Department of Health, Education, and Welfare, for discharge by the Public Health Service, was being considered. The Association's concurrence in the principle of the proposed delegation was requested prior to the initiation of formal negotiations between the FCDA and the Department of HEW.

Upon initial review of the proposed delegation, the Council and its Committee on Civil Defense were disturbed with the manner of the delegation where, in planning a nationwide health and medical care program, there was no clear provision *for the active participation of the states,* political subdivisions, and other organizations and agencies concerned with the health and medical care of the population surviving an enemy attack on the United States. However, at a meeting of the Committee in April, 1958, in Washington, D. C., *with FCDA and USPHS officials,* the Association was assured that the maximum use of all resources at local, state, and national levels was needed and that the support, advice, and participation of the political entities and health and medical groups will be requested *as it was absolutely essential for such groups to assist in* the planning features of the program.

In view of this clarification, the FCDA was advised in June that the Association concurs in the principle of the proposed delegation provided it is specified that the states, local political subdivisions thereof, and other organizations and agencies concerned with the health of the population surviving an enemy attack on the United States will be afforded an opportunity to participate actively in and otherwise contribute to the planning, preparation, and implementation of the contemplated nationwide health and medical care program designed to utilize nonfederal facilities and resources.

Elevation in FCDA of Health and Medical Affairs Position.—In June, 1954, the Association's House of Delegates adopted a resolution requesting the Administrator of the FCDA to re-examine the position of the Health Division and to elevate that Division to a stature commensurate with its obligations and responsibilities. The health and medical aspects of federal civil defense planning have never occupied the authority, responsibility, and organizational status they deserve and, for a number of years, the Council has urged and the Association has made strong representa*tions to elevate the Health Office of FCDA.* Under a reorganization plan effective Nov. 1, 1957, the Health Office of FCDA was abolished and the health and medical activities of that office were fragmentized throughout the new organizational structure of FCDA. On Nov. 7, 1957, Dr. *Hugh H. Hussey Jr., Dr. Harold C. Lueth, and* Association staff members met with Administrator Hoegh to explain the need for a position in the FCDA organizational structure comparable to that in the Department of Defense which has an Assistant Secretary of Defense (Health and Medical) and in the Office of Defense Mobilization which has an Assistant Director for Health. Administrator Hoegh expressed interest in the request and the reasons advanced thereto. In the December, 1957, reorganization of the FCDA the new position of Assistant Administrator, Health and Medical Affairs was created.

Consolidation of FCDA and ODM.—The President's Reorganization Plan No. 1 of 1958 provides that the Federal Civil Defense Administration and the Office of Defense Mobilization be consolidated into a new agency in the Executive Office of the President known as the Office of Defense and Civilian Mobilization.

In June, 1956, the House of Delegates approved the broad objective of strengthening the federal civil defense program but was of the opinion that the method of accomplishment was a matter for determination by the Congress with the advice and assistance of the President and the state governments.

At the time the Plan was before the Senate and House Committees on Government Operations for consideration. the Association advised the Committees that it was concerned with the status, in any federal agency, of the office responsible for medical and health activities in that medical and health activities is one of the most, if not the most, important functions in sustaining the basic concept of national mobilization which is accepted as the "will of the people to resist."

To accomplish this, the Association, in a communication to each Committee, emphasized that the medical and health functions of the civil defense program merit stature and prestige commensurate with the duties and responsibilities which must be assumed. It was pointed out that within ODM there is a position of Assistant Director for Health and a Civilian Resources Advisory Committee and that within FCDA there is a position of Assistant Administrator, Health and Medical Affairs, and that the Association believes that the health and medical functions of both agencies must be maintained at top level in the organization of the proposed Office of Defense and Civilian Mobilization. The *Association expressed its* confidence that the Committees in furtherance of the serious efforts to strengthen the civil defense and mobilization program of our country would give this matter of medical and health affairs the urgent and earnest attention which it merits.

Reorganization Plan No. 1 of 1958 was not rejected by either the Senate or the House and, consequently, under the terms of the Plan, is effective July 1, 1958. The health and medical affairs position in the organizational structure of the new agency had not been established at the time ODCM assumed the functions of FCDA and ODM.

National Medical Civil Defense Conference.—The Council sponsored its sixth annual National Medical Civil Defense Conference in San Francisco on June 21, 1958, prior to the opening of the Association's 107th Annual Meeting. The conference was attended by 229 persons from 40 states, the District of Columbia, Hawaii, Alaska and the Panama Canal Zone. Dr. Gunnar Gundersen, the then President-elect, welcomed the conferees on behalf of the Association.

High ranking officials of the Federal Government presented reports pertaining to governmental activity concerned with civil defense. Among the highlights were the presentations by FCDA Administrator Leo A. Hoegh and Congressman R. Walter Riehlman. Governor Hoegh outlined some of the plans and current concepts of the FCDA while Congressman Riehlman discussed the Congressional program to strengthen our civil defense efforts. Another well received feature of the program was the panel discussion on "The Civil Defense Role of Civilian Physicians in Support of a Civil Emergency" by the deputy surgeon general of the U. S. Public Health Service and the surgeons general of the Departments of the Army and Air Force and the assistant chief for personnel and professional operations in the Bureau of Medicine and Surgery of the Department of the Navy. Various other civil defense topics were presented by physicians who are active in this field in their state and county medical societies.

County Medical Societies Civil Defense Conference.—The eighth annual conference sponsored by the Council for the civil defense organizations of the county medical societies was held in Chicago, Illinois, on Nov. 9-10, 1957. Participating were 155 persons from 34 states, the District of Columbia, and Canada.

The purpose of the conference is to assist medical and health personnel at the local level to plan and train to render the services which will be required in disaster situations or a civil defense emergency. Congresswoman Martha W. Griffiths of Michigan, a member of the House Committee on Government Operations, reported on the status of proposed federal civil defense legislation. Other highlights of the conference were reports on the experience gained through several test operational exercises conducted under simulated disaster conditions, including a critique of the national exercise "Operation Alert." Reports were also given on such subjects as general preparedness planning, hospital operational preparedness, the role of the county medical society, radiological aspects of radiation fall-out, the A. M. A.-FCDA study project, and the A. M. A. program on Asian influenza. In addition, the participants divided into groups to consider problems and recommended courses of action in such emergency situations as a small localized disaster such as a train wreck, plant fire, or collapsed building; a natural disaster such as a flood, hurricane, tornado, or large fire; a disaster in a nature of an epidemic, including bacterial and chemical attack hazards; and large-scale disasters involving radiation hazards such as a reactor plant explosion, sabotage, or enemy attack.

Other Council Activities

Commission on a National Emergency Medical Care Plan.—As outlined in the last annual report, under the terms of a contract with the Federal Civil Defense Administration, the American Medical Association is to "study, develop and recommend the planning, training and operational program needed as a basis for a National Emergency Medical Care Plan for the treatment and care of casualties and noncasualties prior to, during and after a hypothetical 20 megaton ground burst thermonuclear attack upon a selected geographical area or areas in the United States." To facilitate work on this project, the Association created the Commission on a National Emergency Medical Care Plan. The six members designated to serve on the Commission are Dr. Harold C. Lueth, Evanston, Ill., Chairman, and Drs. Carroll P. Hungate, Kansas City, Mo., John F. Burton, Oklahoma City, Robert L. Novy, Detroit, Hanns C. Schwyzer, St. Paul, and Karl R. Lundeberg, Minneapolis. Dr. Earle Standlee of Dallas is the Staff Director.

During this reporting year, representatives of the Association met in Chicago with representatives of several medical and allied organizations to discuss methods of accomplishing the project. Organizations represented were the American College of Surgeons, American Dental Association, American Hospital Association, American Nurses Association, National League for Nursing, American Public Health Association, and American Veterinary Medical Association. As a result of this meeting, three task forces were created. These are Organization, Emergency Medical Care, and Personnel Training and Utilization. At the invitation of the Commission, the above mentioned organizations designated various Task Force representatives.

It is anticipated that the draft report of each Task Force will be submitted to the full Commission sometime in August or September. Concurrently, a report of the field study phase in the Minneapolis-St. Paul area, which was outlined in the last annual report, should be completed by staff members of the Commission. The Commission will submit a report of the completed study project to the Council for its review and referral to the Board of Trustees with its recommendations. It is anticipated that the study project will be completed in November, 1958, in accordance with the terms of the contract.

An interim report on the activities of the Commission was submitted by the Council to the Board of Trustees who, in turn, distributed it to each member of the House of Delegates at the 1958 Annual Meeting of the Association in San Francisco.

The National Space Program.—Because of the enormous medical implications inherent in the national space program, the Council in May, 1958, proposed that the Board of Trustees designate a "responsible agency of the Board" to follow the developments of the several federal government programs. The Council felt that the Association should be prepared to take the initiative in developing sound medical policies relating to the organization, administration, and professional capabilities in such a program.

On May 30 the Board named a committee composed of Drs. Leonard W. Larson, chairman, Richard L. Meiling, and Harold C. Lueth to study this subject and report to the Board. At its meeting in June in San Francisco, the Board designated an *Ad Hoc* Committee on Aeronautics and Space with Dr. Larson, chairman, and Drs. Meiling and Lueth as members to advise the Board on the evolution of the government agencies and legislation affecting them in the area of aeronautics and space. Staffing of the Committee will be undertaken by the Council on National Defense.

A. M. A. Asian Influenza Program.—In the fall of 1957, the United States experienced the most extensive influenza epidemic in 40 years. Samplings taken by the U. S. National Health Survey showed that more than 80 million Americans suffered from illness of the upper respiratory tract between July 1 and Dec. 1, 1957, of such severity that they had to spend one or more days in bed.

On June 20, 1957, following several informal meetings between representatives of the Association and the U. S. Public Health Service, the Council's Committee on Civil Defense was designated a Special Committee on Influenza.

The Special Committee, augmented by Drs. Hugh H. Hussey Jr. and James Z. Appel representing the Board, launched a nationwide preparedness program to combat an Asian influenza epidemic. Recognizing the urgent need for sound medical plans and an effective operational organization, as well as advice to the general public as to what to expect and what to do, the A. M. A. program consisted of an operational and an informational phase.

Nine days later, on June 29, packets of informational and scientific material were mailed to all state and county medical societies, members of the House of Delegates, state presidents, chairmen of state emergency medical service committees, and national officers of allied medical and health associations. The medical profession was alerted and urged to take appropriate steps to have stand-by plans and precautionary measures in readiness in each community. Again on Sept. 29, packets of up-to-date material were distributed to these groups.

A series of articles was published in a special column of The Journal to provide the medical profession with historical and scientific data so that the disease could be recognized immediately and properly treated. *Today's Health* carried informational material. Several A. M. A. news releases, as well as the *Secretary's Letter*, were devoted to the Asian influenza story. A. M. A. representatives appeared on radio and TV programs and radio and television spots with information on home care were prepared and distributed.

During this hectic six-month period, the Committee met several times and its members attended numerous meetings with representatives of the PHS and national medical and health associations.

The Surgeon General of the U. S. Public Health Service, Leroy E. Burney, said, "To me, one of the most significant things about our national experience has been the demonstration of how quickly and effectively our national medical and health resources can mobilize to combat the threat of nationwide illness. The keynote of the whole program, in fact, has been the cooperation of the many toward a single goal. I do not know of another instance in our peacetime history in which so many of the elements of our society, in so short a time, have joined together to identify a health problem, determine the means for its solution, and to work toward resolving it."

To this, the Committee agrees wholeheartedly.

Stand-by Program for Dealing with Mass Immunization or Similar Situations.—In February, 1958, the Board of Trustees authorized the Special Committee on Influenza, in cooperation with the Law Department, to proceed with a study and preparation of a stand-by program for future use in dealing with mass immunization or similar situations.

At the first meeting of the Committee on April 22, the problem to be undertaken was defined and an outline of information to be developed was prepared, including a review of some of the programs of the state and county medical societies. A questionnaire is being prepared by two members of the Committee to elicit the desired information. The other members of the Committee were requested to obtain information from various other groups in regard to their experience during the epidemic and to solicit suggestions with respect to a stand-by program.

Joint Committee on Medical Education for National Defense.—The Council was requested to join with the A. M. A. Council on Medical Education and Hospitals and the Association of American Medical Colleges to serve on the Joint Committee on Medical Education for National Defense. The Joint Committee is composed of representatives and staff secretaries from the three groups mentioned above. The purpose of the Joint Committee is to work together in conference and consultation concerning the role of colleges of medicine in relation to the national defense effort in peace and under wartime conditions. Such topics as the drafting of physicians, essential faculty, acceleration programs, relocation of medical schools, student participation and the operation of MEND programs are a part of the basic problem to be developed.

The Council was represented at a meeting on January 24, 1958, of the Joint Committee by Dr. Richard L. Meiling and the Council secretary. The Council, at its meeting in May, 1958, designated Dr. Meiling and Dr. Harold C. Lueth to serve as representatives of the Council on the Joint Committee.

Publication.—The Council has continued its publication of a *Civil Defense Review* that is distributed bi-monthly. This publication contains information on the latest civil defense developments with emphasis on the medical and health aspects of civil defense. A list of selected recent publications in the civil defense area is also included. The *Civil Defense Review* is sent to over 1,750 persons and groups, including the chairmen and members of the emergency medical service committees of the state medical societies and the woman's auxiliary.

During the reporting year, the Council also published in The Journal and other similar publications selected articles and addresses on the medical aspects of civil defense by persons prominent in the field.

The Council has continued to distribute informational material on the medical aspects of civil defense, medical planning for civil defense and a bibliography of pamphlets, articles, and books in this field.

COUNCIL ON SCIENTIFIC ASSEMBLY

This report includes a summary of the activities of the Council on Scientific Assembly, including the Clinical Meeting in Philadelphia and the Annual Meeting in San Francisco, as well as a review of the motion picture and medical television work.

Council Meetings

The Council on Scientific Assembly has recognized the evolution through which the meetings of the American Medical Association have passed and will continue to pass, and is looking forward to new developments. With this in mind, the Council held four full meetings and in addition conferred with other groups eight times during the year. In the interim, the executive committee and subcommittees of the Council were busy.

New Members of Council.—Two new members of the Council were appointed by the Board of Trustees. Dr. J. Arnold Bargen, Rochester, Minnesota, replaced Dr. Charles H. Phifer, deceased, and Dr. Walter Scott, Los Angeles, replaced Dr. James R. McVay whose term expired. Dr. Samuel P. Newman, Denver, was reappointed for a five-year term to succeed himself.

Meetings with Section Secretaries.—Three meetings were held with the Secretaries of the Sections of the Scientific Assembly. At an all day session in Chicago, the program of the San Francisco meeting was discussed. In San Francisco two meetings were held to make preliminary arrangements for the Atlantic City meeting. The vigor with which the Section Secretaries are undertaking their duties and the imagination shown in the development of their programs augers well for the future of the Association.

Meeting with Section Representatives to the Scientific Exhibit.—The Council met with the Section Representatives to the Scientific Exhibit in San Francisco where general arrangements for the Scientific Exhibit were discussed. The Section Representatives are assuming an increasingly large role in the affairs of the Annual Meeting.

Meetings with Section Delegates.—Members of the Council were breakfast guests of the Section Delegates at both the Philadelphia and San Francisco meetings. General policies of Section activities were reviewed with special attention on changes in the Bylaws.

Committee to Evaluate Scientific Sessions.—The Council met twice with the Committee to Evaluate the Scientific Sessions of which Dr. Hugh H. Hussey, Washington, D. C., is Chairman. Numerous suggestions were discussed, several of which were adopted by the Council for improvement in the scientific program.

Liaison Committee of the Medical Section of the American Drug Manufacturers Association.—The Medical Section of the American Drug Manufacturers Association has been acutely aware of incidents in the Scientific Exhibit which amounted to advertising of certain products. At the request of the Council, a liaison committee was appointed, consisting of Dr. W. D. Snively, Mead Johnson & Co., Evansville, Ind., chairman; Dr. Edward Henderson, Schering Corporation, Bloomfield, N. J.; Dr. John Henderson, Johnson and Johnson, New Brunswick, N. J., Dr Edwin B. McLean, Cutter Laboratories, Berkeley, Calif., and Dr. Clayton G. Weigand, Eli Lilly & Co., Indianapolis. Representatives of this committee met with the Council in San Francisco where future cooperation between the two groups was initiated.

Trans-Atlantic Conferences.—A request was received from the British Medical Association for a Trans-Atlantic conference between the Twelfth Clinical Meeting of the American Medical Association in Minneapolis and the first Clinical Meeting of the British Medical Association in Southampton, which will be held the same week. The Council on Scientific Assembly approved the venture. Dr. Walter Hedgcock, Assistant Secretary of the British Medical Association, met with the Council in San Francisco and details of the Conference were arranged.

Japan Medical Conference.—A request was received from Dr. Tomio Ogata, Tokyo, for certain exhibits and motion pictures from the San Francisco meeting to be shown at the 15th General Assembly, Japan Medical Congress, Tokyo, in 1959. The request also included a provision that two members of the Council staff attend the meeting to supervise the demonstrations. The Board of Trustees approved the project provided there was no cost to the American Medical Association. Dr. Ogata met with the Council in San Francisco to implement the venture. Methods of financing the project are being investigated.

Traveling Exhibits.—A proposal was received from the Purdue Frederick Co., New York, to select certain of the exhibits at the Annual Meeting for a "traveling exhibit" to be shown to the medical profession in the United States and Canada. The Council, after much consideration, voted not to accept the offer.

Exhibits on Film.—Authorization was given to Lakeside Laboratories to continue the project of "Exhibits on Film," whereby features in the Scientific Exhibit would be made available to medical schools and hospital staffs.

Awards in the Scientific Exhibit.—The Council voted to give more publicity to the awards made in the Scientific Exhibit, with a request that the medals be awarded to the recipients at the Inaugural Meeting on Tuesday night. This was impossible at the San Francisco meeting, but the gold medals were presented to the recipients on the television program for the public on Wednesday night.

Grand Rounds.—A request was received from the Upjohn Company, Kalamazoo, Mich., to show by closed circuit television some of the highlights of the Annual Meeting to medical audiences in Boston, Chicago, Cleveland, Kalamazoo, Philadelphia, and New York. The Council approved the venture, which was carried out most successfully.

Audiovisual Conference.—Members of the Council attended a conference called by the Ford Foundation, at the instigation of the Section on Military Medicine, to discuss methods by which more use could be made of audiovisual aids in Section meetings. Numerous suggestions were made, some of which will be incorporated in the program of the Annual Meeting in 1959.

Association for Research in Ophthalmology.—At the request of the Board of Trustees, the Council voted to continue the meetings of the Association for Research in Ophthalmology as part of the program of the Annual Meeting at San Francisco.

National Science Fair.—A committee of the Council attended the National Science Fair in Flint, Mich., selecting four exhibits for A. M. A. awards. Two of these, with the high school students, were brought to the Annual Meeting in San Francisco where the exhibits were shown in the Scientific Exhibit. The project was sponsored by the Department of Public Relations.

Student A. M. A. Exhibits.—The Council approved a request from the Student American Medical Association for a project to be financed by Lakeside Laboratories, Milwaukee, whereby two exhibits would be selected at the Student A. M. A. meeting for showing at the annual A. M. A. meeting. One exhibit was presented in San Francisco from the medical student group and one from the intern-resident group.

Section Centennials.—The Council noted the fact that seven Sections of the Scientific Assembly would observe their centennials in 1959. Preliminary arrangements were made for this occasion with special programs by the Sections concerned.

Philadelphia Clinical Meeting

The 11th Clinical Meeting in Philadelphia will be remembered as the year of the blizzard, making travel to and from Convention Hall difficult. Considering the conditions, however, attendance was good and for those fortunate enough to get to the meeting, the program was excellent. All scientific activities were held in Convention Hall, with all activities in close proximity to each other.

There were 67 lectures and 21 panels and symposiums presented in four meeting rooms simultaneously. The five medical schools in Philadelphia furnished an abundance of interesting material.

Color television, carried by closed circuit from Lankenau Hospital, was outstanding. Each morning wet clinics were presented and each afternoon there were panel discussions. A two-way telephone hookup made discussion easy between panelists and audience. Color television was presented through the cooperation of Smith, Kline & French Laboratories, Philadelphia.

The motion picture program consisted of the best films from the United States and foreign countries. Thirty titles were shown during the week, with sustained interest during the entire time. In addition to the daytime program, there was an evening program, consisting of a premiere showing of the latest March of Medicine Television program, "M.D. International," presented in cooperation with the Smith, Kline & French Laboratories, Philadelphia.

The Scientific Exhibit included continuous demonstrations in 120 booths. Several special features were of outstanding interest—the Special Exhibit on Fractures with Dr. Ralph G. Carothers, Cincinnati, as chairman; the manikin demonstrations on Problems of Delivery, under the guidance of Dr. Thaddeus L. Montgomery, Philadelphia; and the Special Exhibit on the History of Medicine in Philadelphia with Dr. Nicholas Padis, Philadelphia, as chairman.

The program included the names of 624 participants, of whom 288 were from Philadelphia. The lecture and color television programs were presented largely by the Philadelphia group, while motion pictures and scientific exhibits came from all over the United States.

The Association is indebted to members of the Local Committee on Arrangements for a smooth running meeting. The efforts of all contributors resulted in an excellent scientific program.

The Special Committee, augmented by Drs. Hugh H. Hussey Jr. and James Z. Appel representing the Board, launched a nationwide preparedness program to combat an Asian influenza epidemic. Recognizing the urgent need for sound medical plans and an effective operational organization, as well as advice to the general public as to what to expect and what to do, the A. M. A. program consisted of an operational and an informational phase.

Nine days later, on June 29, packets of informational and scientific material were mailed to all state and county medical societies, members of the House of Delegates, state presidents, chairmen of state emergency medical service committees, and national officers of allied medical and health associations. The medical profession was alerted and urged to take appropriate steps to have stand-by plans and precautionary measures in readiness in each community. Again on Sept. 29, packets of up-to-date material were distributed to these groups.

A series of articles was published in a special column of THE JOURNAL to provide the medical profession with historical and scientific data so that the disease could be recognized immediately and properly treated. *Today's Health* carried informational material. Several A. M. A. news releases, as well as the *Secretary's Letter*, were devoted to the Asian influenza story. A. M. A. representatives appeared on radio and TV programs and radio and television spots with information on home care were prepared and distributed.

During this hectic six-month period, the Committee met several times and its members attended numerous meetings with representatives of the PHS and national medical and health associations.

The Surgeon General of the U. S. Public Health Service, Leroy E. Burney, said, "To me, one of the most significant things about our national experience has been the demonstration of how quickly and effectively our national medical and health resources can mobilize to combat the threat of nationwide illness. The keynote of the whole program, in fact, has been the cooperation of the many toward a single goal. I do not know of another instance in our peacetime history in which so many of the elements of our society, in so short a time, have joined together to identify a health problem, determine the means for its solution, and to work toward resolving it."

To this, the Committee agrees wholeheartedly.

Stand-by Program for Dealing with Mass Immunization or Similar Situations.—In February, 1958, the Board of Trustees authorized the Special Committee on Influenza, in cooperation with the Law Department, to proceed with a study and preparation of a stand-by program for future use in dealing with mass immunization or similar situations.

At the first meeting of the Committee on April 22, the problem to be undertaken was defined and an outline of information to be developed was prepared, including a review of some of the programs of the state and county medical societies. A questionnaire is being prepared by two members of the Committee to elicit the desired information. The other members of the Committee were requested to obtain information from various other groups in regard to their experience during the epidemic and to solicit suggestions with respect to a stand-by program.

Joint Committee on Medical Education for National Defense.—The Council was requested to join with the A. M. A. Council on Medical Education and Hospitals and the Association of American Medical Colleges to serve on the Joint Committee on Medical Education for National Defense. The Joint Committee is composed of representatives and staff secretaries from the three groups mentioned above. The purpose of the Joint Committee is to work together in conference and consultation concerning the role of colleges of medicine in relation to the national defense effort in peace and under wartime conditions. Such topics as the drafting of physicians, essential faculty, acceleration programs, relocation of medical schools, student participation and the operation of MEND programs are a part of the basic problem to be developed.

The Council was represented at a meeting on January 24, 1958, of the Joint Committee by Dr. Richard L. Meiling and the Council secretary. The Council, at its meeting in May, 1958, designated Dr. Meiling and Dr. Harold C. Lueth to serve as representatives of the Council on the Joint Committee.

Publication.—The Council has continued its publication of a *Civil Defense Review* that is distributed bi-monthly. This publication contains information on the latest civil defense developments with emphasis on the medical and health aspects of civil defense. A list of selected recent publications in the civil defense area is also included. The *Civil Defense Review* is sent to over 1,750 persons and groups, including the chairmen and members of the emergency medical service committees of the state medical societies and the woman's auxiliary.

During the reporting year, the Council also published in THE JOURNAL and other similar publications selected articles and addresses on the medical aspects of civil defense by persons prominent in the field.

The Council has continued to distribute informational material on the medical aspects of civil defense, medical planning for civil defense and a bibliography of pamphlets, articles, and books in this field.

COUNCIL ON SCIENTIFIC ASSEMBLY

This report includes a summary of the activities of the Council on Scientific Assembly, including the Clinical Meeting in Philadelphia and the Annual Meeting in San Francisco, as well as a review of the motion picture and medical television work.

Council Meetings

The Council on Scientific Assembly has recognized the evolution through which the meetings of the American Medical Association have passed and will continue to pass, and is looking forward to new developments. With this in mind, the Council held four full meetings and in addition conferred with other groups eight times during the year. In the interim, the executive committee and subcommittees of the Council were busy.

New Members of Council.—Two new members of the Council were appointed by the Board of Trustees. Dr. J. Arnold Bargen, Rochester, Minnesota, replaced Dr. Charles H. Phifer, deceased, and Dr. Walter Scott, Los Angeles, replaced Dr. James R. McVay whose term expired. Dr. Samuel P. Newman, Denver, was reappointed for a five-year term to succeed himself.

Meetings with Section Secretaries.—Three meetings were held with the Secretaries of the Sections of the Scientific Assembly. At an all day session in Chicago, the program of the San Francisco meeting was discussed. In San Francisco two meetings were held to make preliminary arrangements for the Atlantic City meeting. The vigor with which the Section Secretaries are undertaking their duties and the imagination shown in the development of their programs augers well for the future of the Association.

Meeting with Section Representatives to the Scientific Exhibit.—The Council met with the Section Representatives to the Scientific Exhibit in San Francisco where general arrangements for the Scientific Exhibit were discussed. The Section Representatives are assuming an increasingly large role in the affairs of the Annual Meeting.

Meetings with Section Delegates.—Members of the Council were breakfast guests of the Section Delegates at both the Philadelphia and San Francisco meetings. General policies of Section activities were reviewed with special attention on changes in the Bylaws.

Committee to Evaluate Scientific Sessions.—The Council met twice with the Committee to Evaluate the Scientific Sessions of which Dr. Hugh H. Hussey, Washington, D. C., is Chairman. Numerous suggestions were discussed, several of which were adopted by the Council for improvement in the scientific program.

Liaison Committee of the Medical Section of the American Drug Manufacturers Association.—The Medical Section of the American Drug Manufacturers Association has been acutely aware of incidents in the Scientific Exhibit which amounted to advertising of certain products. At the request of the Council, a liaison committee was appointed, consisting of Dr. W. D. Snively, Mead Johnson & Co., Evansville, Ind., chairman; Dr. Edward Henderson, Schering Corporation, Bloomfield, N. J.; Dr. John Henderson, Johnson and Johnson, New Brunswick, N. J.; Dr. Edwin B. McLean, Cutter Laboratories, Berkeley, Calif., and Dr. Clayton G. Weigand, Eli Lilly & Co., Indianapolis. Representatives of this committee met with the Council in San Francisco where future cooperation between the two groups was initiated.

Trans-Atlantic Conferences.—A request was received from the British Medical Association for a Trans-Atlantic conference between the Twelfth Clinical Meeting of the American Medical Association in Minneapolis and the first Clinical Meeting of the British Medical Association in Southampton, which will be held the same week. The Council on Scientific Assembly approved the venture. Dr. Walter Hedgecock, Assistant Secretary of the British Medical Association, met with the Council in San Francisco and details of the Conference were arranged.

Japan Medical Conference.—A request was received from Dr. Tomio Ogata, Tokyo, for certain exhibits and motion pictures from the San Francisco meeting to be shown at the 15th General Assembly, Japan Medical Congress, Tokyo, in 1959. The request also included a provision that two members of the Council staff attend the meeting to supervise the demonstrations. The Board of Trustees approved the project provided there was no cost to the American Medical Association. Dr. Ogata met with the Council in San Francisco to implement the venture. Methods of financing the project are being investigated.

Traveling Exhibits.—A proposal was received from the Purdue Frederick Co., New York, to select certain of the exhibits at the Annual Meeting for a "traveling exhibit" to be shown to the medical profession in the United States and Canada. The Council, after much consideration, voted not to accept the offer.

Exhibits on Film.—Authorization was given to Lakeside Laboratories to continue the project of "Exhibits on Film," whereby features in the Scientific Exhibit would be made available to medical schools and hospital staffs.

Awards in the Scientific Exhibit.—The Council voted to give more publicity to the awards made in the Scientific Exhibit, with a request that the medals be awarded to the recipients at the Inaugural Meeting on Tuesday night. This was impossible at the San Francisco meeting, but the gold medals were presented to the recipients on the television program for the public on Wednesday night.

Grand Rounds.—A request was received from the Upjohn Company, Kalamazoo, Mich., to show by closed circuit television some of the highlights of the Annual Meeting to medical audiences in Boston, Chicago, Cleveland, Kalamazoo, Philadelphia, and New York. The Council approved the venture, which was carried out most successfully.

Audiovisual Conference.—Members of the Council attended a conference called by the Ford Foundation, at the instigation of the Section on Military Medicine, to discuss methods by which more use could be made of audiovisual aids in Section meetings. Numerous suggestions were made, some of which will be incorporated in the program of the Annual Meeting in 1959.

Association for Research in Ophthalmology.—At the request of the Board of Trustees, the Council voted to continue the meetings of the Association for Research in Ophthalmology as part of the program of the Annual Meeting at San Francisco.

National Science Fair.—A committee of the Council attended the National Science Fair in Flint, Mich., selecting four exhibits for A. M. A. awards. Two of these, with the high school students, were brought to the Annual Meeting in San Francisco where the exhibits were shown in the Scientific Exhibit. The project was sponsored by the Department of Public Relations.

Student A. M. A. Exhibits.—The Council approved a request from the Student American Medical Association for a project to be financed by Lakeside Laboratories, Milwaukee, whereby two exhibits would be selected at the Student A. M. A. meeting for showing at the annual A. M. A. meeting. One exhibit was presented in San Francisco from the medical student group and one from the intern-resident group.

Section Centennials.—The Council noted the fact that seven Sections of the Scientific Assembly would observe their centennials in 1959. Preliminary arrangements were made for this occasion with special programs by the Sections concerned.

Philadelphia Clinical Meeting

The 11th Clinical Meeting in Philadelphia will be remembered as the year of the blizzard, making travel to and from Convention Hall difficult. Considering the conditions, however, attendance was good and for those fortunate enough to get to the meeting, the program was excellent. All scientific activities were held in Convention Hall, with all activities in close proximity to each other.

There were 67 lectures and 21 panels and symposiums presented in four meeting rooms simultaneously. The five medical schools in Philadelphia furnished an abundance of interesting material.

Color television, carried by closed circuit from Lankenau Hospital, was outstanding. Each morning wet clinics were presented and each afternoon there were panel discussions. A two-way telephone hookup made discussion easy between panelists and audience. Color television was presented through the cooperation of Smith, Kline & French Laboratories, Philadelphia.

The motion picture program consisted of the best films from the United States and foreign countries. Thirty titles were shown during the week, with sustained interest during the entire time. In addition to the daytime program, there was an evening program, consisting of a premiere showing of the latest March of Medicine Television program, "M.D. International," presented in cooperation with the Smith, Kline & French Laboratories, Philadelphia.

The Scientific Exhibit included continuous demonstrations in 120 booths. Several special features were of outstanding interest—the Special Exhibit on Fractures with Dr. Ralph G. Carothers, Cincinnati, as chairman; the manikin demonstrations on Problems of Delivery, under the guidance of Dr. Thaddeus L. Montgomery, Philadelphia; and the Special Exhibit on the History of Medicine in Philadelphia with Dr. Nicholas Padis, Philadelphia, as chairman.

The program included the names of 624 participants, of whom 288 were from Philadelphia. The lecture and color television programs were presented largely by the Philadelphia group, while motion pictures and scientific exhibits came from all over the United States.

The Association is indebted to members of the Local Committee on Arrangements for a smooth running meeting. The efforts of all contributors resulted in an excellent scientific program.

Annual Meeting—San Francisco

The attendance at the Annual Meeting in San Francisco was the largest ever registered in that City for a meeting of the American Medical Association. The headquarters for scientific activities was located at the Civic Auditorium, but most of the meetings were held in other sections of the city. Attendance at Section meetings, in most instances, was very satisfactory.

The General Scientific Lectures presented on Monday afternoon and Tuesday morning were outstanding, and drew capacity audiences. These were arranged by the Council on Scientific Assembly under the chairmanship of Dr. Samuel P. Newman, Denver. The Goldberger lecture was cancelled because of illness in the family of the speaker.

The 21 Sections of the Scientific Assembly held 58 sessions, in addition to five sessions by the Association for Research in Ophthalmology. On six occasions two Sections met in joint session. There were 31 panel discussions and symposiums, marking the trend away from the essay type of lecture; in fact, most of the talks carried the names of two to five authors. The Section Secretaries are to be commended for the excellent programs which they arranged.

Color television originated at San Francisco Hospital and was carried to Civic Auditorium by closed circuit. Operative surgical panels were shown each morning and clinics each afternoon, under the chairmanship of Dr. John B. Schaupp, San Francisco. The telecasts were presented with the cooperation of Smith, Kline & French Laboratories, Philadelphia.

Motion pictures were presented continuously throughout the week in Civic Auditorium to capacity audiences. There were 64 films covering all phases of medicine, with the author present to discuss the subject in many instances.

Two evening programs were presented. Grand Rounds closed circuit television was carried to seven cities located from Chicago to New York, showing the highlights of the San Francisco meeting, and presenting a clinical session on The Current Therapy of Diabetes, emanating from the University of California School of Medicine. The feature was sponsored by The Upjohn Company, Kalamazoo, Mich. A special evening of motion pictures dealing with "Medicine and the Law" was carried out with the cooperation of Wm. S. Merrell Company. The film was a joint undertaking of the American Medical Association and the American Bar Association.

The Scientific Exhibit in Civic Auditorium featured groups of 295 exhibits from the various Sections of the Scientific Assembly, arranged with the cooperation of the Section Representatives to the Scientific Exhibit. In addition, 27 exhibits were presented as special features. A group of exhibits on arthritis and rheumatism was shown under a committee of which Dr. John R. Sigler, Detroit, was chairman. Perinatal problems were presented with the cooperation of the Sections on Anesthesiology, Pediatrics, and Obstetrics and Gynecology by a committee of which Dr. Hulda E. Thelander, San Francisco, was chairman. The Special Exhibit on Fractures, presented under the auspices of a committee of which Dr. Ralph G. Carothers, Cincinnati, was chairman, was again an outstanding success. The Special Exhibit on Fresh Tissue Pathology was sponsored by the Section on Pathology and Physiology, with Dr. Hamilton R. Fishback, Berkeley, California, chairman. The Special Exhibit on Pulmonary Function was sponsored by the Section on Diseases of the Chest under a committee of which Dr. George R. Meneely, Nashville, Tenn., was chairman. The history of medicine was featured by exhibits presented with the cooperation of Parke Davis and Company, Detroit; E. R. Squibb and Sons, New York, and the Army and Navy under the Section on Military Medicine. Physical examinations of physicians were again sponsored by the Section on General Practice, with the assistance of the X-ray Department, General Electric Company and the Sanborn Company. Dr. Charles E. McArthur, Olympia, Wash., wa chairman. Conferences on diet were presented with the guidance of the Council on Foods and Nutrition of the American Medical Association. Two exhibits from the National Science Fair were presented with the cooperation of the A. M. A. Public Relations Department, while two exhibits from the Student A. M. A. were sponsored by Lakeside Laboratories, Milwaukee.

Credit for attending the meeting was given to acti and reserve officers of the Army, Navy, and Air Force. Similarly, credit in Category I was given by the American Academy of General Practice to its members who were present in San Francisco.

Sixty exhibits received awards, consisting of 6 medals, 22 certificates of merit, and 32 honorable mentions. In addition two certificates of merit were presented for medical illustration and for medical photography. The chairman of the Committee on Awards was Dr. Frank B. Queen, Portland, Ore. In addition, the Section on Urology presented the John Morrissey award and the Section on Ophthalmology an award of $250.

The Council on Scientific Assembly wishes to express its appreciation to the 1,914 participants on the scientific program, as well as to the Section officers and speci committees.

Motion Pictures and Medical Television

Film Library.—The film library has been completely r organized and brought up-to-date with a new card file an numbering system initiated. Film subjects in the libra were also surveyed resulting in the withdrawal of sever out-dated and seldom used films. During the past year, new film subjects were added to the library making total of 954 prints of 188 subjects. Film shipments medical societies, medical schools, hospital staff group individual physicians and television stations numbered 4,67 representing an increase of 577 shipments over the la year. The income from film service charges was $8,456.4 The above shipments do not include the highly specializ films included in the one-print library. These films, numbering in excess of 150 subjects, are made available on on special request by physicians.

Approximately 29% of the film distribution is now devoted to prints placed in the library over the years other bureaus and councils. The decrease noted in t number of prints now in the film library is largely due the withdrawal of subjects placed there by other burea and councils which are now out-dated.

In accordance with the Report of the House of Del gates at the 1957 Philadelphia Meeting, seven outstandi foreign-made films have been added to the film libra and have since enjoyed wide circulation. These films, ma in Czechoslovakia, England, Japan, and Australia, were i cluded in the film program at the Annual Meeting in S Francisco. Consideration is being given also to other f eign-made films which reviewers feel should be ma available to physicians in this country.

Film Reviews.—In cooperation with specialists in vario fields of medicine, surgery and health education, 69 revie of medical and health films were published in THE JOURN and 13 health film reviews were prepared for publicati in *Today's Health*. At the request of the editor of *Toda Health*, the reviews of health films which have appear in that publication in the past have been discontinued.

As a special feature of THE JOURNAL, eight illustrat reviews of outstanding films were also prepared and pu lished. These illustrated film reviews have been very w received as evidenced by the number of letters receiv from physician readers of THE JOURNAL, and also by t large number of reprints which have been ordered a distributed by the authors.

The long term cooperative reviewing project with the Educational Committee of the American Academy of Pediatrics has continued and a catalog is now being prepared which will list approximately 250 films approved and recommended by the committee.

Source File.—Additional Kardex files were added during the year to accommodate the ever-growing film source file. As one of the largest files of films produced for the medical profession, it now contains data on over 4,500 films, including date of production, description, and availability. This source file was used in answering 1,300 requests for film information during the year.

Medical Television.—This department continues to serve as an information center for inquiries on the latest equipment, advances, and use of the television medium as a teaching tool for the medical profession. Cooperation in several open and closed circuit television programs included the Upjohn Company's "Grand Rounds No. 7"; The Merck, Sharp and Dohme program during the Annual Meeting, "The Daily Bulletin of the Air"; and the Smith, Kline & French color television program at both the Annual and Clinical Meetings.

Miscellaneous Activities.—Due to the fact that the Film Council of America is no longer in existence, a special committee on International Non-Theatrical Events to determine United States policy of participation in international film festivals was originated in Washington, D. C. The Director was asked to serve on this Committee, representing the medical and dental fields. The purpose of the Committee is not only to determine policy participation, but also to nominate for showing current and outstanding films produced in this country. Composed of eight representatives in the major areas where films are utilized, the Committee meets in Washington to act in connection with international film events.

Cooperation was extended to the International College of Surgeons in Brussels, Belgium, May, 1958, in organizing its film program. Arrangements were made for the selection and shipment of program films from this country, including 10 from our library.

For the first time in the history of the World Medical Association, a film program will be a part of the 12th General Assembly to be held in Copenhagen, Denmark, August, 1958. The film program was organized by the Director. Films from six countries will be included on the daily programs. A film symposium will also be held on the subject of proctology. In most cases, the authors of the films will be present to appear on the programs. This program is being presented by the World Medical Association in cooperation with the American Medical Association and Johnson & Johnson International.

Two film programs were organized in connection with the International Film Festival to be held in Edinburgh, Scotland, in August. During this meeting the Director will address an audience of health educators and motion picture producers on the subject of "The Use of Health Films in the U. S." At that time, he will show films on the subject of health education for lay audiences, which have been found to be particularly effective in this country. He will also address the faculty of the University of Edinburgh School of Medicine on "Motion Pictures and Television in Medical Education." A special program of professional films selected from this country will be shown at the University.

A film on career opportunities in medicine and health, entitled "Helping Hands for Julie" was completed and premiered during American Hospital Week. This film, produced in cooperation with the American Hospital Association and E. R. Squibb and Sons, was designed to motivate high school students to think in terms of choosing a health career. A special showing was arranged by the Woman's Auxiliary of the A. M. A. during the Annual Meeting in San Francisco. One hundred eighty-five copies of "Helping Hands for Julie" have been deposited by E. R. Squibb and Sons with Association Films, Inc., for distribution to high schools, church groups, and community organizations. The film will be released also for television showings. Requests for 56 television prints are now on file, and 11 requests have been received from schools and institutions which would like to purchase a print for their library.

The Director was asked to repeat a course on problems in basic film production at the American Academy of Orthopedic Surgeons held in New York in February. This special course was initiated at the 1957 Annual Meeting and met with a great deal of popularity. For that reason, the course was expanded and again presented for the benefit of the orthopedic surgeons attending the meeting.

Publications included Review Booklet No. 9 containing all reviews appearing in THE JOURNAL during the calendar year of 1957 as well as a new catalog listing all films available from the film library.

BUREAU OF EXHIBITS

Over the past few years a concerted effort has been made to establish a planned program for the development of exhibits designed for public showing at health fairs, expositions, county and state fairs, and other similar types of gatherings.

Health Exhibits.—The exhibits in this planned program are built around the standard chapters found in many anatomy and physiology textbooks. The wisdom of this act has been demonstrated by actual reports from officers and executives of the state and county medical societies, who are the primary users of the exhibits.

In order to determine to what extent the exhibits are viewed and participated in by visitors, counters and other devices are incorporated in the exhibits. Mechanical counters incorporated in one exhibit, "We See," had 55,346 participants at one exposition and 49,500 at another.

Exhibits added during the past year in the continuance of the planned program include "How We Breathe," "Your Glands," "Your Body," and "Digestion." Others completed during the year were exhibits on: "Poisoning of Children in the Home," "You Can Reduce," "Nutrition Nonsense and Food Quackery," and "Seven Paths to Fitness."

An exhibit on the brain and nervous system has been completed through the blueprint and preparatory stages and is ready for construction. An exhibit on the skin is well advanced.

During the past year it has been necessary to decline 96 requests for the use of Association exhibits for 30 different exhibits. The demands far exceed availability.

The Association has a total of 63 exhibits that are available for loan to state and county medical societies. These exhibits were shown in 30 different states in the United States and the Territory of Hawaii, and at 159 locations, for a total of 967 showing days.

Medical Exhibits.—The medical exhibits of the Association were shown at 6 state medical society meetings and at 12 meetings of groups allied to medicine.

Health Fairs.—State and county medical societies continue to show interest in health fairs. Health fairs and health days were presented this year in Pennsylvania, Oregon, New York, Ohio, Illinois, and planned to continue

Museums.—The Association h

BUREAU OF HEALTH EDUCATION

This report covers the latter half of the 25th and the first half of the 26th year of incumbency of the present Director, who is the fourth individual to hold this position.

Administrative and Personnel

No significant changes occurred in the organization of the Bureau, nor in its personnel. We have had the good fortune to have a very small turnover of clerical staff and our professional staff has remained intact.

Following are the principal areas of emphasis in the work of the Bureau in the year just closed.

Fitness of American Youth

This activity was reported in the 1957 report. The only new features to be recorded now are the holding of a Conference at West Point, Sept. 9-10, 1957, which was attended by the Director of the Bureau in his capacity as a member of the President's Citizens' Advisory Committee on the Fitness of American Youth.

This meeting was much like the one held in June, 1956, at Annapolis. Many of the same individuals were present and the same interests were represented, namely physical education, general education, media of mass communication, athletics, sports, commercial interests, medicine, dentistry, public health, and youth-serving and character-building organizations. Members of this Advisory Committee are appointed as individuals, not as representatives of organizations. Nevertheless, there can be no separation between the interests of these members and their organizational identification in the professions or in business.

The West Point meeting differed from that at Annapolis in that the meeting at West Point was a meeting of the President's Council on Youth Fitness with the Advisory Committee, which according to Executive order of the President, is required once a year. The five cabinet officials who are members of the Council did not appear, with the exception of Secretary Benson, of the Department of Agriculture. The rest was represented by under-secretaries or other designated persons. The meeting consisted largely of discussion groups, with a few summarizing sessions.

In general, the same conclusions were reached as at the Annapolis meeting, namely:

(a) The health status of American youth is essentially good but there are areas where improvement is desirable and a few areas where it is immediately imperative.

(b) The fitness of American youth or of adults, for that matter, embraces not only physical, but mental, moral, spiritual and social fitness.

(c) The greatest apparent lack at this time is in the physical area and, therefore, more attention should be focused on this.

(d) A program of greater activity and less sedentary living, especially for youth, seems desirable to improve the fitness of the nation.

(e) Such a program should be implemented through existing organizations and largely at the local level.

(f) No need exists for a super-agency at the federal level beyond the function of advising, stimulating, and helping to correlate; this function is to be performed

vas built

largely around this theme. The American Medical Association included in its annual meeting program, at San Francisco, a symposium having to do with fitness, athletics, and related interests. Many other agencies are paying increased attention to fitness, and especially to physical fitness and encouragement of activity programs.

Some controversy has developed over the question of promulgating standards. Headed by *Sports Illustrated* magazine, a group of athletes and physical educators, which seems to believe in standards, has pressured the Council to engage in the development and promulgation of standards of fitness to be applied periodically to all young people. This pressure has been countered by opposition from the medical profession, most general educators and a considerable number of physical educators. It is not clear at this writing whether the majority of physical educators favors standards or opposes them. There are several sets of standards in process of development by physical education groups and unquestionably, this topic will be a principal source of discussion, if not contention, at the second meeting of the President's Council on Youth Fitness with the Citizens' Advisory Committee, now scheduled for Sept. 9-10, 1958.

The Bureau has published a pamphlet, drawn from medical literature, on the benefits of exercise, and one giving the perspective which shows that the medical profession has been interested in physical fitness long before the present splurge of public interest. These pamphlets have been distributed to all members of the President's Citizens Advisory Committee, as well as widely in other areas. The one on exercise is being reprinted by the Council and will be made available through the Government Printing Office.

The Journal of the American Medical Association has published two editorials discussing the question of fitness. Many state conferences have been held in which state medical societies have participated. In at least one instance, the state society was alerted, through the offices of the American Medical Association, to a proposed fitness conference to which no representatives of the state medical society had been invited by the state governor.

The program on fitness continues to have the backing of the President of the United States and it will attract a great deal of attention as long as this is so. It offers a tempting opportunity for self-promoters and nonscientific zealots to promulgate their ideas. The members of the President's Council at the cabinet level and the members of the Citizens Advisory Committee need professional support, especially from doctors and educators, in keeping this program on a sane and sensible basis.

During the year, the Vice-President of the United States retired from the chairmanship of the Council and this post was given to the Secretary of the Interior. Other cabinet members who constitute the Council are the Secretary of Defense, the Secretary of Health, Education, and Welfare, the Secretary of Agriculture, and the Secretary of Labor.

Pamphlet Distribution

The number of pamphlets distributed by the Bureau and through the Order Department reached a total of 525,172 during the year covered by this report. This sounds like a considerable number but actually the distribution of our pamphlets is the weakest link in the entire pamphlet operation. We have no sales channels through which quantities of pamphlets can be distributed consistently. At the same time, we have an educational opportunity to keep a pamphlet supply which will be useful to those who seek our help in educational circles and among homemakers.

Questions and Answers

During the 12-month period ending June 30, 1958, we answered a total of 15,968 (16,129) letters. (Last year's figures are in parentheses.) The leading subject of interest was plastic surgery, which brought 2,075 (3,232) requests for information and literature. This was stimulated in part by several articles in consumer publications which mentioned the Bureau as a source of information.

The second highest number of requests was for material on the human body. These totaled 1,883 (472). This subject had not been of primary significance in the past few years. Medical guidance, which was the subject of second greatest interest in the 1956-1957 report, dropped to eighth place.

In third place were 1,780 (863) requests for sex education material. This was in fourth place in the previous report.

The fouth subject of leading interest was nutrition, 1,541 (414). This was believed due at least in part to a new series on nutrition, consisting of 12 articles reprinted from *Today's Health* during the period covered by this report.

Following in order of popularity were safety, 1,200; mental health, 1,066; medical practice, 788; medical guidance, 768; public health, 761; heart, 750; hair and skin, 701; drugs, 646; alcohol, tobacco, and narcotics, 569; communicable diseases, 454; circulatory system, 322; glands, 266; bones, 223; and cancer, 160.

Special mailing of packets of free material to school teachers totaled 6,263 (1,489). The increase is believed to have been due in large part to increased attendance of Bureau personnel at workshops and teachers' conventions. There were 2,858 (2,003) catalogs mailed in response to separate requests.

The *Today's Health* column, "That's a Good Question," contained 107 articles, 81 prepared by the Bureau, 21 by the Council on Foods and Nutrition, and 5 by the American Dental Association.

Loan Collections

Requests for special material to assist physicians who are preparing discussions for lay audiences have remained at a rather constant level. For the current period, these total 20 (14). Since interest is still demonstrated in this service, it is continuing to be made available. Flexibility of our procedure in handling such requests permits its satisfactory operation regardless of volume.

Sources of inquiry for the period ending June 30, 1958, were 18 physicians; 1 county Medical Society; 1 nurse.

Principal interest was in material dealing with mental hygiene, cancer, and safety.

Radio and Television

Radio.—There has been no change in the situation, discussed at length in last year's report, which sees radio continuing to grow in importance despite the popularity of television. The Bureau, therefore, continues to recommend radio coverage on behalf of the Association.

Radio, however, is undergoing extensive changes. There are almost no 30-minute radio broadcasts any more, such as used to constitute the backbone of radio programming. Network radio, likewise, has undergone a great change. In place of the short independent programs, we now have such efforts as Monitor, which runs practically through an entire week-end and consists of brief presentations of numerous and diversified interests. Such programming can be likened to a newspaper page of various articles on a multiplicity of subjects, rather than to a magazine in which articles of considerable length occupy a number of pages.

The smaller radio stations are now devoting their time more and more to news, music and sports. This means a complete rethinking of all radio presentations. For many years we have been successful with 13-program series, 15-minutes each, devoted to a given subject and devised to be broadcast once a week at a specified time. This sort of programming will no longer serve us. We must now recognize the new trend if we are to be heard on radio. This trend is to news, music, and sports and with a strong tendency toward brevity.

We have recognized the new look in radio by changing our techniques for 1958. We did produce two 13-program series which were already in the works in 1957.

All music used on these series, as well as all others, has been cleared at the source. This has been made possible by a special arrangement negotiated with ASCAP (American Society of Composers, Authors and Publishers) by the Marshall Organization. ASCAP controls copyrights on current music and charges a royalty for each performance. This arrangement was impractical for the American Medical Association because our distribution is through county medical societies, and it would have posed a very difficult problem to get an accurate account of how many performances actually were made of any given piece of music used. The Marshall Organization succeeded in making an agreement with ASCAP whereby permission for use of a given piece of music could be paid for in one sum in advance. This has opened for our use the tremendous resources of modern, popular music, whereas previously we had been limited to the classics, or at least to music more than 56 years old; this figure represents the renewable copyright periods. In most instances, in order to be absolutely certain that there would be no infringements, we were compelled to use only the music of composers who had been dead for at least 56 years.

In line with the new trend in radio we launched, on Feb. 1, 1958, an entirely new program format called "Health Magazine of the Air." This is based on the A. M. A.'s health magazine, *Today's Health*. It is a 15-minute narration type of program derived from articles in each issue of *Today's Health* and aired at approximately the time the magazine appears on the newsstands. This program is written by an experienced radio script writer, who receives the advance proofs of the magazine as soon as they are available.

The program is narrated by H. V. Kaltenborn, dean of American news analysts, and well known conservative commentator on politics and world events. Mr. Kaltenborn's characteristically energetic, intelligent, and humorous narrations and commentaries have gained him a world-wide reputation. We have been extremely fortunate in getting his services through the Marshall Organization. Each program includes one or two questions from *Today's Health*, which Mr. Kaltenborn asks and which are answered by the Director of the Bureau.

"Health Magazine of the Air" was distributed at the close of this report year to approximately 500 local radio stations. A postcard survey of the utilization of this program and station reactions brought approximately 150 responses, from which we are able to estimate that the program was aired by from 90 to 95% of the stations receiving it.

Each of these health magazine programs uses one side of a transcription disc. In order not to waste the other side, it was decided to try to supply the stations with so-called spot announcements. These are briefs, ranging from 20 seconds to one minute, which can be used by the station at any time when there is air time to fill. In order to give special interest to these announcements, an effort was made to have them narrated by popular personalities in the theatrical and sports fields. The Marshall Organization was able to get the cooperation, gratis, of the following personalities to make the respective announcements: February, Peggy Wood; March, Henry Fonda; April, Douglas Fairbanks Jr.; May, Ralph Bellamy; June, Patti Page; July, Tyrone Power.

"Health Magazine of the Air" is planned to continue through the calendar year 1958.

Television.—The television story is not so happy. Television is an extremely costly medium. At this time, it is surrounded by a glamour which causes many persons to overestimate its importance and to misinterpret the means for using it.

The Bureau of Health Education has explored many avenues looking toward the development of a successful program in television. An obvious solution and one which was tried early was the preparation of scripts for local use. It was soon found that the local medical society would not use scripts because they had neither the personnel nor the inclination to invest time in television programming; or having such time and inclination, they preferred to do their own programming.

This latter is a wholesome trend and the Bureau tried to be helpful by developing helps for local television which it titled "TV Tested Televisuals." We have a considerable stock of these, including many charts and pictures and a number of three-dimensional models available for loan. A catalog of these materials has been published. Their availability has been widely publicized through the *Secretary's Letter* and other intra-professional channels. Regrettably, they have not been used to the extent to which they could have been useful. They remain available for any medical society which wishes to use them.

Another effort to be helpful to the local medical society was the development of scripts with film. A television program must have something to look at besides the telecaster. A panel of physicians, sitting before a television camera and talking, is merely a radio program on television and it is not justified because of its ineffectiveness and its greater expense. There must be "visuals." Procuring or preparing these is time-consuming and costly. So we tried to prepare scripts with film. These, also widely publicized, have not been used by local medical societies to any appreciable extent.

The Bureau, under the authorization by the Trustees, participated with the Herbert S. Laufman Company, of Chicago, in 1956 in the making of 52 films on baby care, whose wide showing on a commercial basis has previously been reported. During the past year, the Bureau purchased limited rights for the use of 13 of these films by county medical societies, and they have had a considerable currency, namely 1,069 showings. The contract expired as of June 1, 1958, and could not be renewed because of inadequate funds. If this could have been renewed, the films would have had a still wider exposure.

Under special grants from the Board of Trustees, the Bureau has made one 30-minute film which, after several years of showing, has become outdated and is now being retired; this was "Operation Herbert." The Bureau also made 18 5-minute films entitled "What To Do" (until the doctor comes). These films, dating back to previous years, have had a satisfactory distribution through two film-distributing companies on a non-commercial basis and have been shown on non-commercial time. They have accounted for a total of 318 telecasts.

During the year covered by this report, we made two films, each 15 minutes in length, under the general heading of "Emergency Call." One of these was entitled "Out of Step," and dealt with the misadventures of a father who did not appreciate Boy Scout activities, but who got into trouble as a do-it-yourself operator and was given some wholesome lessons by the Boy Scouts. In true soap opera style, he was converted to scouting and along the way, the viewer got some sound information about first aid. The other film was entitled "The Silent Killer," and dealt with the dangers of carbon monoxide, how to avoid them, and what to do if a victim has become asphyxiated. It is too early yet to know how effective the distribution of these films will be but there is every reason to believe that they will be widely used.

The experience of the Bureau indicates more and more that television by the medical profession is essentially a local function. There are numerous good television programs carried out locally by medical societies, mainly in the larger centers, where large memberships and the availability of full-time personnel make possible the carrying of the detailed and heavy responsibilities of remaining continuously on television. The function of the American Medical Association would seem to be that of standing-by with helps, the exploration of new techniques and the distribution of information of a technical character which will be helpful to local physicians and medical societies employing television.

Annual and Clinical Sessions.—The scientific aspects of the annual meeting of the American Medical Association in San Francisco were covered by the Bureau in the usual manner.

The net result of this was a 38-station western network of the Columbia Broadcasting System broadcasting a daily program Sunday through Thursday, plus numerous other local and network appearances on NBC, CBS, and Mutual for a total of 575 network radio programs and 34 local programs. In addition, 21 television programs were arranged, some on film and some for personal appearances. The three major networks, National, Columbia and Mutual, were serviced with film for their news round-ups. The President of the Association, Dr. Gunnar Gundersen, and the Gold Medal Doctor, Dr. Frank H. Krusen, were filmed with sound for the news round-ups. Many of the programs were put on tape or film and scheduled for various stations in the San Francisco bay area after the close of the meeting.

Health and Fitness

Following World War II, the specialized fitness activities of the Federal Government were very shortly discontinued. This included the dissolution of the government-sponsored Joint Fitness Committee in which the American Medical Association, through appropriate representation had played a prominent role. With the return of peace, the strong motivation which had stimulated activity in the field of fitness was quickly lost.

The Trustees of the American Medical Association, however, feeling that fitness efforts were as important in peace as in wartime, sought a way to continue the contribution of the American Medical Association. Their discussion and consideration eventuated in the creation of the Division of Health and Fitness within the Bureau of Health Education of the Association in 1946. In keeping with the philosophy of the medical profession, the name of the Division, as well as the scope of its operations, was broadened to include all aspects of health and fitness as well as the exercise or physical activity phases.
